In diseases arising from the action of septic poisons, of which tetanus and hydrophobia are examples, there may be noticed signs similar to those which follow the administration of certain inhibitory drugs, those which cause inhibition and those which cause the so-called defect of inhibition. My reason for selecting these two is the fact that the signs of each are very well authenticated. An analysis of the symptoms attendant upon true or septic tetanus strongly supports the views here advanced. In tetanus the most prominent and very obvious signs are excitement of the striated muscles, but by careful attention other signs can be detected, which indicate inhibition of the non-striated muscles and viscera. The condition of the striated muscles in this disease is so plainly discernible and generally known that it need not be detailed here. It corresponds with the phenomenon termed defect of inhibition in the nerve-centres controlling the striated muscles. But if the condition of the non-striated muscles is carefully noticed, they appear to be inhibited, through probably their ganglionic nerve-centres. (a) Evidence of this is presented to us by the tendency to constriction of the pupil, so long as death is not imminent; this being brought about by the same physiological cause which induces diminution of the pupil during the action of some inhibitory drugs. Further, there is to be noticed signs showing that peristaltic action of the intestine is deteriorated, as shown by constipation and its evils, retention of solid and gaseous gut contents. Along with these there is retention of urine and diminished visceral excretory products. Thus, during the action of the poison of tetanus there can be noticed signs of inhibition of certain nerve-centres, and the signs of simulated stimulation of other nerve-centres, and during the action of this poison there may also be noticed one very distinctive difference between its effect and that of any inhibitory drugs, that the action of this virus never extends beyond the area of nerves distributed to the non-striated muscles.

This is the probable explanation of the persistent severity of the excitement of certain important striated muscles disturbing co-ordination, so that life is interrupted ere the vitality of the system has been exhausted. If the poison of tetanus had an affinity for, or could exercise any inhibitory power beyond, the sympathetic nerve-area, the excitement of the striated muscles would not be so persistent. In hydrophobia the signs of what has been misnamed defect of inhibition exist "all round," the septic matter being a true or direct stimulant. To explain all the phenomena characteristic of this disease so as to be consistent with the defect of inhibition theory, we must suppose every nerve in the body to possess inhibitory

fibres, and that no nerve is truly automatic, but requires each a "governor."

Most authors who have written upon the etiology and treatment of tetanus and hydrophobia have pointed out that these two distinct diseases have symptoms with similar features, and so close in character, that some authors have suspected them to arise from causes not far allied. But in my opinion there exists not the slightest evidence of relationship beyond the fact that they each have a septic cause of origination. Tetanus is a disease in which limited inhibition decides the cast of symptoms, while hydrophobia is a disease in which true stimulation, not co-ordinately acting, gives character to the present signs. The difference between simulated and true stimulation is that the first is brought on by the inhibition of one nerve centre resulting in the extra accumulation of nerve force in centres not so influenced. True stimulation results from the direct creation of nerve force, and if the whole nerve areas be not influenced then the uninfluenced nerve centres show no signs of diminished energy.

Clinical Records.

ST. MARY'S HOSPITAL.

Case of Cerebellar Tumour.

Under the care of Dr. W. H. BROADBENT.

(Reported by R. H. SCANES SPICER, B.Sc., House Physician.)

E. S., *æt.* 16, domestic servant, was admitted into St. Mary's Hospital on May 31st, 1882, suffering from severe headache, rapidly-developed failure of sight, persistent sickness and amenorrhœa.

History.—Never very strong. Had small-pox five years ago. About May, 1880, commenced to have frequent attacks of headache, more marked in back of head and in morning. In May, 1881, her first menstrual period came on, and her catamenia were regular three following months. Since July, 1881, she has seen nothing, and every ten mornings she has had violent vomiting, bringing up only fluid. In February, 1882—fourteen months ago—she was compelled to leave service on account of severe, constant headache, accompanied by frequent vomiting, and not relieved by it. Since that time she has been living with her parents, and has noticed rapid failure of her sight. Often feels giddy. Sometimes has what she calls "cramp" in limbs and spinal muscles, which makes her bend backwards. Has for about same time had pain in nape of neck, which was sometimes so bad as to wake her from sleep. Never had any fits or convulsions all this time. Sometimes had flushings and sweats. She attended Dr. Cheadle's out-patient department from March 17th, and for about six weeks took a mixture containing pot. brom. and ferri amm. cit. It was during this time that the occasional arching back of the neck was noticed by her mother, and the girl used to say she felt as if something in her head would burst.

On April 18th, 1882, she was sent by Dr. Cheadle to Mr. Anderson Critchett, Ophthalmic Department, for thorough examination of the eyes. Mr. Critchett reported: "R. E. and L. E. each = $\frac{1}{15}$ ft. Field limited in all directions, but can see isolated words of J. 4. Double optic neuritis, the margins of each disc blurred and ill-defined, and in the right eye the nerve fibres are proliferated across the vessels."

No personal or family history of syphilis could be obtained. At the end of May, as patient had not improved, Dr. Cheadle ordered her admission.

Condition on admission.—Is perfectly rational in all her answers to questions, though her memory about the earlier part of her illness is defective. As she lies in bed, the head is drawn back, the sterno-mastoid standing out prominently and rigid. Spine in state of opisthotonos, which is paroxysmal. Patient cannot stand or walk. Her pupils are extremely dilated. No perception of light. No headache now, or pain in neck, except in movement. No sickness. Retraction of abdominal walls. *Tache cérébrale* very distinct. Has difficulty in swallowing anything. Bowels constipated. Heart and lungs normal. On ophthalmoscopic examination by Dr. Broadbent, on June 1st, discs are found to be fairly well defined; pinker than natural; right pinker than left, slightly

(c) South's Chelms, vol. I., page 877. Wood's Practice of Medicine, vol. II., page 784. Copland's Dictionary, Tetanus, page 1,012.

swollen. Ordered calomel, gr. iij., statim. R Pot. iod., gr. xv.; decoc. cinch., ℥j. Ft. m. T.d.s.

June 3rd, 11 a.m.—Condition same as on admission. Patient has taken plenty of liquid diet, as she does not swallow solids very easily. Calomel did not cause action of bowels. Ophthalmoscopic examination repeated. Right disc somewhat swollen. Vessels hidden at points by exudation; well defined, large, and tortuous; no hæmorrhage visible. Left disc not so well seen, but apparently similar. Dr. B. remarked optic neuritis, probably not cause of blindness, which was due to cerebral mischief. Calomel, gr. iij., repeated, and haustus niger, ℥j., post horas tres.—5.30 p.m. Patient's mother was lifting her into a sitting posture in bed when she fell back as if in a fainting fit. Her face was patchy-crimson and white, and her cheek was uniformly flushed. Pulse throbbing. Sighing respiration. Was given spt. am. rom., ℥xx., and brandy ℥ss. In a quarter of an hour she had rallied, and could answer questions. Later she became extremely pallid in the face, pulse almost imperceptible, complaining faintly of intense pain in brows, and died rather suddenly at 7 p.m.

Full account of post-mortem.—Body of a well-nourished girl. Scalp and skull-cap normal. No trace of fracture. On removing dura mater, convolutions somewhat flattened on convexity. No pus or sign of inflammation either on convexity or base. On removing brain, no pus found at base. The pia mater over right half of cerebellum, especially on upper surface of right lateral lobe, is of a marked yellow colour. Whole cerebellum very soft. There is distinct atrophy, and softening of right half of pons and medulla. Forty-four c.c. of fluid escaped from the membranes and ventricles on removing brain. Weight of brain 47 oz. On slicing brain, puncta vasculosa are less conspicuous than normal. Both lateral ventricles greatly dilated, the posterior cornua admitting nearly half the fore-finger. They contain a clear, slightly pinkish serum. Besides pallor, there is no morbid change in rest of cerebrum. On dividing the cerebral peduncle, which appears normal, the cerebellum is seen to be greatly deformed by a tumour extending from the middle line on right side, outwards and forwards, so as to invade the upper $\frac{1}{3}$ of lateral lobe. The tumour is soft, pinkish, red in colour, and measures rather more than 1 inch from before backwards, and $\frac{1}{2}$ inch in width on surface. It was preserved whole for future examination, but was unfortunately destroyed in error. Slight hypostasis of veins of spinal cord. Dura mater distended with fluid, which is perfectly clear. In upper cervical region of cord there is some undue adhesion of arachnoid on upper surface. No tubercle could be seen. Surface of section of cord healthy; no traces of degeneration visible to naked eye in left lateral tract; preserved for microscopic examination. Sub-pleural ecchymoses and punctiform hæmorrhage seen in section of both lungs. Left heart contracted, empty. Right distended with liquid blood. No valvular lesions. Few spots of atheroma at base of aorta and sinuses. Slight staining of inner coat. Liver congested. Spleen normal. Kidneys considerably congested. Both cortex and pyramids of a dark claret colour. Capsule peels off readily. Bladder distended with clear urine. Slight erosions of mucous membrane about os uteri. Mucous membrane of cervix healthy. Cavity contains some blood, which has stained the mucous membrane black.

Remarks.—This case exhibited most of the characteristic symptoms resulting from tumour of the cerebellum, but none which pointed definitely to the part of the cerebellum in which it was situated. When the patient was admitted into the hospital she was unable to walk, so that any peculiarities of gait, or tendency to lurch or fall in any particular direction which may have existed, could not be noted, and no record of such observations was obtainable. The headache, vomiting, and double optic neuritis are common to cases of intra-cranial tumour wherever situate, and to various other lesions. The last-mentioned condition is due, in Dr. Broadbent's opinion, to intra-cranial pressure, operating through sub-arachnoid fluid forced along the sheath of the optic nerve, which strangulates the nerve at the back of the eye. If there is no fluid in the membranes at the base of the brain, as may happen when the ventricles are uniformly distended, or if there is any impediment to access of the fluid to the optic sheath, as by lymph, or by the presence of a tumour in the frontal lobe at its inferior part, there may be no choking of the discs, although the intra-cranial pressure is considerably increased. Again, the so-called neuritis may be present when the intra-cranial pressure is augmented from causes not likely

to give rise to inflammation which could be propagated to the optic nerves, as in a case recently in the hospital, in which there was thrombosis of the left lateral sinus. The symptoms pointing to the cerebellum as the seat of the disease were the loss of vision and the retraction of the head with occasional opisthotonic spasms. If it were not a common experience to see optic neuritis much more severe and much farther advanced, with little impairment of vision, the rapid failure of the sight would be attributed to the changes seen in the fundus of the eye; but here, as in many similar cases, the optic changes could not be accepted as adequate to account for the visual failure, which then became an indication of a central and probably cerebellar lesion. The retraction of the head, again, could scarcely have any other cause than either basic meningitis extending to the medulla and cord, or disease of the cerebellum, the latter of which was clearly pointed to by the history. The production of this symptom Dr. Broadbent considers to be analogous to the exciting of opisthotonic spasm in Ferrier's experiment of stimulating the superior peduncles of the cerebellum. He does not at present see his way to the acceptance of Dr. Hughlings Jackson's hypothesis of antagonistic cerebral and cerebellar influence. The sudden death is extremely characteristic of cerebellar disease; it is due in such cases to impaction, directly or indirectly, of the medullary centres of the great vital reflexes. The sub-pleural hæmorrhages observed are common after this mode of death. It would be an interesting speculation to endeavour to estimate the relation between the catamenial irregularity and the tumour in the cerebellum, but this cannot be entered upon.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

M. BROUARDEL read a paper, at the Paris Academy of Medicine, for MM. Charles Bouchard, Capitan, and Charrin, on "The Cultivation of the Glander Microbe, and the Transmission of this Disease by the aid of Cultivation Liquids." After MM. Christal and Hiener had first, in 1868, proved the presence of a microbe in glanders, they discovered that it existed not only in portions exposed to the air, such as nasal ulcerations, and pulmonary abscesses, &c., but also in those not exposed—for instance, spleen, and liver. The constant presence of these germs, and their always possessing the same characteristics, is sufficient reason for presuming that they have an important part to play in the production of disease; to show that this is really the case, it became necessary to reproduce the disease in animals by inoculating them with germs obtained otherwise than from the diseased subject. The authors of this paper succeeded in obtaining the multiplication of the microbe of glanders from man, horses, and guinea-pigs, by neutralised solutions of beef extract, kept at a temperature of 37°. By the aid of repeated cultivation, they obtained at the eighth culture the microbe pure and free from any mixture, but this increase did not appear in the vessels which were exposed to the air. Previous experiences show that during the first and second times of cultivation the microbe retained the virulent properties of the glander poison. The disease produced in the guinea-pig was, from both a clinical and anatomical point of view, exactly similar to that developed in the same animal by morbid products taken directly from the horse. Finally, the conclusions deduced from sixty-one experiments practised on other animals confirmed the foregoing testimony. Glanders is the second disease of man of which the parasitic nature has been proved, "charbon" having been the first.

TYPHOID FEVER.—The inexhaustible subject of typhoid fever is still occupying the attention of the Academy of Medicine, and absorbing all its time. Two members, M. Peter

and M. Rochard, entertained the meeting with their views on the treatment and prophylaxy of the disease. The former, who was frequently applauded, made a very spirited speech, in which he criticised what he called systematic treatment, and especially cold baths, so much used by Brand in Germany. He humorously compared certain medical men to the fire brigade, ready to throw water on the slightest rise in the temperature. He had two cases himself, in which the temperature rose to 106°, and both got well without any treatment. Yet he considered that in certain, but rare cases, the cold bath, at least, sponging with vinegar, might be used with benefit. He begged his colleagues to treat symptoms, and not to lend themselves to systematic medication.—M. Rochard followed up with some well considered remarks on the prophylactic treatment. To show the importance of the question, he gave the mortality of the late epidemic, 3,276 deaths were registered in the last year, of which 1,449 occurred in the hospitals and 1,827 outside; the same malady caused 2,120 deaths in the preceding year, or 1,556 less. The total number of cases treated in the hospitals in 1882 was 9,361, the sojourn of the patients in these establishments represented 240,083 days, at three shillings, which made a total of something over forty-six thousand pounds, which had to be defrayed by the town. If to this sum were added forty-six thousand pounds for the days lost during convalescence, it will be found that the total expense of the hospitals for the treatment of this disease alone represents a sum of seventy-six thousand pounds. As to the mortality, he calculated that death was a loss to the city of two hundred and forty pounds, but he knew that this valuation was very low. However, at that figure, the capital lost to Paris amounted to seven hundred and eighty-six thousand pounds, which sum added to the cost of treatment already mentioned, formed a grand total of a million sterling. His reason for bringing forward these statistics, was to show that if the authorities spent more money in sanitary measures, the economy to the city, not to speak of the state, if the value of men were to be reckoned in money, would be considerable. M. Rochard concluded by saying that France had need of her men, the French are not so prolific as the Chinese, already the number of the population cannot maintain itself except by immigration.

RELATION OF HEREDITARY SYPHILIS TO RICKETS.—At the Société de Chirurgie, M. Parrot gave, in a lengthy communication, his views and experience on the above subject. The causes of the last-named affection hitherto given, were very variable, scrofula held the foremost rank. Guérin put it down to nursing too long, others considered that it resulted from giving meat too soon, Bouchut accused enteritis, but he (M. Parrot) had often seen children affected with that malady who showed no symptoms of rickets. After developing his ideas on the question, M. Parrot concluded by affirming that where there was no germ of hereditary syphilis, rickets were never seen. This rather rash assertion was attacked by M. Magitot, and was followed by M. Després, who said he had often seen children affected with rickets whose parents were well known to him and could not have been suspected of having syphilis. The erosions of the teeth, on which M. Parrot based all his proofs, were to be met with in different other affections, and could not be relied on as evidence conclusive of syphilis; and on the other hand, he had seen children manifestly syphilitic who did not present this lesion of the teeth.

HYPOGASTRIC LITHOTOMY.—M. Combalat, of the Hotel Dieu, Marseilles, performed, last week, hypogastric lithotomy, and although the subject was far from being favourable to that or any other operation, it was attended with good success,

affording another proof of the superiority of that method to the ordinary perineal operation. The patient not only was of an advanced age, 73, but also had a cardiac affection with œdema of the extremities. Further, having been an old soldier, he led an irregular life, and had at various periods suffered from alcoholism. Brought to the operating table and chloroform being administered in spite of the pronounced mitral insufficiency, M. Combalat having previously placed a caoutchouc bag in the rectum to throw forward the bladder by distension, made an incision six inches in length, commencing about an inch and a-half below the umbilicus and extending in the median line to a little above the pubes. The adipose tissue was very thick in this region, being nearly an inch and a-half in depth, the other tissues cut through were drawn aside by retractors, and immediately the bladder, which had been distended by a 4 per cent. solution of boric acid, bulged forward, and an opening was made on the director large enough to admit two fingers. The stones, for there were two, were easily extracted. M. Combalat thought better not to suture the bladder, he abandoned it to itself after passing two long drainage tubes *in situ*. The external wound was closed by the interrupted suture except at the lowest part in order to give exit to the drains. The whole operation was performed in less than an hour, and Lister dressing was rigorously applied. This is the seventy-first lithotomy that the learned professor of the Hotel Dieu has performed, and he is of the opinion that when the patient is over sixty, hypogastric lithotomy should be exclusively performed.

TREATMENT OF CHRONIC DIARRHŒA.—M. Gubler recommends the exhibition of oxide of zinc. He has found it most useful in the diarrhœa of phthisis, and whenever ulceration of the uterus is suspected. He gives it in powders in the following form: oxide of zinc, thirty grains; bicarbonate of soda, ten grains; in four powders, two or three daily.

Transactions of Societies.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 1ST.

B. WALKER, M.R.C.S.E., President, in the Chair.

CHARCOT'S DISEASE.

MR. ATKIN, House-Surgeon at the Sheffield General Infirmary, showed a very interesting example of this disease, occurring in a man advanced in middle age. There was a history of syphilis. Other symptoms, such as lightning pains, &c., &c., pointed to the co-existence of locomotor ataxy. The effusion into and around the right knee-joint, together with the power of dislocating the joint in the antero-posterior direction, were very marked. There was also considerable lateral movement. The pupils were contracted, and reacted very slowly to the stimulus of light. Another interesting feature in the case was the want of proper control over the bladder. The patient never knew when he wanted to make water, or when making it when to leave off; the water was jerked out with each respiratory movement. The condition of the patient was lamentable, but as a pathological specimen most interesting.

VEGETATIONS IN THE MITRAL AORTIC VALVES: OSSIFIED CYSTIC KIDNEY.

DR. LAW exhibited three specimens of the heart and kidney taken from one subject. The vegetations were beautifully marked examples of this nature. That in the mitral valve was about the size of half a haricot bean, and that in the semi-lunar valve was about the size of a small-sized pea. Loud valvular murmurs had been heard during life in connection with these growths. The kidney (the left) was a most interesting specimen. There was almost complete loss of the kidney structure; the organ was shrunken to one-

fourth the size of a healthy kidney, and was ossified throughout the remaining tissues. The existence of such a state of matters was not detected during life.

CANCER OF THE STOMACH.

Dr. LAW exhibited also a well-marked example of sarcomatous disease of the stomach.

INFANTILE PARALYSIS.

Dr. GWYNNE read a paper on this subject (which will be found at page 268), which gave rise to an animated discussion, in which Drs. LAW, BUNEAM, and DYSON took part.

In the course of his remarks, Dr. DYSON called attention to the following points:—1. The frequency with which sensation was said to be intact in infantile paralysis. In an adult case recently under his care there was decided diminution of sensation. He pointed out the great difficulty that existed in testing sensation in children. 2. The relationship of the more chronic varieties to progressive muscular atrophy, the differences in electrical reaction being explicable on the understanding that the lesion in the one case seems massive and general in the anterior cornua; in the other, more gradual and detailed, affecting separate cells. 3. He recommended in the treatment of paralysis and atrophy a more frequent and careful use of massage and warm water, and the covering of the affected members with warm clothing.

In connection with the paper, Mr. ATKIN exhibited for Mr. A. JACKSON, Surgeon to the General Infirmary, a specimen of a leg, amputated below the knee-joint, in the case of a young woman, *æt.* 21, who had been the subject of infantile paralysis, and who desired its removal, as it was a useless burden to her. The limb presented an example of arrested development, and of complete fatty degeneration of all the muscles. There was not a trace of muscular tissue present.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, MARCH 5TH.

JOSEPH WALKER, M.D., President, in the Chair.

EPULOID GROWTHS.

MR. BOYD WALLIS showed some models, illustrating the treatment of epuloid growths by means of electrolysis. In one case—that of a lady, *æt.* 58, who had obstinately refused to submit to any operation with the knife—an epulis of six years' growth, and of considerable size, springing from the back of the upper jaw, had been entirely removed by this means. The treatment, however, extended over six months. Another softer and more vascular growth had been destroyed by electrolysis in six sittings.

"THE ST. LUKE'S MYSTERY."

Mr. J. S. TURNER exhibited models of the mouth of the girl whose body was left, packed in a box, at a carrier's office in St. Luke's about two months ago; he showed also her lower jaw. Some doubt as to the girl's age was at first caused by the fact that on the right side of the upper jaw there were three molars, and the first of these was thought to be a permanent tooth. It was, however, a temporary molar, and the second bicuspid, which it was thought had been removed to relieve over-crowding, had been retarded in its eruption. In the lower jaw there were two temporary molars remaining; the canines, both upper and lower, were fully in position, and so were the upper anterior bicuspids. Taking everything into consideration, he thought the girl must have been about 14 or 15 years of age.

The case gave rise to some discussion, in which Mr. CHAS. TOMES, Mr. COLEMAN, and Mr. HUTCHINSON took part.

Dr. J. C. THOROWGOOD then read a paper on

THERAPEUTIC AGENTS FOR THE PROMOTION OF OSSEOUS DEVELOPMENT.

Dr. THOROWGOOD pointed out that the composition of the bones and teeth was practically identical, the chief difference being the larger proportion of inorganic matter in the teeth. The analysis showed that a considerable quantity of mineral food was required for the nutrition of these tissues. The mere administration of the necessary lime salts was, however, by no means the only thing to be considered in striving to improve osseous development. Thus,

in rickets, with an evident deficiency of lime salts in the bones, there was an elimination of from four to six times the normal amount of lime in the urine, showing that the defect was in the process of assimilation. For the dentist, the most serious condition in children was one of acid dyspepsia: the child's breath had a sour smell, tongue furred with red papillæ showing through, appetite often voracious, and bowels confined or irregular. To give a big-bellied, pale-faced child in this condition phosphate of lime and iron would only make him more uncomfortable; but give him alkaline aperients, regulate his diet, cutting off excess of starch and sugar, order exercise, salt-water baths, &c., and then administer the specific remedies indicated. Of these, the most useful were the soluble hypophosphite of lime and the chloride of calcium; either of these might be given in doses of two or three grains in glycerine and water. The lacto-phosphate of lime was also a valuable remedy. Diet was most important; the child must be taught to eat slowly; brown bread and Scotch oatmeal would suit some children, and "seconds" flour was preferable to "best whites." By this line of treatment the child would be brought into a condition in which the dental surgeon could work on the decayed molars with some prospect of his work remaining a lasting proof of his skill. Dr. THOROWGOOD, in conclusion, touched upon the subject of infant feeding.

An interesting discussion followed, several members pointing out that, owing to the early development of the teeth, and to the fact that, when once formed, they did not alter appreciably, any treatment intended to improve their condition must be effected through the mother, so as to influence the child during the periods of pregnancy and lactation.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

A MEETING of the Surgical Section was held on Friday evening, the 9th ult., in the Albert Hall, Royal College of Surgeons, Mr. J. K. BARTON, President, in the chair.

Mr. WM. STOKES, Sectional Secretary, and Mr. WM. THOMSON, General Secretary, were in attendance.

AXILLARY ANEURISM.

Dr. T. E. LITTLE read a paper on a case of axillary aneurism, for the cure of which he had deligated the subclavian artery in its third stage. The tumour had a traumatic origin. Great difficulties surrounded the diagnosis of the case, owing to the almost complete absence of pulsation or bruit in the tumour; nor could pulsation be felt at the wrist. There was a division of opinion among the surgeons who had been asked to examine the case, but ultimately the diagnosis of aneurism was arrived at. The operation selected and performed by Dr. Little was ligation of the third stage of the subclavian, the vessel being reached by an infra-clavicular incision. The result of the operation was most satisfactory.

Dr. BENNETT dwelt on the difficulties that attended the diagnosis in this case, being at one time of opinion that the tumour was of venous origin. He subsequently, however, modified this view. In deligating the first stage of the axillary artery he pointed out the advantages of keeping above, and not below, the cephalic vein.

Mr. STOKES asked the author what were his reasons for selecting the infra-clavicular operation; one which, in Mr. Stokes' experience, was much more difficult than the operation above the clavicle. He also mentioned that the probabilities of finding the artery healthy were greater when distant operation was performed.

Mr. PORTER considered the Academy indebted to Dr. Little for his excellent description of the operation. He believed the deligation of the first stage of the axillary artery was a more difficult operation than that of the third stage of the subclavian. He agreed with Dr. Bennett that the vein gave a great deal of trouble, as a rule, and that the surgeon must with great caution pass either the aneurismal needle or the probe between them.

Mr. CROLY dwelt on the difficulty of the operation, mainly from the great depth of the vessel. It had been suggested in order to facilitate reaching the vessel to saw across the clavicle. The collapse of the aneurism after the operation was not a favourable sign. The case appeared to have many features of resemblance to that of an aneurismal varix. The occurrence of pulsation in malignant tumours he also mentioned.

Dr. LITTLE, in reply, observed that, to give some colour to what Mr. Croly had said, it appeared to him that the pulsation in the vein at the time was intrinsic. He gave his reason for selecting the infra-clavicular operation, stating that the indications to keep away as far as possible from the aneurism were not specially great, as the aneurism had a traumatic origin. He agreed with Mr. Croly that the collapsing of the aneurism on the application of the ligatures was an unfavourable sign.

STRANGULATED HERNIA.

Dr. KILGARRIFF read the notes of three cases of strangulated hernia which had been operated on by him. The first was remarkable from the nature of the contents of the hernial tumour, consisting of the cæcum, and portion of the ascending colon in the cæcum having a free meso-cæcum, and the protrusion having a complete sac. The second case was one of congenital hernia, and presented many features of interest. The spermatic cord had a diameter of $\frac{3}{4}$ -inch, and was slung by a distinct and free mesentery. Again, the rigid, inelastic condition of the skin of the patient rendered the replacement of the testicle impossible, and necessitated castration. In the third case there was a double stricture, the external consisting of thickened inter-columnar bands, and the second at the deep abdominal ring. The results obtained in these three cases were satisfactory.

In the discussion which followed, Mr. Ormsby, Dr. T. E. Little, Dr. Henry D. Fitzgibbon, Mr. Croly, the President, and Mr. Stokes took part. They drew attention to the after-treatment in cases of strangulated hernia, to the frequent possibility of reducing hernia after opening the sac without division of the stricture, to the possible connection of serous effusion in the sac and extreme tightness of the stricture, and to the desirability of making a high incision in the congenital form.

Dr. KILGARRIFF briefly replied.

The Section then adjourned.

THE MEDICAL SECTION.

A MEETING of the Medical Section was held on Friday evening, March 16th, at the Hall of the King and Queen's College of Physicians, Dr. WILLIAM MOORE, President of the Section, in the chair.

Dr. A. N. MONTGOMERY, Sectional Secretary, was in attendance.

LIVING SPECIMENS.

Dr. McDONNELL exhibited a case of hammer-cramp; and Dr. STORY a case of hematrophia facialis.

SPECIMENS EXHIBITED BY CARD.

Dr. C. J. NIXON—Intussusception of the death struggle.

Dr. J. W. MOORE—Disease of the aortic valves, with compensatory mitral regurgitation.

Dr. HAWTREY BENSON—Abscess in wall of bladder, which pointed externally.

COMMUNICATIONS.

1. Dr. FRAZER on "Bleeders" and sudden death from cerebral hæmorrhage. 2. Dr. McDONNELL on hammer-cramp.

Dr. FRAZER read a paper, mentioning some instances of serious bleeding following trifling injuries, and then described two cases of sudden death from sanguineous apoplexy occurring in individuals who had previously suffered from bleeding of the nose, lungs, &c.

Dr. HENRY KENNEDY related a fatal case of purpura, in which the post-mortem examination revealed an extensive effusion of blood over the surface of the brain; and he referred to Latour's observations on hæmorrhage.

Dr. COX referred to a gentleman the subject of hæmorrhagic diathesis, in which a chill appeared to be invariably the exciting cause of the hæmorrhage. In this case there was a well-marked family history of the diathesis.

The PRESIDENT mentioned a case of an old lady who suffered from severe epistaxis, and shortly afterwards became completely demented.

Dr. FRAZER, in reply, said he introduced the first two cases merely to show that he was not overlooking the subject of hæmorrhagic diathesis. In such cases the blood was almost water, but in the case of the gentleman pointedly alluded to he never saw better clotting blood. The hæmorrhage in his case was not produced by chill, but he appeared

to form more blood than was required, and this was eliminated by nose, lungs, or kidneys.

Dr. R. McDONNELL showed to the Section a patient, a young man 22 years of age, whose right arm was subject to muscular spasms. The patient was a nailor by trade, and had been, since he was eleven years old, more or less hard at work at this occupation. The spasmodic jerkings of the muscles, which interfered with his occupation, began about seventeen months ago, and after the first three months became so violent that he had to give up work altogether. The case was one of functional spasm unaccompanied by pain, and is an affection very similar to writer's or scrivener's cramp, although all the muscles supplied by the brachial plexus seem to be affected, and those around the shoulder-joint, especially the great pectoral, seem to be most so. The treatment consists in regular, orderly rhythmical movements of the limb, as was so successful in a very similar case reported by Dr. G. V. POORE in the *Practitioner*, September, 1872.

Dr. FOOT said that this man had been under his care for a considerable period, during which time there was a marked improvement in his symptoms. He did not consider it at all a wonderful case. He thought it was analogous to other cases, such as telegraphists', milkers', violin and pianoforte-players'. He was not aware that it differed from several cases recorded by Dr. Frank Smith, of Birmingham, which was a centre of nail-making. He never thought there was any approach to chorea, as when in bed the muscles were perfectly quiet.

Dr. HENRY KENNEDY remarked that Dr. Harley had succeeded in curing similar cases by large doses of *s. conii*, $\frac{5j}$, at a single dose.

The PRESIDENT and Dr. F. C. MOORE having also taken part in the discussion,

Dr. McDONNELL replied. He said that there were two points raised by Dr. Foot in reference to the case. First, there was no difference of opinion as to the nature of the case, which belonged to the category of scrivener's palsy, but differed from the tremor in piano-players, &c. His case also differed from those of Dr. Frank Smith in not having general paralysis. Dr. Smith's cases bore no relation whatever to scrivener's cramp or hammer-cramp. The second point was that Dr. Foot did not seem to think that the case belonged to chorea, because the patient was quiet at night. But so far as his (Dr. McDonnell's) experience went, in any except the most exaggerated case of chorea, the movements were entirely stopped during sleep.

The Section adjourned.

Special.

THE REPORT OF THE MEDICAL DEPARTMENT OF THE ENGLISH LOCAL GOVERNMENT BOARD.

THE supplement to the eleventh annual report of the Medical Department of the Local Government Board just issued is a valuable contribution to hygienic medicine, and on that account demands a prominent notice. We shall not, however, attempt on the present occasion a digest of the varied contents of the volume; our remarks will be confined to a subject which has engaged, as our readers know, a good deal of our attention—that of the purity of potable waters. Investigations were undertaken more than a year ago by the Medical Department of the Board, with the view of showing what dependence may be placed on the chemical analysis of water. This question would, in all probability, not have assumed the importance it has but for the persistent way in which, in the columns of the *Medical Press and Circular*, we have maintained that analytical results alone were of little or no value as proving purity and wholesomeness of water, and this view is now placed beyond a doubt.

The investigations carried out under the superintend-

dence of Dr. Cory, whose report is printed *in extenso*, had for their object the testing the evidence derivable from chemical analyses after adding various polluting matters to a series of samples of waters, and submitting them, together with samples of the original waters, to selected experts for examination. Dr. Cory kept accurate note of each step of the proceedings of the chemists, and also of the microscopical appearances observed in his water samples, and he now lays the facts before the Board. Many of his observations had reference to the contamination of water with the stools of enteric fever patients, this disease having a manifest and special faculty of spreading by means of drinking water. Dr. Buchanan, in commenting upon the report, selects these as being more convenient for the purpose of showing some of the results obtained by the experiments. In the first place, it was found, as has been often stated, that by the customary methods of chemical examination there is nothing whatever to distinguish typhoid pollution from that of any other excremental pollution; indeed, there is no indication whatever that chemistry can tell whether a healthy or a diseased body has been the source of any foulness observed in water. This remark applies to all the various chemical processes put on their trial in the course of these experiments, that is, equally to the "permanganate test," the "albuminoid ammonia," and the "combustion process," all of which were used. Dr. Buchanan restricts his remarks to the results obtained by the process which is most trusted for the recognition of animal or organic "impurity, the amount of albuminoid ammonia yielded by the water." Without entering into the details of the experiments, we may state that a water purposely befouled by adding one grain of enteric fever stool per gallon yielded results, as expressed in albuminoid ammonia, as low as .014 parts per million parts of water. Dr. Buchanan is of opinion, therefore, that it is not permissible to accept the doctrines which have been formulated from the amount of albuminoid ammonia present in an otherwise unknown water. Polluting material potent for harm may be in a water yielding from 0.0 up to 0.05 parts of albuminoid ammonia per million without removing it from the rank of waters of "extraordinary organic purity," and he positively denies that an unknown water showing 0.05 to 0.10 parts of albuminoid ammonia per million can be assumed to be "safe organically." Water containing the most dangerous ingredients may then escape the observation of the chemist—not so the microscopist, for in almost every instance the microscope detected living organisms in the excremental polluted specimens under experimental examination. "The lesson taught afresh and significantly by these investigations is that, while we must be ever on the watch for the indications that chemistry affords of the contaminating matters to drinking waters, we must go beyond the laboratory for evidence of any drinking water being free from dangerous organic pollution. For unless the chemist is well acquainted with the origin and liabilities of the water he is examining, he is not justified in speaking of a water as "safe or wholesome" if it contains any trace whatever of organic matter; hardly, indeed, even if it contain absolutely none of such matter appreciable by his very delicate methods. The chemist can, in brief, tell us of impurity and hazard but not of purity and safety." There are many other interesting investigations which we must reserve for a future opportunity.

THE MEDICAL BILL.

Analysis of the Bill (all important phrases verbatim) introduced in the House of Lords by Lord Carlisle on behalf of the Government on Thursday, 8th of March.

(Continued from page 254.)

THE following is an analysis of the clauses of the Bill additional to those which we published last week:—

PART III.

Foreign Practitioners.

22. Where a person shows that he holds some recognised colonial diploma, and that he is of good character, he shall be entitled, without examination, to be registered as a colonial practitioner;

Provided—

- (1.) That he was practising medicine in the United Kingdom on Jan. 1, 1885, and that he has continuously practised the same either in the U. K. or elsewhere for the preceding ten years; or
- (2.) That his diploma was granted to him when he was not domiciled in the U. K.

23. Same enactment as regards foreign practitioner;

Provided—

- (1.) That he is not a British subject; or
- (2.) That being a British subject his diploma was granted when he was not domiciled in the U. K. or resident out of the U. K. not less than five years; or
- (3.) That being a British subject he was practising in the U. K. on Jan. 1, 1885, and that he has so practised for the preceding ten years.

24. The recognised medical diplomas shall be such medical diplomas as may be recognised by the Medical Council as furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery, and as entitling the holder thereof to practise medicine, surgery, and midwifery in such British possession or foreign country.

PART IV.

Medical Titles.

26. Any registered medical practitioner who has passed a final examination under this Act may use after his name the title of Licentiate of the Medical Council in medicine, surgery, and midwifery, or any letters indicative of such title.

27. Medical titles shall be divided into two classes—

- (a.) medical qualifying titles, and
- (b.) medical higher titles,

and these alone shall be entered on the Register.

"Medical qualifying title" means—

- (a.) In the case of a home practitioner the title of "Licentiate of the Medical Council in medicine, surgery, and midwifery;" and
- (b.) In the case of a colonial or foreign practitioner any title implying that he has obtained a recognised diploma;

As respects a person registered before Jan. 1, 1885—

Any title implying that he has obtained a registrable diploma.

"Medical higher title" means any title implying the grant of a diploma after examination in respect of a substantially higher degree of knowledge than is required to obtain a qualifying diploma, or a diploma which has been granted as a testimonial of special distinction.

If any authority feels aggrieved by refusal of the Council to recognise its diploma as conferring a medical higher title, such body may appeal to the Privy Council.

Management of Register.

29. Arrangements for correction and publication of Medical Register as heretofore.

Where the Medical Council is of opinion that the

erasure of the name of a person from the Register will be too severe a punishment for the offence of such person, they may, instead of directing his name to be erased, declare that he is suspended, and thereupon directing the word "suspended" to be entered opposite his name in the Register.

A registered medical practitioner when suspended shall not be deemed during such suspension to be a registered medical practitioner.

The name of a person shall not be erased nor suspended under this section—

- (a) For adopting the practice of any particular theory of medicine or surgery, nor
- (b) For a conviction for a political offence abroad, nor
- (c) On account of a conviction for an offence which, does not, either from the trivial nature of the offence, or from the circumstances under which it was committed, or from the time which has elapsed since its commission, disqualify a person in the opinion of the Medical Council.

PART VI.

GENERAL PROVISIONS.

As to Medical Boards, Medical Council, and Privy Council.

40. Each medical board may, with the assent of the Medical Council, appoint and remove a secretary, treasurer, and such other officers and servants as the medical board may require.

41. The Medical Council may from time to time, with the sanction of the Privy Council, do likewise.

As to Approval and Confirmation of Schemes.

42. Where a scheme is required to be approved by the Medical Council—

- (1) The medical board shall send a copy to the Medical Council.
- (2) The Medical Council may either annul or approve the same with or without modification made by the Council, or may remit the same to the medical board for modification by them, until it is brought into conformity with the views of the Medical Council.
- (3) The Medical Council to forward as soon as practicable to the Privy Council for confirmation any scheme approved by the Medical Council.
- (4) The Privy Council shall take the same into their consideration, and may either annul the same altogether, or may remit the same to the Medical Council for modification by them.

The Medical Council before approving and the Privy Council before confirming any scheme shall hear any objections which may be made to the scheme by any person or body of persons.

44. If any medical board makes default in the performance of its duty, the Medical Council shall notify to the medical board that it has made such default, and may by order suspend or supersede such board, and direct a fresh election to be held.

45. If the Medical Council makes default in the performance of its duty, the Privy Council shall notify that it has made such default; and the Privy Council may do any act or thing in respect of which it considers the Medical Council to have been in default.

PART VIII.

Saving Clauses.

67. Nothing in this Act contained shall in any way prejudice or affect the lawful occupation or business of chemists, or druggists, or so far as relates to selling, compounding, or dispensing medicines, the rights, privileges, or employment of duly licensed apothecaries in Ireland.

68. Nothing in this Act contained shall prevent any person not a British subject who has obtained a foreign degree or diploma entitling him to practise medicine, surgery, and midwifery in his own country, from acting as the medical officer of any hospital for the relief of foreigners in sickness, although he is not registered as a foreign practi-

tioner, provided that such person is engaged in no other medical practice.

69. Nothing in this Act contained shall repeal or alter any of the provisions of the Passenger Act, 1855.

70. This Act shall not increase or diminish the privileges of any person who, on December 31, 1884, is a registered practitioner, and such person shall be entitled to practise in medicine, surgery, and midwifery, or in any one or more of them, according as he was entitled to practise in such callings or any one or more of them, before the said appointed day, but not further or otherwise.

Dentists.

72. There shall be repealed so much of the Dentists' Act, as provides that a prosecution shall not be instituted by a private person, and a prosecution for any such offences may be instituted by a private person accordingly.

It shall be lawful for Her Majesty at any time after the said appointed day to declare by Order in Council that section twenty-eight of the said Dentists' Act, 1878, shall be in force on and after a day to be named in such order, but in the meantime and until such Order has been made, and before such day as last aforesaid, such section shall not be deemed to be in force.

SCHEDULE.

PROCEEDINGS OF MEDICAL BOARD AND OF COMMITTEES OF MEDICAL BOARD AND MEDICAL COUNCIL.

1. The board or council shall from time to time make such regulations with respect to the transaction and management of business as they think fit, subject to the following conditions:—

- (a) An extraordinary meeting may be summoned at any time on the requisition of three members addressed to the chairman;
- (b) The quorum shall consist of not less than three members;
- (c) Every question shall be decided by a majority of votes of the members present and voting on that question;
- (d) The names of the members present at a meeting, and upon a requisition made by any member or members voting on a question the names of the members voting on that question, shall be recorded.

2. In case of an equality of votes at any meeting the chairman for the time being of such meeting shall have a second or casting vote.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 34, Madras 39, Paris 28, Geneva 19, Brussels 25, Amsterdam 27, Rotterdam 34, The Hague 15, Copenhagen 27, Stockholm 28, Christiania 9, St. Petersburg 41, Berlin 25, Hamburg (State) 27, Dresden 24, Breslau 29, Munich 28, Vienna 32, Prague 37, Buda-Pesth 32, Trieste 37, Rome 31, Turin 28, Venice 30, Lisbon 34, New York 25, Brooklyn 21, Philadelphia 20, Baltimore 21.

THE highest annual death-rates per 1,000 last week from diseases of the zymotic class, in the large towns, were—From whooping-cough, 2·3 in Cardiff and 3·8 in Hull; from scarlet fever, 1·2 in Sheffield and 1·3 in Leeds; and from "fever," 1·0 in Newcastle-upon-Tyne, 1·2 in Birkenhead, 1·5 in Liverpool, and 2·1 in Plymouth. The 37 deaths from diphtheria included 18 in London, 6 in Glasgow, 3 in Edinburgh, and 2 in Portsmouth. Small-pox caused one death in London, 3 in Newcastle-upon-Tyne, 2 in Birmingham, and one in Hull.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 28, 1883.

THE MEDICAL BILL.

THE licensing bodies concerned with the Medical Bill have been engaged upon the measure during the past week, and are meditating upon the attitude which they will assume towards the second reading of the Bill, which is set down for April 5th. As regards the long and bitterly-contested reconstitution of the Medical Council, and the election thereto of direct representatives of the medical practitioner, there seems to be no longer any serious opposition. The Medical Council and its champions, Mr. Simon and Mr. Turner, against the profession have, we imagine, fired their last cartridge, and the licensing bodies are too busy entrenching their own positions to care about the dismemberment of the Medical Council, so that it may, we believe, be assumed that, if the Bill passes at all, it will pass with the reconstitution clauses very much as they stand. The quacks' clauses are open to much improvement, and no doubt a vigorous effort will be made to amend them when the Bill reaches the committee stage, but we believe that those who are most anxious about this part of the Bill will not offer any opposition to the second reading, but will reserve their efforts until the subsequent stage.

We publish to-day our analysis of the foreign and colonial diploma clauses of the Bill, but though we have much to say with reference to them, we think it better to withhold our criticism until the time comes for suggesting alterations.

The points upon which the battle of the Bill will be fought are the clause which is to secure equality of curriculum, examination standard, and examination fee at the final examinations of all divisional boards throughout the kingdom, and the clause which provides for the distribution of the surplus for the maintenance of the educational and examining bodies. We are not surprised that these clauses should have evoked the solid opposition of the Irish qualifying bodies, and we regret that the Government were not better advised as to the effect of them upon these bodies before they framed them in their present form. As they now stand they perpetuate the Scotch under-selling, and they leave the Irish licensing bodies wholly dependent on the good will of the Medical Council in London for a great part of their means of support. We do not conceive that this result of the clauses could have been intended, because such a settlement would be entirely at variance with the principle of former bills, and with the plain details of justice and public interest. We therefore look with confidence to an amendment of the Bill on these points with the consent of the Government, and we anticipate that, if the Irish bodies can be satisfied on these two subjects, they will permit the Bill to go through at least without active resistance.

Subject to this change in the Bill, we consider it to be in all essential respects deserving of the support of the profession, and we hope that support will be heartily and energetically given if the amendments to which we refer are conceded.

INTRA-CARDIAC DISEASES.

HOWEVER much Dr. Sansom may differ from other observers in his interpretation of the phenomena exhibited during the progress of cases in which the endothelial structures of the heart are the seat of lesion, there can still be no question of the importance and value of his recent contributions to our knowledge of certain cardiac diseases. In the Lettsomian Lectures recently published in our columns, Dr. Sansom has done something more than merely review the information at present accessible to practitioners in respect to cardiac valvular diseases; much of the time during which he occupied the position of instructor of the Medical Society of London was devoted to an exposition of results and opinions gathered in a long and fruitful experience of the affections treated of in the lectures. It was natural, however, if not unavoidable, that primary importance should throughout them be given to the relations existing between rheumatic fever and valvular mischief; and we may congratulate ourselves on the forcible manner in which Dr. Sansom has felt it to be imperative on him to insist that intra-cardiac mischief may be induced without the exhibition of any of those directly referable symptoms that are mentally conjured up by mention of acute rheumatism. We have again and again asserted, not, indeed, of this affection specially, but generally, that by far the worst of all existing evils in medical practice is that "leave it to others" system, in accordance with which the beginnings of diseases are regarded as a thing apart from the necessary studies of practitioners. Unpalatable as the truth may sound, it is yet undeniable

that medical men, as a rule, are disposed to look upon themselves as required to act only in the presence of illness, and to relegate to scientists and specialists and preventists all those questions involving the command "*principiis obsta*," and of which it is their duty to take full cognisance.

Dr. Sansom has shown that rheumatism does not stand alone as the disease with which endocarditis is to be associated. After both measles and scarlatina he has found it to be insidiously developed; and so convinced is he of the dangers possible in this connection that he urges vastly more careful treatment of cases of measles than these are in the habit of receiving; and in the belief he entertains of the frequency with which cardiac troubles are assignable to premature exposure after recovery from "simple measles" there may not improbably be many sharers among his more thoughtful listeners.

Much interest must naturally attach to the bearing of Dr. Sansom's teachings on the salicylic treatment of rheumatism initiated by Dr. MacLagan; nor does it seem improbable that one outcome of the lectures and the discussion they have given rise to, may be a better understanding of the rôle of salicin, and thereby a more specific application of its curative properties. Dr. MacLagan requires the drug to be pushed in what bears the semblance of heroic doses, basing his arguments to this end on strictly pathological grounds. The salicin, he urges, cuts short the stage of primary mischief if given early and in sufficient amount, such primary changes consisting in cellular changes of the fibrous tissue about the region of the valves. Once developed, this infiltration causes friction of, and deposits on, the valve itself; and hence his first rule is to prevent such friction by arresting the stage of infiltration which precedes it. There is little in Dr. Sansom's lectures to preclude us from accepting Dr. MacLagan's views, or from indulging the desire to see treatment designed more especially to vindicate his statements in the future—a consummation to be wished for in the best interests of medicine.

Mitral regurgitation and mitral stenosis formed the subjects of Dr. Sansom's second and third lectures, both diseases being carefully and exhaustively considered. Speaking of remedial agents in regurgitation, he refers favourably to *convallaria majalis*, which, though doubtfully superior to *digitalis*, has power, in Dr. Sansom's experience, to raise intra-vascular pressure and the force of contraction of the heart.

The difficulty often experienced in recognising stenosis of the mitral valve has induced Dr. Sansom to devote considerable space to explanation of the differential diagnosis of the disease, and the lecture containing it will be found of the utmost service to students and practitioners. Many even of the latter might be and have been guilty of excusable misjudgment in these cases; and we venture to say that, though remembering the golden rule that murmurs due to stenosis stop abruptly with the first sound, difficulty may, notwithstanding, be sometimes experienced, and that too by observers of considerable experience and knowledge. To all such, however, the perusal of Dr. Sansom's exposition of the signs and character of stenosis will prove an unmixed blessing.

The statistics by which Dr. Sansom shows the relations between rheumatism and the two forms of mitral malfor-

mation considered in the last lectures are most instructive. They prove that proneness to mitral regurgitation increases with the number of rheumatismal attacks, whereas such attacks have no tendency to cause stenosis; but when the disease as occurring in children is studied, the fact comes out, so emphatically suggestive in connection with the remarks made at the commencement of this article, that stenosis is most probably not independent of rheumatism, but is associated with its most insidious and unpronounced varieties. This lesson alone might be deemed a sufficient result of Dr. Sansom's valuable lectures.

THE PLEA OF INSANITY IN CRIMINAL CASES.

LORD DEAS is an octogenarian Scotch judge, with a vigorous intellect, which is not one whit impaired by the weight of eighty years. Of late this worthy judge has developed certain well-marked eccentricities, prominent among which are his constant "sitting upon" counsel, his depreciation of medical testimony, and his humorous "asides" in the course of trials. It must be said of these that they are racy, sagacious, and not unfrequently witty. Whether the Bench is the place where they are seemly and appropriate it is not for us to determine. At the recent Glasgow Circuit Court a case of murder was tried, to the medical aspects of which we desire to make a cursory allusion. To every well-constituted mind it must be a matter of sincere congratulation when extenuating circumstances exist in cases of murder to save the accused from the gallows; and in what we are about to remark, we must not for a moment be supposed to write with any feeling of regret that mercy tempered justice. The facts of the case are briefly these:—George Miller, a soldier belonging to the Highland Brigade, was charged with murder. It was alleged in the indictment that, on the 30th December last, in a cell at the Southern Police Office, Glasgow, he attacked a man named Robert Frew, bricklayer, dragged him from a wooden bed, kicked him several times on the head, chest, and sides, and other parts of his person, struck him several blows with his fists on the head, face, and chest, and otherwise maltreated and abused him, by which his upper jaw and several ribs were broken, and from the effects of which he immediately died. When the deceased was taken into the police office he was so drunk that he could not walk, and the prisoner was found lying in a close before being taken to the office, and according to the statement of the constable, "he was helplessly drunk when I found him." Both men were placed in the same cell; at half-past eight "they were both lying asleep on the bed," and at ten minutes past eleven the following was the condition of matters:—The body of Frew was lying on the floor dead; the floor of the cell was covered with blood. The prisoner's hands were covered with blood. Dr. Chalmers, police surgeon, saw him shortly after this at the bar of the police office, when he "was calm and collected. He did not appear as if a serious charge was brought against him. He did not appear as if he were in drink. He appeared to be rather a person affected in his mind." At the time Dr. Chalmers thought the

prisoner insane. At the commencement of the trial the following episode occurred: "Mr. Maclellan (prisoner's counsel)—I have to ask your Lordship to permit three medical experts to examine the prisoner; Dr. Yellowlees— Lord Deas—I don't know any such practice, and I never allow it. You will suffer no injustice by that. It is not usual, and I don't give you permission. Go on, please." Addressing the Jury, his Lordship said, "No persons are better judges of whether a man is or is not insane, in the eyes of the law, than an intelligent jury. Doctors are mere witnesses. You are the jurymen and the judges." The following day, in complimenting medical witnesses from Greenock, Lord Deas again expressed his opinion of medical men in the following terms—terms certainly the reverse of flattering to the gentlemen who usually give evidence in this court:—"The gentlemen (the medical witnesses) gave their evidence in a very cautious way, and the questions that were put by the jury were all very proper. . . . The doctors had no theories to support, and he was glad to have such respectable men in the box, for *that was not always to be had.*" It would appear that in the eyes of Lord Deas the indulgence of a theory and the support of it is a disreputable thing! Turning to the case of Miller, the law in a case of insanity from drink is thus laid down by his Lordship:—"There was no doubt that if the man was insane at the time that he committed the offence, it did not matter whether the insanity lasted for half-an-hour or ten minutes, or how long it lasted, they could not find him guilty of murder if at the time he committed the assault he was insane.

. . . Merely under drink would not do; but if drink produced insanity for however short a time, and the man did certain things while insane that there was no reason to think he would do while sane, that was quite enough." *Delirium tremens*, we presume, is insanity from drink; yet, if we mistake not, Lord Deas disallowed this very contention in the case of Grainger at the Inverness Circuit Court in 1878.

In the present case his Lordship puts the question with his usual conciseness, and certainly with a leaning to mercy, towards "which he had leaned, as he hoped he always did." The question, then, for the jury to resolve was, On what data is the contention of temporary insanity based? and are they of such a nature as to carry conviction to an intelligent mind? Dr. James Chalmers testifies to having seen the man repeatedly since he committed the crime. "He seems well enough. He can speak well and intelligently enough. Constitutionally, he appears to me a cool and collected man. I saw no trace of disease of the brain about him." This is surely testimony to a physical and mental condition the reverse of insane; but Dr. Chalmers adds: "I thought his insanity might pass away in a few hours. When I saw him on Sunday he appeared to be all right. His state on Saturday night appeared to be a temporary one. In the absence of any history of the man, I think he is a person who, if he never touched drink, would be able to lead a rational life." What insanity would soon pass away? The effects of drink and the consequent violence? Beyond this, Dr. Chalmers signally fails to indicate one single feature of insanity; and truly, if

this be insanity, there are a great many insane people in Scotland, as elsewhere. Dr. Samuel J. Moore, being questioned as to his opinion as to the state of the man's mind when he committed the act, replies: "He must have been very much infuriated." Doubtless, but being so infuriated as to kick a man to death does not constitute insanity. Dr. Yellowlees, who was asked by the Procurator-Fiscal to examine the accused in prison, deposed that "he could only form an opinion as to what his condition would be in drink from what he himself told me." "Suppose I tell you that the prisoner, being in a cell in the police office, attacked another man beside him, kicked several of his ribs into fragments, broke his upper jaw, killing the man with great violence in a minute, would it consist with your opinion that that was done while he was in a condition of temporary insanity? It is possible that that might have been done under temporary insanity, and that the man afterwards might not have been aware that he had done it." It is unquestionably possible; but bare possibility is not proof, nor is savagely kicking a man to death under drink and forgetting all about it afterwards insanity, if it be not insanity to be drunk at all.

"If the prisoner said immediately afterwards that he knew nothing about it, remembered nothing about it, do you think he was speaking truthfully?—The prisoner spoke to me quite frankly about this occurrence, and about previous occasions on which he had been similarly affected. He told me that upon this, and on previous occasions, he was utterly unconscious of what had happened while he was under the influence of liquor, that liquor produced upon him the effect of being utterly unaware of what had taken place." Hitherto the evidence of insanity, according to Dr. Yellowlees, consists in a state of violence during drink, and subsequent unconsciousness of the condition. If this be insanity the law must be radically changed at once, and no small body of men will come under its operation! "The Advocate-Depute: From your study of him do you find him a man below the average as regards education and intelligence? He is below the average in both." "Did you test him about the name of the General who commanded his brigade in the Egyptian war? I did, I asked him if he remembered the one-armed General who commanded his brigade in the Egyptian war. He replied that he had seen him, but he did not know his name. That showed defective intelligence!" Doubtless; but defective intelligence is not insanity; and it is more than likely that hundreds of soldiers in the same brigade were equally ignorant as to the name of their general. The game of war is not one congenial to high and refined intelligence, and being "below the average as regards education and intelligence" may possibly make the man the better soldier. There is a true observation of Stuart Mill's that a man of fine feelings, high culture, and generous impulse will never make a successful general. Dr. Alexander Robertson stated:—"I have had an interview with the prisoner, and have carefully considered his case. I am of opinion that when he committed the act with which he is charged he was labouring under a short paroxysm of insanity." We are very much dis-

posed to think that in a certain sense every man who commits murder is "labouring under a short paroxysm of insanity," yet this does not come within the legal acceptance of the term insanity. "Might the immediately exciting cause of that attack be drink? That may have helped to aggravate the condition, but from a study of the case I am of opinion that probably it was due to an attack of a form of epilepsy." A sufficiently vague and indefinite answer in all certainty. On this evidence the man was acquitted of the capital charge. We speak with the deference due to the position, the intelligence, and the experience of the experts in this case, while we submit that we fail to recognise in the foregoing evidence the most slender proof of insanity. It is entirely made up of contingency and supposition. We are far from denying that George Miller, when he committed the horrible deed with which he was charged, was not maddened by drink; but if every man who commits a crime in this state can claim on this account an immunity from punishment, jurisprudence must be modified accordingly. We think humanity demands that every allowance should be made for perverted reason and impulse, no matter how induced; but the anomalies and inequalities of punishment are certainly perplexing. Was not the case of Guiteau one on which infinitely less doubt could exist on the question of insanity than that of Miller? A poor young lad of nineteen going peaceably home from a humble party with a few females, and other friends, is goaded into anger by the rough jests of one or two whom they encountered on their way. He seizes the first weapon at hand, which turned out to be a hoe, and struck his tormentor on the head, death resulting. That unfortunate young man expiated his crime—if indeed an act so unpremeditated and thus provoked were a crime—on the scaffold. If ever there were extenuating circumstances in a case of murder they existed in the case of Docherty.

Notes on Current Topics.

Angina Pectoris.

It is not unworthy of note that within a brief space of time two eminent and valuable lives should have been cut short under circumstances so far similar that the same cause of death, angina pectoris, has been assigned in both cases. Gustave Doré and Sir George Jessel both succumbed to this insidious and terrible disease; and almost at the same time as the latter named was seized with the fatal attack, a very highly esteemed and well-known clergyman at Sydenham, the Rev. W. Taylor Jones, died from the same affection. In our present knowledge, or rather ignorance, of angina pectoris, of its causation and its pathology, there is so much to be learnt in connection with it ere we can at all trustfully treat it for cure, that the necessity for carefully studying every fragment of suggestion bearing on it needs no expressing. Beyond the fact that it is most certainly a nervous affection, or at any rate an affection of which the symptoms depend intimately on the pneumogastric and sympathetic nerves, there is really nothing positive to guide the physician

who essays to relieve it; and he is at the best compelled to devote himself to the amelioration of symptoms in all that he does to ease the sufferer. Bristling as it is with difficulties to impede the student, it may still be hoped that recent events will bring angina pectoris once more into the prominent rank of diseases requiring to be deliberately studied in the light of every recent advance in medicine and pathology, and with the assistance of the most perfected modern methods of research.

Guardians' English.

CURIOUS and oftentimes ludicrous as the proceedings of boards of guardians frequently are, probably no other guardians ever attained such sublime heights of absurdity as those of Gainsborough at their meeting on the 20th ult. It seems that one of these local luminaries having been puzzled to understand the reports presented by the medical officers of the union—a difficulty associated presumably with certain details of a painful nature, and not remotely connected with elementary deficiencies in the way of intellectual treasures—moved, and succeeded in carrying, a resolution to require these reports to be written in language "that might be better understood." One of the medical officers to whom this startling demand was addressed not unnaturally appended a glossarial supplement to his report, which reasonable precaution against misunderstanding the exacting guardians construed into an insult worthy of "explanation." It would seem, from the discussion evoked, that Gainsborough's guardians will be happy only when their medical officers consent to write official reports in Gainsboresse, this being apparently the only language which is intelligible to at least a section of the board; for, notwithstanding abundance of "explanation," a narrow majority alone prevented the unlucky doctors from being "reported to the Local Government Board for defying the wishes of the guardians." As the matter is to be brought up again, the authorities in Parliament Street may even yet be called on to decide whether medical reports should be couched in terms more grateful to certain Gainsborough guardians' ears than the grammatical and occasionally technical English customary to be employed by medical officers of health. It may be as well to add that one of the incriminated doctors has held his post for *thirty years*, and is now, for the first time, required to write in language "that may be understood!" The Gainsborough schoolmaster is surely a long way abroad.

The Combined Colleges Scheme.

WE have much satisfaction in learning that the views we expressed last week concerning the combination of the Royal Colleges of Physicians and Surgeons in London are very generally reflected throughout the profession, and that the "scheme" is without favour among the majority of the members and Fellows of the interested institutions. What action these bodies will take in the face of the very decided opposition their arrangement has excited we are, of course, unable to say; but it might be wisely done if they forthwith decided to rescind the resolutions by which they mutually agreed to enter into a compact which is little likely to redound to the credit of either. Moreover, as the consequences which will surely

ensue from adoption of the scheme are more carefully considered, it becomes increasingly apparent that the two Royal Colleges will be the last to obtain additional advantages by imposing prohibitive restrictions on candidates for their licences. The College of Surgeons, indeed, already, if report speaks truly, sees the folly of its action, and will so far depart from the terms of the agreement as to grant its special qualification to candidates possessed of proper medical diplomas; and thus the only tangible profit the compact can secure to the unfortunate College of Physicians will be taken away, while its "double" qualification will once again sink into competition with the L.S.A., as being merely a licence in medicine. Surely it must be plain by this that the whole proceedings which terminated in the production of a "conjoint scheme" have been ill-advised, ill-carried out, and had best be consigned to the limbo of ridiculous failures.

The Case of Dr. Abrath.

THIS case, which has been several times before the Courts, came on again for hearing last week as an appeal case in the Court of Queen's Bench. It will be remembered that Dr. Abrath, of Sunderland, was the medical attendant of a person named McMann, who, in travelling by the North-Eastern Railway Company's line between Newcastle and Sunderland met with an accident, which, according to his account, was of a most serious nature, causing a long illness and serious permanent injuries. He was professionally attended by Dr. Abrath, and subsequently brought an action against the Company for damages. This was settled out of Court by the Company agreeing to pay McMann £725 as damages for his injuries and £300 as costs. Subsequently, under the belief that Dr. Abrath had healed McMann in such a manner as to make two scars on the base of his spine in order to make the injuries inflicted greater than they were in reality, the Company indicted both doctor and patient for conspiracy; but at the trial at Derby they were acquitted, and Dr. Abrath then brought the present action for malicious prosecution. It resulted in a verdict for the Company on technical grounds, and the plaintiff obtained a rule for a new trial. After hearing counsel on both sides, their lordships, Justice Grove and Justice Lopes, reserved their judgment.

The Drainage of Sheffield.

DRAINAGE in Sheffield is at present in a most unsatisfactory condition. It is altogether disgraceful in connection with a town of such importance and great natural advantages for securing a most perfect system of drains. In every direction there could be no possible difficulty in securing a fall sufficient to ensure the flow and clearance of the drain contents. Large districts are at present absolutely destitute of any proper provision for drainage. Where the sewers run to, or where the sewage is discharged, are questions to which the sanitary authorities of the town could give no very satisfactory answers. In sanitary matters, "out of sight" is but too frequently "out of mind;" and unless compelled thereto by conditions that are openly and absolutely offensive, people are hard to be moved, and show the most marked want of

interest and apathy in such questions. The very people who would be horrified to see a house in flames, and a life endangered thereby, are callous, when it is only sewer-gas that is creeping through every part of their houses, bringing with it a lowered condition of health, and inability to resist the numerous forms of disease, and intensifying the virulence of such diseases when present. They pity, of course, the long days of illness, and anxiously await the developments of the disease; but the pain and suffering is not compressed into the few short moments of agony that are experienced by those in danger from fire, and which appeals so forcibly to the sympathy of the on-looker. Could people realise properly the conditions and sufferings of disease, and the *entourage* and expenses entailed thereby, their interests in everything pertaining to sanitation and the proper preservation of health would be greatly quickened, and we would hear no more of the too-often present existing apathetic indifference. As the result of a resolution passed in the Town Council on the 1st of December, 1882, an elaborate report has been drawn up by Messrs. Charles Gott, C.E., of Bradford, and Robert Davidson, C.E., borough surveyor, accompanied by detailed plans showing the position and direction of the proposed main drains, together with plans of the necessary works at the outfall. This report is now under consideration, and has been noticed at length in the *Sheffield Daily Telegraph*, March 9th, 1883. The cost of the proposed scheme is £147,218. It is to be hoped that the men in authority in the town will show an enlightened appreciation of their responsibilities, and that they will guard against half measures being taken. Let them go at once to the root of the matter, and dispose of it once and for ever.

Presentation to Dr. Flinn.

DR. EDGAR FLINN, on the occasion of his leaving Brownhills, Staffordshire (where he had been in practice for over seven years), was presented with an illuminated address and valuable timepiece, subscribed to by the miners of the Brownhills and Conduit Collieries, numbering 2,000. The inhabitants of the district also presented him with a superior case of surgical instruments, accompanied by a beautifully-illuminated album containing an address and the names of the subscribers. Dr. Flinn, previous to his departure, was entertained at dinner at the Station Hotel, when many expressions of regret were made at his removal to Kingstown, Dublin, on his appointment as Surgeon to St. Michael's Hospital.

Presentation to Dr. MacNaughton Jones.

THE students and graduates of the Queen's College assembled last week in the examination hall, and presented Dr. Jones with a beautifully-illuminated address and an accompanying gift on his severing his connection with the College consequent on his departure from Cork. The gift consisted of a magnificent clock set in bronze. The Chairman (Mr. J. Musgrave), in opening the proceedings, said that during Dr. Jones's connection with them the links that bound professor and student in college life had been strengthened by the repeated evidences which he had given of the intense interest which he took in the welfare of the students. His efforts towards the advancement

of medical science in Cork had been crowned with abundant success, as would be quite evident to any one who looked at the hospitals with which he had been connected, some of which had been founded by him and others, and owed their independent existence entirely to his exertions. Subsequently Dr. Jones delivered a farewell lecture to the students in the College.

The annual dinner of the staff and students of the South Charitable Infirmary and County Hospital was held on March 13th, in compliment to Dr. H. Macnaughton Jones, M.D., previous to his departure for London. The chair was occupied by W. C. Townsend, Esq., M.D., senior physician; the vice-chair by E. R. Townsend, Esq., M.D., physician.

The General Medical Council

WILL meet on the 19th of April. We assume that the Medical Bill will be discussed, but it will not be the exclusive or even the chief business of the meeting, which has abundant work to perform irrespective of medical reform. The English Branch Council and the Executive Committee will meet on the previous day.

Prescribing versus Compounding.

AN action has recently been fought out in America in which a physician sought to recover damages from a chemist for having dispensed a drachm of podophyllin instead of a grain, and thereby endangered the life of a patient. The defence was that "one drachm" was the quantity ordered in the prescription; but the doctor averred that he wrote "one grain," and that an alteration had been made by the chemist to cover his mistake. The prescription was submitted for examination to two experts, who reported that no alteration had been made, and the jury returned a verdict for the defendant. Incidentally, the question was raised whether a chemist is justified in putting up a prescription ordering a dangerous excess of any ingredient, concerning which the judge ruled that, if the prescription of a regular practising physician is dispensed as written, the dispenser is not responsible.

Carbolised Iodoform.

THE following formula is given by C. Sherk (*Berliner Klin. Wochenschrift*) as a great improvement over plain iodoform:—R. Iodoform., 10 gr.; acid. carbolic., '05 gr.; ol. menth. pip., 2 drops. The acid is to be rubbed up with the iodoform, and the peppermint oil added subsequently. The disagreeable odour of the drug is completely covered, and it is not again developed even at an elevated temperature.

DR. RUTHERFORD, of Woodilee Asylum, Lenzie, near Glasgow, has been appointed Medical Superintendent of the Crichton Royal Institution, Dumfries.

PROFESSOR J. BELL PETTIGREW, M.D., F.R.S., was on Thursday last unanimously elected to the additional Examinership in Anatomy, Glasgow University. At the same Court, Dr. Andrew Wilson was elected Examiner in Botany and Zoology, and Dr. David Newman, Examiner in Physiology and Pathology.

Irish Graduates' Association.

THE annual dinner of this Association was held at the Holborn Restaurant, at 7 o'clock, on the 17th inst., Dr. Waters, of Chester, in the chair. Among those present were Sir W. MacCormac, Drs. B. Foster, Glover, Daniels, J. Thompson, W. Donovan, Fagan, Wheeler, de Gorrequer Griffith, W. E. Hart, &c. Dr. Waters proposed "The Health of the Queen and the Royal Family;" Sir W. MacCormac, "Our Guests;" Dr. Donovan, "Our next Meeting." At a Council meeting held before dinner, a form of petition was laid before the Council, and it was ordered that the President and Secretary be authorised to sign and forward it for presentation to both Houses of Parliament. The petition prayed that the Medical Act Amendment Bill now before Parliament should become law. The Council also requested the President and Secretary to take steps that might be necessary to cause the M.K.Q.C.P.I. to become a registrable diploma.

Notification of Infectious Disease.

Two deputations recently waited upon Sir Charles Dilke, one from medical officers of health and others, under the auspices of the Social Science Association, and the other from the Vigilance Association, introduced by Mr. Hopwood, M.P. The object of the former of these was to urge that the Government should give its support to Mr. Hastings's compulsory Bill; whilst the latter had attended to protest against Government interference in the matter. The interview seems to have been peculiar. At the outset Sir C. Dilke informed the Social Science deputation that there was no necessity for them to go into the question as to the necessity of compulsory notification, since, on that point, there was no difference of opinion between him and them. Sir Rutherford Alcock, who, as chairman, had forced a vote in favour of notification by refusing to hear any proposition against it, alluded to the report of the Select Committee, which showed that in twenty-three urban centres the principle of the proposed Bill had been at work with marked advantage. This is the committee which gave its decision, having refused to hear any evidence *contra*. In reply, Sir Charles Dilke said that the Government were not quite ready to adopt the Bill in its present form, for fear that, in going in advance of public opinion, such a step might produce reaction. He was of opinion that the time had not yet come to give universally the compulsory powers proposed in this Bill by absolute legislation; at the same time he would advocate the plan of giving to local authorities, who might apply, the means of dealing with infectious diseases at once, without the necessity of applying for a local Act, and this the Government was disposed to do, either by means of a general Act which they could bring into force themselves, or else by giving them power to make by-laws for that purpose. In answer to a question as to whether the Local Government Board proposed to introduce any Bill on the question, the President said the prospects of legislation this session were not promising. In receiving the second deputation Sir Charles Dilke could only be brought to observe that at present the Local Government Board had done nothing more than promote measures whereby the local representatives of the people might take their own course in regard to these matters.

Wakes in Cases of Death from Infectious Diseases.

IN reply to a question put in the House of Commons last week by Mr. W. Corbet on this subject, Mr. Trevelyan said that section 149 of the Public Health (Ireland) Act, 1878, gives powers to the Local Government Board to make regulations for the prevention of the spread of infectious diseases, and for the speedy interment of the dead only in the case of the existence or apprehension of any formidable epidemic or outbreak of such a disease. Its provisions are not applicable to ordinary cases.

The North Dublin Union Workhouse.

THE Inspector of the Local Government Board for Ireland, Dr. MacCabe, has reported most unfavourably on the sanitary condition of this institution. In his half-yearly report, dated February 16th, 1883, he says that during the past six months nearly every department had been overcrowded. The nominal accommodation, according to his calculation, is about 2,079; according to the estimate of the *Guardians*, it amounts to 2,513. On January 25th the inmates numbered 2,668. During the six months embraced in the report (July 1st to December 31st, 1882) the average daily number was 2,484. He observes that in the present overcrowded state of the workhouse the introduction of a single case of typhus to any of the wards in the main buildings may be attended with disastrous consequences.

Royal Institution.

THE following are amongst the arrangements for the lectures after Easter:—Professor J. G. McKendrick, ten lectures on "Physiological Discovery;" Professor Tyndall, three lectures on "Count Rumford, Originator of the Royal Institution;" Mr. R. J. Poole, three lectures on "Recent Discoveries in (1) Egypt, (2) Chaldæa and Assyria, (3) Cyprus and Asia Minor;" Mr. A. Geikie, six lectures on "Geographical Evolution." The discourses on the Friday evenings will probably be given by Mr. A. Geikie, Dr. Waldstein, Professor B. Balfour, Mr. C. W. Siemens, Mr. R. A. Scott, and Professors Huxley, Turner, Flower, Pollock, and Dewar.

Victoria University—another Licensing Body.

THE *Manchester Times* says "that the signature of the Crown has been affixed to a supplementary charter empowering this institution to confer degrees in medicine."

PROFESSOR VON BRUNS has just died at Tubingen.

SIR WILLIAM JENNER, Bart., was on Monday, 19th inst., almost unanimously re-elected President of the Royal College of Physicians.

A REPRINT from the *American Journal of the Medical Sciences* reaches us which contains an article by Dr. Atlee on "Strangulated Hernia;" another by his son, Walter F. Atlee, on "A Case of Ovariectomy;" and another by his grandson, Louis W. Atlee, on "A Case of Congenital Cyst of the Back of the Head."

MR. HERBERT SPENCER, F.R.S., has declined to be put in nomination for the post of Lord Rector of St. Andrews University on account of ill-health.

PROFESSOR SAYRE, of New York, is better, and has returned to his professional duties. Dr. Van Buren, who is suffering from hemiplegia, continues in a very critical state.

DR. P. MACBRIDE, Lecturer on Diseases of the Ear in the Edinburgh School of Medicine, has been appointed to the post of Aurist and Laryngologist to the Edinburgh Royal Infirmary.

H.R.H. THE DUKE OF CONNAUGHT has signified his intention of taking the chair at the anniversary festival dinner of the Metropolitan Free Hospital, the funds of which are in a very low condition.

WE understand that the vacancy caused by the resignation of Dr. Braxton Hicks, Obstetric Physician to Guy's Hospital, has been filled by the appointment of Dr. Galabin, who is succeeded as Assistant Obstetric Physician by Dr. Horrocks.

AS evidence of the healthiness of London it may be mentioned that last week, of its four millions of inhabitants, there was not a single death from typhoid or from simple cholera, and but one from small-pox; the corrected mortality from all causes being sixty-five under the average of the past ten years.

A PRACTICAL demonstration of a means of purifying the Underground Railway by Dr. Neale's "Chemical Lung," without the aid of unsightly and unhealthy shafts, as also the best means of cooling and purifying sick and crowded rooms, law courts, &c., is announced to be given at No. 77 Church Street, Lisson Grove, Marylebone, on Thursday, the 29th inst., at 8.30 p.m.

WE understand that Dr. James Little has resigned the Professorship of Practice of Medicine in the School of the Royal College of Surgeons in Ireland. Dr. Little has met with equal success as a teacher and a practitioner, and his retirement from teaching will be a serious loss to the College School, where his prelections have been thronged by students. Dr. John William Moore, Lecturer on Medicine in the Carmichael School, has delivered the lectures of Dr. Little's course for the last two months, and he will probably be a candidate for the vacant chair. The College Council has not yet decided when the election of a new Professor will take place.

OWING to the prevalence of cold east and north-east winds during the past week, the death-rate has risen sensibly throughout the United Kingdom, notably in the northern districts. Last week the annual rates of mortality in the principal large towns, per 1,000 of their population, were:—Portsmouth, Salford, Derby 18, Brighton, Huddersfield 19, Bradford 21, Cardiff, Wolverhampton 22, Edinburgh 23, Bristol, Birkenhead, London, Leicester, Halifax 24, Leeds, Blackburn, Birmingham, Sunderland 25, Bolton, Sheffield 27, Newcastle-on-Tyne, Hull 28, Oldham, Norwich, Plymouth 30, Glasgow 33, Liverpool, Manchester 34, Dublin, Nottingham 35, Preston 37.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

EDINBURGH HEALTH SOCIETY.—We have to congratulate the above society on its sound financial position, and on its increased activity in the cause of sanitary science and the improvement of the general health of the citizens of Edinburgh. In a late issue we felt called upon to make some remarks on the work done by the society, for although we had heard much of the "objects" of the society, we had failed to discover any effort made for the benefit of the people beyond the delivery of lectures. We have no wish to detract from the merit and importance of the lectures that have been delivered, but we wished to see precept and practice go hand-in-hand, and also to avert the tendency of such societies to become the mere instrument of a clique. We therefore learn with pleasure from the remarks of the chairman made at the annual meeting held last week that active measures are to be taken with regard to certain sanitary questions which are now exercising the mind of the citizens, and we hope that at the next annual meeting we may be able to congratulate the society on the practical work done.

THE EDINBURGH UNIVERSITY BUILDINGS COMPLETION FUND.—Strenuous efforts are being made to collect sufficient funds to complete the University Medical School buildings, so as to have them ready in time for the centenary commemoration of the University next April twelvemonth. The sum required is about £80,000, and to this several large sums have already been subscribed. It is to be hoped that the efforts of the committee will be liberally supported, and that the completion of the buildings will be accomplished before the end of the present year. Graduates in all parts of the world have now an opportunity of showing in a substantial manner their regard for their *alumni mater*. The Town Council, at the instance of the Lord Provost, have granted a sum of £1,000 towards the fund, which is actively supported by Lord Provost Harrison.

GLASGOW OPHTHALMIC INSTITUTION.—The fourteenth annual meeting of this institution was held on the 13th inst., when the report showed that there had been a decrease of 75 out-door, and an increase of 59 in-door, patients, as compared with the previous year. The average period of each patient's residence in the house was 21.1 days. 674 operations had been performed. During the past year 252 workshops had contributed towards the support of the institution, and the income had amounted to £1,140 5s. 2d. The report was adopted on the motion of the chairman, seconded by Provost Browne, and various other resolutions being passed, including one of thanks to the donors and subscribers to the institution, and the medical staff, the proceedings terminated.

GLASGOW.—HEALTH OF THE CITY.—From Dr. Russell's report for the past fortnight it would appear that there were 609 deaths registered, as compared with 590 in the fortnight preceding, an increase of 19, representing a death-rate of 31 per 1,000 living in place of 30. In the corresponding fortnight of last year the death-rate was $6\frac{1}{2}$ per 1,000 less. There were 119 more deaths in this fortnight, which are composed of an increase of 35 in miscellaneous unclassified diseases, of 33 in zymotic diseases, of 32 in diseases of the lungs, and 19 in diseases affecting the nervous and digestive organs in young children, so that the past fortnight has been one of general ill-health, as well as of special fatality from the prevalence of zymotic diseases—especially whooping-cough and scarlet fever. The number of deaths from infectious diseases of children was 77 in place of 67—viz. 46

from whooping-cough, 17 from scarlet fever, and 14 from measles. Although there is no substantial diminution in the mortality of whooping-cough for the fortnight, as already stated, there were only 14 deaths last week—the lowest for several months. The average age of the 46 fatal cases was 21½ months. The deaths for the week ending with Saturday, the 17th inst., were at the rate of 34 per 1,000 per annum, as compared with 31 for the preceding week, and 25, 30, and 28 for the corresponding weeks in 1882, 1881, and 1880.

EDINBURGH.—HEALTH OF THE CITY.—For the week ending with Saturday, the 10th inst., the mortality in Edinburgh was 83, and the death-rate 19 per 1,000. There were 13 deaths under 1 year and 24 above 60, of which 3 were above 80 years. Diseases of the chest accounted for 40 deaths, and zymotic causes for 9, of which 3 were due to fever, 1 to diphtheria, and 2 to scarlatina. The intimations of these diseases for the week were 8, 4, and 11 respectively. For the week ending with Saturday, the 17th inst., the mortality was 101, and the death-rate 23 per 1,000. Diseases of the chest accounted for 55 cases, and zymotic causes for 10, of which 3 were due to fever, 1 to diphtheria, and 1 to measles, the intimations of these diseases for the week being 8, 7, and 7.

THE EXTRA-MURAL SCHOOL, EDINBURGH.—We learn that there is some prospect of this school being placed on a better footing than it has enjoyed for many years. A requisition is to be presented to the colleges signed by the lecturers, and rumour states that the demands of the school are likely to be favourably received by the College of Physicians. The College by requiring an examination for its membership, and by other acts has shown of late a considerable desire to meet the wishes of the profession, and it is to be hoped that wise counsels will prevail and that something will be done for the Extra-Mural Medical School.

THE UNIVERSITY EXAMINATIONS.—The Chancellor of the University has given his permission to the alteration of the law with regard to the admission of candidates for the first examination, and all that now remains is Her Majesty's approval of the proposed new regulation. Students will then be able to go up for the first examination at a much earlier date than formerly, and we may thus hope that, as there will be less time for idleness, there will be fewer rejections.

SUICIDE OF A MEDICAL GENTLEMAN.—Early on Friday last, Dr. Edward Touch was found dead in his lodgings in Main Street, Inverary. The deceased was found lying across the bed with his throat cut. He was observed to suffer from mental depression for some days, but nothing serious was apprehended. Dr. Touch served with distinction for many years in India, and began his medical career in the 92nd Regiment. He was well known and much respected by Indian officers. About nine years ago he came to Inverary, where he gained a good practice, and was a favourite in town and country, not only on account of his professional skill, but for his kind and gentlemanly disposition. He also held the appointment of Surgeon of Her Majesty's Prison of Inverary, and his melancholy end has caused a profound sensation throughout the district. The deceased has left a widow and large family, who reside in Dunoon, the majority of the children being young.

EDINBURGH UNIVERSITY COURT.—At a meeting of the Edinburgh University Court, held on Tuesday, the 20th inst., among other business there was laid before the Court a copy of the proposed alterations of the ordinance 22, section 9, applicable to the University of Glasgow only, which had been received from the Council Office for observation, and in connection therewith there was submitted a relative minute of the Edinburgh Senatus. It was resolved to intimate to

the Lord President of the Council that the Court saw no objection in point of form, as they did not seem to effect the object of their being applicable to the University of Glasgow only. There was laid before the Court a copy of the proposed alteration of ordinance No. 22, Glasgow No. 4, relating to the fees for graduation in medicine in the University of Glasgow, which had been received from the Council Office for observation, and in connection therewith there was submitted a relative minute of the Edinburgh Senatus. It was resolved to intimate to the Lord President of the Council that the Court saw no objection to the proposed alteration. On consideration of a minute of the Senatus, a vote of £2,000 from the General University Fund for the completion of the new University buildings was approved of.

GLASGOW UNIVERSITY. — LORD RECTOR. — The Right Honourable John Bright was, on Thursday, the 22nd inst., installed as Lord Rector of the University of Glasgow in St. Andrews Hall, the Very Rev. Principal Caird presiding. There was nothing very striking either in the address or in its mode of delivery. It was mainly an *apologia pro sua vita*. Much credit is due to the students for their exemplary conduct throughout the entire proceedings.

DUMFRIES. — MEDICAL SUPERINTENDENTSHIP OF THE CRICHTON ROYAL INSTITUTION. — Dr. James Rutherford, of the Woodilee Asylum, Lenzie, has been appointed Medical Superintendent of the Crichton Royal Institution and Southern Counties Asylum, Dumfries. Dr. Rutherford was formerly Superintendent of the Argyllshire Asylum, and was elected Superintendent of the Lenzie Institution in 1874. He occupies a high position in the department of Psychological Medicine, and in conjunction with Dr. Lockhart Robertson, is the translator from the German of Griesinger's well-known book on mental diseases, which was printed by the New Sydenham Society in 1867, and has since become a standard text-book.

Correspondence.

MERCANTILE MARINE MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR, — Feeling much interested in the mercantile marine medical service, I have for some time past read with great pleasure the different correspondences which have appeared in the various medical periodicals in England and Ireland, bearing on this all important subject. As you have, Sir, with your usual ability, entered *con amore*, into the matter, I trust you will permit me to make some observations. The first great step in the securing of competent and reliable medical men must be made by the payment of an adequate salary. At present, I regret to say, the salary the medical officer receives is, in most cases, on a footing with that given to the stewards, carpenters and other petty officers, therefore, the surgeon is obliged to resort to the most lowering and objectionable practice of accepting gratuities and presents from the passengers; again, by these acts, bringing himself on a par with such men as the steward, who, of course, receives his "tips." As it occurs that in some instances the ship's surgeon is a gentleman (which I regret to say is not always the case), he sees the acceptance of these "tips" in their true and derogatory light, degrading in the most obvious manner to their professional and authoritative (?) position on board. Hence, the man who does not push himself forward to receive these "gratuities," often finds himself, at the end of a voyage, a poorer man than when he sailed. Why is this? Because his salary, as I have said, is most shockingly low, generally £10 or £8 per month. Many of the passengers insist during the voyage on "standing" champagne and other expensive wines to the doctor, who generally, either at the saloon-table, or in the smoke-room, makes himself prominent. Of course, by the laws of etiquette, he has to return these hospitable recognitions! In former times the doctor, in

addition to good pay, received "wine money;" now he has to pay the full price. So, since 1856 the doctor's expenses on board have greatly increased, and his duties, as we all know, has increased tenfold. Hence we see that the ship owners have not only added to expenditure, heaped various hardships, indignities, and extra duties on his shoulders, but have to an equal extent, cut down his salary. Let the authorities demand of ships' surgeons some higher qualification than that of "physician, surgeon, or apothecary." Let them see, and demand, that he receives a proper and adequate remuneration, which will prevent the necessity of accepting "tips." Let them secure for the medical officers on board a position of authority on all sanitary matters. And last, but not least, let them see that his quarters are those suited to the habits and customs of a gentleman; not a cell lined round with physic bottles, and being scarce 5 feet 8 by 6! May I ask, Sir, where the difference lies as regards the lives of passengers and sailors on board vessels in the mercantile service, and those in the royal navy, where every provision is made for comfortable quarters, in accordance with the position of the medical officers; and also a proper surgery fitted up regardless of expense, and furnished with every medical comfort? When these things have been considered, and their enactment enforced, the offices of transatlantic and other shipping companies will no longer be infested by the chronic tipplers and idlers, who are too often secured, for small payment and temporary lodgings, to look after the many requirements of some hundreds of souls, confined, as is too often the case, in badly ventilated and unsanitary steamers.

This is a subject which I assure you requires the gravest consideration of Her Majesty's Government, and also the serious attention of the legislature of the country.

I am, &c.,

LOUIS FITZPATRICK, L.R.C.S. and Ph.R.,
Formerly Med. Officer on board one of the
Atlantic Mail Steamers.

Mitchelstown, March 9, 1883.

THE PROPOSED TESTIMONIAL TO DR. JACOB.

DR. JACOB has addressed the following letter to the Editor of the *British Medical Journal*.

SIR, — It has recently been suggested in your columns, as well as by direct communications with myself, that the profession—especially the Poor-law medical officers of Ireland—should offer to me some substantial expression of their appreciation of the services which, in years past, I have been able to render in defence of their interests. I have, hitherto, thought it best to abstain from public notice of this very kind suggestion; but, as it is again renewed, I feel that I ought to interpose before further action is taken.

I am greatly gratified with the assurances which I have received that my public work is considered worthy of recognition; and this appreciation of my humble efforts is an encouragement to perseverance, for which I warmly thank those who have spoken so kindly of me; but I must, nevertheless, deprecate (at least for the present) any further movement in the direction of a testimonial to me. I feel that I have not yet legitimately earned the esteem or gratitude of my profession, and that my work in their behalf is not yet nearly complete. If I should be able to continue, for some years to come, to do battle for their rights as public servants, and to labour with success toward raising the educational and social status of the profession in Ireland, I may, some day, hope to deserve thanks of my brethren; but, as yet, I am too young, both in years and in service, for any public recognition of my work.

The success of the movement for securing adequate pensions for Poor-law medical officers, to which I have gladly devoted myself, is, I am glad to think, not far distant; and I have every hope that other objects, almost as important, for which my co-agitators have worked with me in years past, are likely to follow. Until the campaign is over, it is too soon to think of rewards.

Yours, &c.,

ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

23 Ely Place, Dublin, February 28th, 1883.

TAPPING THE BLADDER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Apropos of M. Picard's investigations with regard to hypogastric tapping of the bladder, I beg to submit the notes of a case which will bear out his conclusion concerning the danger of phlegmonous abscess, and will, I think, illustrate another defect in the operation, namely, the impossibility of draining the *bas fond*.

January 1st, 1882.—Called in by Dr. A., to a case of prostatic obstruction in which catheterism had been attempted without success; succeeded in passing a No. 9 gum-elastic. Sent for again same evening, and failed after trying three kinds of instrument. Called Dr. B. to my assistance, who also failed, suggesting the existence of a false passage.

2nd.—Catheterism again failed. Bladder tapped with aspirator three days in succession.

5th.—Tapped with long curved trocar and cannula. Tied in cannula. Hoped that by this means patient might, by withdrawing stopper of cannula, empty bladder himself. This hope failed, as cannula gradually worked out of bladder. Signs of abscess showing themselves, hard flag, redness, pain—patient was removed to Kilkenny Infirmary, where Dr. Johnson succeeded in passing a No. 12, a Condé. The residuary urine evacuated from the *bas fond* which could not be reached by the trocar or aspirator was found to be very fetid and decomposed. Catheter tied in, but had to be withdrawn soon.

Signs of suppuration subsided. Extreme difficulty of catheterism persisting, the patient (aged 73) was worn out, and died within a fortnight after admission to infirmary.

I am, &c.,

THOMAS E. CAHILL.

ARMY MEDICAL EXAMINATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the subject of the Army medical examination is at present attracting that attention which is the natural result of recent competitions, I trust you will insert the following remarks:—

In the first place, I would insist that each candidate be given a number, and that, during the entire course of the examination, he be known by *number* only to his examiners, and *not* by *name*, as has hitherto been the case. To the adoption of such a course there could possibly be but one objection, which is too obvious to require further elucidation!

Secondly, I would suggest that unsuccessful candidates be furnished with the marks they have obtained in each subject, so that they may be aware of their deficiency, as well as of the standard according to which the marks are adjudged. This course is generally adopted at Civil Service examinations, and is also followed with regard to candidates for the Indian Medical Department. What possible objection in extending it to candidates for the A.M.D.? Mr. Gibson, having asked recently in the House of Commons if any of the examiners possessed Irish qualifications, was very plausibly, but truthfully, answered in the affirmative. Allow me just a word of explanation on this point. The gentleman referred to examines in *materia medica*, and has only 100 marks at his disposal, whilst each of the other three examiners—not possessed of Irish qualifications—examine respectively in anatomy, surgery, and medicine, to each of which subjects 1,000 marks are awarded. *Verbum sap.*

I am, Sir, yours, &c.,

ONE QUALIFIED, BUT NOT APPOINTED.

March 15th, 1883.

Literature.

AN INVESTIGATION INTO THE MICROSCOPIC ANATOMY OF INTERSTITIAL NEPHRITIS. (a)

We confess to having too long denied ourselves the pleasure of a perusal of this valuable monograph. It consti-

(a) "An Investigation into the Microscopic Anatomy of Interstitial Nephritis." By Bryan Charles Waller, M.D., F.R.C.S.Ed. Edinburgh: E. and S. Livingstone. London: Baillière, Tindal, and Cox.

tutes one of the gold medal theses for the degree of M.D. in the University of Edinburgh, and if patient microscopic investigation, a profound knowledge of the subject, and acute reasoning count for anything, the work in question seems to us to have been well worthy of the distinction conferred on its author. After a short introductory chapter, Dr. Waller devotes Chapter II. to "The Methods of Preservation, Preparation, Staining and Mounting of Specimens." To any one engaged in microscopic mounting the chapter will well repay perusal. Some valuable formulæ are given for staining solutions. Chapter III. is devoted to "Certain Points relating to the Histology of the Normal Kidney," a knowledge of which is of course absolutely essential to the proper interpretation of abnormal conditions. A "Historical Résumé" of the subject comprises Chapter IV. With Chapter V., "On Granulation Tissue, with reference to the Nuclear Tissue of Interstitial Nephritis," the controversial part of the work may be said to begin. Dr. Waller, and in this we entirely agree with him, maintains that a pre-existing inflammatory state exists in all cases of interstitial nephritis. The following passage summarises the basis of his thesis:—

"When interstitial inflammation supervenes in the kidney, an emigration of leucocytes takes place from the vessels into the lacunar system of Ludwig. The inflammation being of a formative character, these leucocytes give rise (either alone, or probably in conjunction with the fixed corpuscles, which by their division may take some part in the process) to embryonic, indifferent, or granulation cells, which after a time assume the type of more or less fibrillated connective tissue. The nucleus becomes oval, the cell elongates, takes on a lanceolate or fusiform shape, and presently fibrillation occurs, leading to the development of a greater or less amount of wavy fibrous tissue. This fibrillation can be traced from stage to stage, and is identical with the transformation of the round cells of cicatricial tissue, so identical, indeed, that the nature of the round cell tissue in the kidney is a matter, not of conjecture, but almost of absolute inferential certainty." This view is entirely in accord with the unity of pathological processes, and is supported by analogy no less than by direct observation. Dr. Waller does not say whence these leucocytes are derived, or to what special portion of the blood they belong. Is it not possible that they are *fibro-plastic* cells, and that they *do not* emigrate from the blood as such? This would be in harmony with the analogy on which Dr. Waller so justly insists. The first stage, then, of interstitial nephritis is one of enlargement, and not wasting and disintegration. In Chapter V. the "Author's own Views" are given. They are very much in accord with those of Charcot and others. Dr. Grainger Stewart's opinions are, we think, very successfully combated, no less than those of Dr. Johnson, both in this and the following chapter. The celebrated "Capillary Fibrosis" doctrine of Sir William Gull and Dr. Sutton is cleverly demolished in chapter VIII; and the book concludes with a "Note on Glomerular Nephritis." It were difficult, without entailing more space than we can afford, to enter more fully on the merits of this work. We have derived great pleasure, and no little instruction, from its perusal. We believe the author's opinions to be mainly correct, and the accompanying drawings are clear, and of excellent execution. We have, therefore, unfeigned pleasure and confidence in recommending a perusal of the work. The author will allow us to add, in conclusion, that the value of the book would not be one whit diminished by the omission of his clever jokes and occasional digressions.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing

attention to these are requested kindly to mark the newspapers when sending them to the Editor.

THERAPEUTIST.—The revised edition of the American Pharmacopœia, just issued, directs that the strength of official opium shall be greatly increased, although by some strange oversight the changes in the formulae in which this drug is employed are relatively very small. The instructions also, as to the preparation of fluid and powdered opium are by no means reliable, and might, if rigorously followed, result in serious consequences in compounding.

EPIDERMIS.—We believe Prof. Marshall, F.R.S., of University College Hospital, was the first (in 1872) to recommend epidermic medication with an oleate of mercury.

DE ARTEBUS.—The "recommendations" of the Council possess no legal importance, nor is it incumbent on any corporation to act in accordance with them, unless they prove to be acceptable. In order to enforce the regulations laid down, the aid of the Privy Council has to be invoked. The Registrar, Mr. Miller, is always willing to afford whatever information he can to *bond fide* inquirers. You might, perhaps, apply to him.

BACILLUS MOUNTING.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—In reply to your correspondent, the best method of preparing tubercular bacilli is as follows:—Take a button of phthialic expectorant in an advanced case—the first expectoration in the morning is the best; pour upon it a few drops of liquor potassæ, and work it with a glass-rod until it becomes a homogeneous fluid. Put a drop of this fluid upon a microscopic cover-glass, from 1/100 to 1/400 thick, and allow it to dry. Now pass it lightly through the flame of a spirit-lamp, filter upon it a few drops of magenta aniline solution, and let it lie for twenty minutes. Place it in a mixture of one-third nitric acid and two-thirds of distilled water until it bleaches, which will take about five minutes, and wash it with water. Next drop upon it a little methyl blue solution, and let it stand for five minutes; and finally get rid of all aqueous fluid by dipping it in absolute alcohol. To mount it, put a small drop of Canada balsam and benzine upon a glass microscopic slide, and put the cover-glass on it with the bacillus surface immersed in the balsam. This will soon harden, and will preserve the preparation indefinitely. The plan depends upon the fact that once the bacilli are stained red they cannot be decolourised by the nitric acid, which bleaches everything else; it is much facilitated and hastened by doing it at a warm temperature. By this method the bacilli are seen scarlet, and the other elements of the sputa blue. The bacillus is about one-third the size of a red blood corpuscle, and requires a power of at least 500 to exhibit it satisfactorily. The process is delicate and a little tedious; and from my own laboratory experience of it, I doubt if it will become a clinical test in general practice. The solutions can be obtained from F. Becker and Co., 84 Maiden Lane, Covent Garden, London, W.C.

Yours, &c.,
F. J. B. QUINLAN.

DR. OGILVIE WILL (Aberdeen) is thanked for his note.

ARTEMUS should write to the Rational Dress Reform Association; the matter is not in our line, although none more than medical men strongly condemn the absurdities and dangers of tight-lacing. Our columns are not supposed to reach those his letter is intended to benefit.

INQUIRER.—Our remarks were founded upon an article in the *New York Times*. The incubator attributed to Tarnier, of Paris, is not a new idea, and allowances must be made for American extravagances of diction; still, there is something in the principle, although we are not inclined to regard the supposed experiments seriously.

SHIP'S SURGEONS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—Having recently held an appointment as "ship's surgeon" in a Transatlantic steam ship I read your article of March 7th with some interest.

Complaints have been made of the youth and inexperience of the medical officers to be found on board of our mercantile marine. But how can it be otherwise, when our medical education costs at least seven hundred or a thousand pounds after leaving school, and, not unnaturally, we look for some return on the outlay. Almost the highest pay in the mercantile service for a medical officer is eight pounds a month; many get less, and very many go for nothing at all. Is it likely that any man with a desire to rise in his profession, or to make even a comfortable competency for himself, will rest content with the meagre pay of ninety-six pounds a year?

Until, as you reasonably put it, the minimum pay of ship surgeons be fixed at £300 a year, youth, inexperience, and even unqualified practice will continue to be the result if men are of the way of thinking of

Yours obediently,
A DISGUSTED SHIP'S SURGEON.

DISSATISFIED.—The matter has already received sufficient notice.

DR. WHITE.—We have not any personal knowledge of its efficacy. The note was, as stated at the time, quoted from an American contemporary, and presumably it had been communicated by a writer who was conversant with the properties of the substance he recommended. Such a shop as you refer to may be found in London without any difficulty. Consult a trade directory.

A. J. R.—The following prescription may be found serviceable:—

℞ Ammoniac sesquicarb., gr. x;
Tinct. scillæ, ℥ss.;
Decoct. senegæ, ℥viij.

One ounce every six hours.

DR. COLLINS.—The cases are interesting, and shall appear in an early number. The promised continuation will be acceptable.

VACCINATION INQUIRY.—We are asked to state that the next committee meeting will be held in the Council Room, Exeter Hall, Strand, W.C., on Thursday, the 2nd inst., at 3 p.m.

DR. K. S.—The invitation was extended to any one who might be willing to lend assistance in the matter. Hitherto but a very few have responded to it; and your suggestion, therefore, comes most

opportune. Acting on it, we have requested the gentleman named to communicate the particulars, by and of which a complete account may be prepared.

H. CROSER.—The better plan is to avoid the use of stimulants entirely until such time as they may prove to be absolutely necessary to save life. As a rule they undoubtedly are not required during the treatment even of fevers; and oftentimes they are eminently hurtful to the patient. Enlightened experience would certainly oppose the wholesale prescription you seem to have been indulging in.

MEETINGS OF THE SOCIETIES.

WEDNESDAY, MARCH 28TH.

EDINBURGH OBSTETRICAL SOCIETY.—8 p.m., Prof. Simpson, On Superinvolution of the Uterus.—Prof. Freund, Strasburg (communicated by Prof. Simpson), On Extra-uterine Pregnancy.—Dr. J. Milne Chapman, On a Case of Double Ovariotomy: Unusually Long and Twisted Pedicle.—Dr. Neil Macleod, Shanghai, On Antiseptic Midwifery.

HUTERIAN SOCIETY.—8 p.m., Mr. Rivington, On a Case of Removal of Loose Cartilage from the Knee-joint.—Mr. Charters J. Symonds, On the Use of Martin's Bandage in the Treatment of Synovitis, and a Case of peculiar Eruption on Sole of Foot, probably due to Congenital Syphilis.—Dr. Port, On a Case of Mediastinal Tumour.

FRIDAY, MARCH 30TH.

CLINICAL SOCIETY OF LONDON.—8.30 p.m., Mr. R. W. Parker, On a Case of Contused Wound of the Thigh and Leg; Gangrene of the Limb; Death.—Mr. Spencer Watson, On a Case of Tetanus.—Mr. Howard Marsh, On a Case of Tetanus following Laceration of the Toes, and persisting forty days; Recovery after Syme's Amputation.—Mr. Barwell, On the Removal of large portions of the Upper Lip, without Deformity of the Face.—Mr. H. Marsh will exhibit a Case of Ostitis Deformans.

ACADEMY OF MEDICINE IN IRELAND.—Obstetrical Section.—Specimen exhibited by Card: Dr. Macan, An Example of Fetal Rickets.—Papers: Dr. R. Henry, On the Importance of the Third Stage of Labour.—Rev. Dr. Houghton (for Surgeon William C. Ashe, B.A.), A remarkable case of Protrusion of the Uterus from Ovarian Disease in a Cingalese woman near Kandy.—Dr. T. More Madden, On some of the Nervous and Mental Diseases peculiar to Women.

TUESDAY, APRIL 3RD.

ROYAL INSTITUTION.—8 p.m., Professor McKendrick, On Physiological Discovery.

THURSDAY, APRIL 5TH.

HARVEIAN SOCIETY OF LONDON.—8.30 p.m., Patient to be exhibited with Double Congenital Dislocation of the Radius, by Dr. S. Phillips.—Pathological Specimens: Tubercular Ulceration of the Bladder, Prostate, &c., Dr. Silcock.—General Dilatation of the Ventricular Cavity in the Brain of a Lunatic, Mr. J. E. Lane.—Paper: Antiseptics in Midwifery in Lying-in Hospitals and Private Practice, Dr. John Williams.

Vacancies.

Birmingham and Midland Counties Orthopaedic and Spinal Hospital.—Assistant Physician. Applications to be addressed to the Medical Committee not later than April 8th.

Charing Cross Hospital.—Assistant Physician and Assistant Physician-Archdeacon. Applications to be addressed to the Medical Committee on or before March 31st.

Kingsbridge Union.—Medical Officer of Health. Salary, £100. Applications to be sent to the Clerk before April 6th.

Warwick County Lunatic Asylum.—Assistant Medical Officer. Salary, £120, with board and lodging. Applications to be sent to the Superintendent as soon as possible.

Appointments.

ANDERSON, E., M.D., L.R.C.S. Ed., Medical Officer to the Cramlington District of the Tyne-mouth Union.

HORROCKS, F., M.D. Lond., M.R.C.P., Assistant Obstetric Physician to Guy's Hospital.

MURRAY, H. M., M.B. Lond., Medical Registrar to the Charing Cross Hospital.

ORFORD, J., M.R.C.S., L.R.C.P. Lond., Senior House-Surgeon to the Metropolitan Free Hospital.

PETTERREW, B., F.R.S., Examiner in Anatomy in the University of Glasgow.

POWER, C. F., M.R.C.S., L.R.C.P. Lond., M.B. Camb., Assistant House-Surgeon to the Metropolitan Free Hospital.

RUTHERFORD, Dr., Medical Superintendent of the Crichton Royal Institution, Dumfries.

Births.

JALLAND.—March 18th, at St. Leonard's House, York, the wife of W. H. Jalland, F.R.C.S., of a son.

LITHGOW.—March 15th, at Stirling House, Farnborough, Hants, the wife of T. G. Lithgow, L.R.C.P. Lond., of a son.

Deaths.

ARNOTT.—March 14th, at St. Stephen's Crescent, Westbourne Park, W., James Arnott, M.D., formerly of St. Helena, aged 86.

BUNTING.—March 16th, suddenly, at Newport, Mon., Robert Bunting, L.F.F.S. Glas.

CABHILL.—March 20th, at 42B Great Brunswick Street, Dublin, David Cabhill, M.B. M.Ch., T.C.D., aged 55.

FALL.—March 15th, at Kneighton House, Winfrith, Dorset, Joseph Fall, M.R.C.S., formerly of Tollerton, Yorkshires, aged 42.

HENDERSON.—March 15th, at the residence of his son-in-law, Lewisham, Thos. Henderson, late of Edinburgh, aged 77.

HOLMAN.—March 14th, at Caverham Road, Kentish Town, Andrew Holman, L.S.A. Lond., late of John Street, E.C., aged 87.

The Gulstonian Lectures

ON

STERILITY IN WOMAN.

Delivered in the Royal College of Physicians, London,
February, 1883.

By J. MATTHEWS DUNCAN, M.D., F.R.C.P.L.,
Physician-Accoucheur and Lecturer on Midwifery at
St. Bartholomew's Hospital, &c.

LECTURE II.—PART IV.

ITS THEORY OR CAUSATION.

EXCLUDING some remarks as to the influence of marriage in causing sterility in woman, we have shown chiefly the influence of age in its production. Marking out by statistical evidence certain ages as peculiarly affected with sterility, we find at these same ages, in a proportion above the average, excessive families, pluriparity, weakly or idiotic children, &c., and not only in exaggerated proportion, but combined one with another. It is therefore reasonable to describe the sterile ages as ages of imperfect reproduction, and to associate or identify with sterility the conditions of excessive production, pluriparity, &c., which are demonstrated to have alliance with it. In other words, sterility, excessive families, and pluriparity are alternatives one of another, and almost certainly own the same general causes.

I know no cause of sterility or of its allies, excessive production, pluriparity, abortion, &c., that can be compared with age in extent and power. In discussing the cure of sterility, I shall allude to various minor causes which may operate in individual cases, but have no extensive influence. But there are causes which probably have a great place in the production of this condition whose action is only believed, not demonstrated. Such are bad general health, cold, and heat. The influence of bad general health is well observed in plants, but I know no good evidence of it in woman other than the testimony of medical practitioners. The influence of cold and of heat on sterility has been much studied, and attempts have been made to get additional

light on the matter by collecting observations of their influence on the age of commencement and cessation of menstruation. The subject divides itself into two portions: first, the influence of cold and heat on women breeding in their native lands; second, the same influence as exerted on women born in cold climates and transported to hot, or born in hot climates and transported to cold. But the data obtained are, in my opinion, quite insufficient for any reasoning being securely based. The hearsay evidence also requires scrutiny. We often hear, for example, of a girl, say of eleven, bearing a child in India, and this is held as proof of early fecundity there. We rarely hear of the same occurrence in this country; and the reason of this alleged greater frequency in India may be not earlier fecundity there, but earlier exposure of a large number of girls to the risk of becoming pregnant.

There are several important subjects, more or less closely bearing on our inquiry, which I pass by with mention only. Among these is the influence of cold and of heat on the commencement and stoppage of menstruation, an influence regarding which it is scarcely, by the statistical evidence, made probable that cold retards the appearance and hastens the stoppage, though many considerations support this view. Another is the generally accredited influence of nursing in delaying the return of menstruation and the recurrence of pregnancy. Regarding these matters, Robertson has made valuable remarks, and collected many, though insufficient, observations. The great subject of interbreeding in its production of sterility I also pass over. The evidence regarding it is very bulky, and requires most careful sifting. In plants and animals the demonstration of this injurious influence of interbreeding in producing imperfection of offspring and sterility is copiously illustrated, and may be said to be well made out; but it is not so in the case of man. Yet, in the case of man, there is a most extensive, though not universal, consensus of intelligent opinion that interbreeding has the same general influence as in plants and animals, and to the entertainment of this view the strong analogy of plants and animals lends powerful encouragement. The injurious influence in man, indeed, probably acts after birth, for there is accumulating evidence that peculiar diseases, specially of the eyes, affect, by preference, the offspring of near relations.

"The evil consequences," says Darwin, "of long-con-

tinued close interbreeding are not so easily recognised as the good effects from crossing, for the deterioration is gradual. Nevertheless, it is the general opinion of those who have had most experience, especially with animals which propagate quickly, that evil does inevitably follow sooner or later, but at different rates with different animals. No doubt a false belief may unduly prevail, like a superstition; yet it is difficult to suppose that so many acute and original observers have all been deceived at the expense of much cost and trouble. . . . The loss of fertility, when it occurs, seems never to be absolute, but only relative, to animals of the same blood; so that this sterility is, to a certain extent, analogous with that of self-impotent plants which cannot be fertilised by their own pollen, but are perfectly fertile with pollen of any other plant of the same species. The fact of the infertility of this peculiar nature being one of the results of long-continued interbreeding, shows that interbreeding does not act merely by combining and augmenting various morbid tendencies common to both parents; for animals with such tendencies, if not at the time actually ill, can generally propagate their kind. Although offspring descended from the nearest blood relations are not necessarily deteriorated in structure, yet some authors believe that they are eminently liable to malformations; and this is not improbable, as everything which lessens the vital powers acts in this manner. Instances of this kind have been recorded in the case of pigs, bloodhounds, and some other animals." "In the case of man," he elsewhere remarks, "the question whether evil follows from close interbreeding will probably never be answered by direct evidence, as he propagates his kind so slowly, and cannot be subjected to experiment; but the almost universal practice of all races at all times of avoiding closely related marriages is an argument of considerable weight, and whatever conclusion we arrive at in regard to the higher animals may be safely extended to man."

Leaving several minor or little known causes of sterility to be mentioned in the next Lecture, I now turn to other matters in its history which throw light on its theory, and there are two worthy of great consideration. These are the well-known association of dysmenorrhœa with sterility, and the state of sexual appetite and sexual pleasure in sterile women.

Menstruation, when natural or healthy, is attended with no pain, and with little or no disturbance of general health. When there is pain or considerable disturbance of health, the condition is called dysmenorrhœa, and it is plain that the term covers a wide and ill-defined field of disorder and disease. It is with dysmenorrhœa, as thus vaguely defined, that sterility is prevalently believed to be very frequently associated; and there can, in my opinion, be no doubt of the truth of the general belief.

There is a kind of dysmenorrhœa, regarding which I would enter into more details. It is called spasmodic, being regarded as a neurosis characterised by painful uterine spasms, which may be described as having no known object in view. It is often called mechanical or obstructive, terms implying a theory of its cause, and implying also that the spasms are, so to speak, intended for the expulsion of the menstrual fluid accumulating in the uterine cavity and distending it. There is no good evidence of the mechanical obstruction, nor of the accumulation of menstrual fluid, nor of the dilatation of the uterine cavity, nor of the use of the painful uterine contractions; and as all admit the presence of these contractions or painful spasms, I shall call this kind of dysmenorrhœa spasmodic. It is a kind of dysmenorrhœa that is gradually, and I think justly, restricting to itself alone this term—the only real, positive, recognisable uterine dysmenorrhœa, or the dysmenorrhœa proper.

It is of this dysmenorrhœa proper that I am now to speak, and it is known by the following characters. It may occur at any time during the flow of menses, sometimes even before it begins; and, in cases of amenorrhœa, it may occur at the time of the menstrual molimen. In the very great majority of cases it occurs on the first or second day of the flow, and it is generally severer when the flow is scanty than when it is copious. The pain is constant or in pangs; and the pangs may be more or less distinct—in other words, the intermissions of the pain may be more or less complete. The frequency of the pangs varies, five to ten in an hour being common. The pain is rarely accompanied by bearing down, strangury, or tenesmus. It varies in severity, rising occasionally to the intensest agony, with cold sweats, vomiting,

and other symptoms of prostration or collapse. Suffering from it the patient rolls about and groans, and the restlessness is not that of fever, but of gripping pain. It may last only a few minutes, but generally it goes on for hours, the number of hours rarely exceeding four or five. It rarely returns during the current menstrual period. It is generally aggravated by marriage. In women who suffer from this disease there is a super-sensitive condition of the interior of the body of the uterus, and, I think, especially of the internal os uteri, this condition being tested by the contact of a uterine probe or sound.

In making inquiries as to the connection of this dysmenorrhœa proper with sterility, I have frequently, but not always, satisfied myself of the presence of all of these characters. Particularly, I have not classed with this dysmenorrhœa any case in which the severe pain lasted more than a day. In all inquiries as to pain, there is, owing to the indefiniteness of language and the tendency of patients to exaggerate or make light of their troubles, extreme insecurity of statistical statements. I have tried to avoid being misled in 332 cases which I have, during the last five years, taken down in my notes. These 332 cases were all absolutely sterile—that is, all women who had had an abortion or a child are excluded. Of these 332 married women 159 suffered from spasmodic dysmenorrhœa, or nearly half. It is a most grave fault in my argument that I unfortunately cannot give the frequency of dysmenorrhœa among the fertile. But I can meantime only declare the importance of the omission and express my belief, in accord with universal professional opinion, that among the fertile dysmenorrhœa is comparatively uncommon. The connection of a neurosis of this kind with sterility cannot be unimportant, and I cannot leave the subject without expressing my belief of the association of it with abortion and miscarriage also.

Other mutually allied neurotic conditions demand full consideration—namely, sexual appetite or desire and sexual pleasure or satisfaction of the appetite by coitus. In investigating the matter great difficulties are met with from the delicate nature of the inquiry, the difficulty of making sure that the patient understands clearly what is the question to be answered, and the impossibility of finding words of well-defined meaning, or of the same meaning in different mouths. But these difficulties are not insuperable, and error is lessened by relying on a large number of concurring observations.

Sexual desire and pleasure have to be considered separately, because, though they are naturally found combined in the same case, they are far from being invariably so. A woman, with healthy sexual organs, may have sexual desire and no pleasure, or even the reverse, and she may have no desire and yet have pleasure. Although pregnancy and childbearing are natural consequences of sexual desire and pleasure, there is little or no connection between the latter and the wish to bear children. The desire for offspring may be intense, while there is neither desire nor pleasure, and the desire to avoid pregnancy may be intense while there is desire and pleasure. Desire and pleasure may be excessive, furious, overpowering, without bringing the female into the class of maniacs. They may be temporary, healthy, and moderate; they may be absent or null. Instead of sexual desire there may be sexual aversion; and instead of sexual pleasure there may be only feelings of disturbance or pain. Instead of sexual desire there may be intense sexual antipathy, and instead of sexual pleasure there may be severe suffering, even agony in coitus.

The variations of desire are chiefly on the positive side, greater or less. Desire may be absent. From the zero or indifferent condition there is, however, not rarely observed a rise into aversion or antipathy, and this, in married women, without any feeling regarding the husband other than affectionate. It is well known that desire may be fostered at special times by various stimulants of passion; but, apart from such occasions, it may be increased or diminished or annihilated. This is a general belief, and I have frequently had spontaneous testimony of individuals to the same effect. The influence of society and its amusements, of diet, of special kinds of reading, of association with males, is well known and recognised in the increase of sexual desire; and the influence of the opposite conditions, of a truly ascetic life, is equally certain. Desire may, during the childbearing period of life, undergo great changes without any apparent cause; at one time, and it

may be for years, being positive, at another time absent or negative.

Sexual pleasure must not be regarded as in all respects like sexual desire, and requires separate description. Its variations are chiefly on the positive side. It may be absent. Its variations on the negative side are, however, most remarkable. There may be slight or very great suffering, or the intensest agony; and this is often accompanied by more or less active involuntary local sphincteric resistance to penetration, called vaginismus. But the words pain and agony are here used in a quite extraordinary and misleading way. There is no pain, such as that of the infliction of a wound or contusion, or that of toothache or neuralgia. There may, indeed, be in cases of diseased sexual organs, common pain of the kinds mentioned, caused by sexual congress, but of such pain we are not here speaking.

All kinds of pain or discomfort in coitus are often, nowadays, classed as dyspareunia, but I think the word may be well restricted to the condition I am describing: or the condition may be called simple dyspareunia, and there is no common pain in simple dyspareunia. It has an analogue in disgust, but dyspareunia rises to far higher degrees than disgust. As sexual pleasure rises in intensity above all other kinds of pleasure, dyspareunia reaches degrees exceeding those of the intensest disgust. The disgust of a child is often painfully intense, its resistance to tasting and swallowing involuntary and powerful, and often followed by vomiting the matter whether tasted or not; and as all this is not common pain in tasting or swallowing, so dyspareunia is not pain in sexual connection. Sexual pleasure and dyspareunia differ from gustatory pleasure and disgust in this, that while the former are one in kind, and in all degrees excited by the same cause, the latter are various in kind, and elicited by different substances in each case. Pleasure, then, may vary from the intensest to mere indifference; and simple dyspareunia may rise from mere indifference to the highest degree, with sphincteric resistance to penetration, opisthotonos, and a state almost of insensibility.

Pleasure is probably not directly increased by the causes of increase of desire, but the increase of desire is probably a cause of increase of pleasure, as hunger enhances the pleasures of taste. Pleasure is increased by continence and diminished, or annulled or converted into slight dyspareunia by over-indulgence. Sexual pleasure may vary without apparent cause, disappearing for short periods or for years, and reappearing with the same appearance of caprice. Pleasure is frequently absent at marriage and gradually developed during the continuance of that state. If it is slight at marriage, then coitus will be painful, the common and not simple dyspareunic pain overpowering the pleasure and preventing it.

Describing the lower animals in this respect, we guess by aid of analogy, but the analogy is so strong as to endow the guess with a high degree of assurance, reaching nearly to certainty. We may be sure that animals, generally, feel sexual desire, and that this sexual desire occurs normally or naturally only in connection with fecundity. In many domestic, or otherwise well-known animals, there is sexual desire only in the rutting season, and at other times not only an absence of sexual desire, but a positive sexual antipathy. A bitch not in heat will angrily resist any attempt at sexual approach by the male, while quite ready for any other kind of play. Of sexual pleasure in female lower animals we know very little, but we may be sure it exists. Of its existence in males we have abundant evidence, and we may thence argue that it exists in females. Nothing is commoner in dogs than what may be called masturbation. This kind of sexual pleasure is generally believed to be increased by confinement, and the evidence afforded by zoological collections is held to be good.

I know nothing regarding the connection of sexual pleasure in animals with fertility or sterility, but we have the testimony of Darwin of the presence, in animals that are confined, of sexual desire, sometimes in excessive degree; sexual indulgence being held as evidence of sexual desire; and the sexual excess is often connected with sterility.

" says he, in the Nine-Year Report from the Zoological Gardens, are stated to unite most freely, but through many individuals were kept, 'although many of the felines breed readily in the Zoological Gardens, yet copulation by no means always follows union. In the Nine-Year Report various species are specified which

were observed to couple seventy-three times, and no doubt this must have passed many times unnoticed; yet from the seventy-three unions only fifteen births ensued." In many animals under confinement there is no coupling, and this may be assumed to indicate absence of desire in female as well as male.

It is an almost universal opinion that in woman desire and pleasure are in every case present, or are in every case called forth by the proper stimulants. The opinion is founded on experience, and it is, no doubt, nearly true; but the exceptions to the rule are numerous and important. It is also a popular opinion that desire and pleasure are essential elements in fecundity, and in cases of rape followed by pregnancy, that consequence has been made ground of defence against the charge. Great authors, among whom is Ambrose Paré, recommend the excitement by dalliance of great desire, as a remedy of sterility.

I think it is very nearly certain that desire and pleasure in due or moderate degree are very important aids to, or predisposing causes of, fecundity, not on account of their own proper attractiveness, but on account of some connection between them and the perfection of other parts of the complicated proceedings which result in fecundation. But this is only a firmly held opinion, for I can give no conclusive evidence or proof of it; and this absence of proof diminishes greatly the value of my observations on the absence of desire and pleasure in the sterile. The want most acutely felt here is a knowledge of the state, in this respect, of the fertile. In producing evidence as to the sterile, I shall assume that sexual desire and pleasure are very rarely absent in the fertile. Excess of sexual desire is probably unfavourable to fertility. It is recognised chiefly by excessive indulgence in sexual pleasure, and is observed in the weak and ill-conditioned, in imbeciles and idiots, as it is also in animals under confinement. Excessive indulgence in sexual pleasure is also probably unfavourable to fertility, or a cause of sterility; and it probably is specially influential in the young, as it may also be in prostitutes. In these circumstances the births of females are, on good grounds, believed to be far above the ordinary average, in proportion to males.

Masturbation in females is an unnatural and generally excessive indulgence in artificial sexual pleasure. It has always appeared to me to affect especially children and young women of weak mind. I have often been struck by the smallness or imperfect development of the external parts in young women who masturbate, and I have not rarely observed what appeared excessively high development of sexual desire in women who had imperfection or absence of internal genital organs. In one, dissection revealed the presence of ovaries and Fallopian tubes only. Some confirmation of these views may be found in cases such as that of Campbell, (a) in which a woman addicted to masturbation had never menstruated, and had imperfectly developed genital organs; she had, however, also a dermoid cyst of the ovary. Aran (b) has a case, of what he describes as frightful excess of masturbation, in a young woman dying of phthisis, whose uterus and appendages were found to be very imperfectly developed. Kussmaul (c) mentions the concurrence of masturbation and nymphomania with imperfect development of the uterus and the genital organs; and Joulin (d) refers to a case of Vaddington's where absence of naerus and exaggerated sexual appetite were combined.

Entire absence of desire and pleasure, or of one of them, or the presence of intense sexual antipathy and dyspareunia are not necessarily causes of sterility. It is not at all rare for women to be pregnant and bear healthy children who aver in the distinctest manner not only absence of desire and pleasure, but presence of the opposite conditions. But the following statistics make it highly probable that absence of desire and pleasure and the presence of their opposites are powerful influences favourable to sterility. The statistics do not indicate what was occasionally found—namely, that desire was present while pleasure was absent; or, in other cases, that desire was absent while pleasure was present. The cases observed were all in women absolutely sterile, of whom the great majority consulted me regarding the sterility. Among 191 sterile wives desire was absent in 89, or in about 1 in 4. Among 196 of the same sterile wives pleasure was absent in 62, or about 1 in 3. The figures

show that many sterile wives had desire but no pleasure. They do not show, what nevertheless is true, that some had pleasure who had no desire.

TABLE XXIII.

Class-book Table of Desire and Pleasure in Sterile Women.

Age at marriage.	No.	Desire.			Pleasure.		
		Pre-sent.	Ab-sent.	No note.	Pre-sent.	Ab-sent.	No note.
15 to 19	59	18	4	37	15	8	36
20 to 24	220	78	18	124	69	27	124
25 to 29	134	85	12	87	31	18	85
30 to 34	69	16	3	40	14	5	40
35 to 39	23	3	1	19	3	3	17
40 to 45	9	2	1	6	2	1	6

I have a strong impression, derived from all I know and have observed, which I may express theoretically, that while in healthy normal women there is abundance of sexual or reproductive energy for fertility and all its accompaniments, in many sterile, or relatively sterile, women, there is deficiency which may be exhibited in one or another, or in all the ordinary evidences of reproductive energy, and that excess or deficiency in one department may be associated with deficiency or excess in another. It would seem that in women of deficient reproductive energy, excess in one department might be compensated by deficiency in another, and *vice versa*, there being only a limited store of the original energy. In illustration, a remarkable class of cases may be cited, which I shall sufficiently describe by stating generally the chief points in one:—A robust healthy woman is married at eighteen; she bears three children and has four miscarriages before she has passed twenty-three years of age. Up to the birth of her last child, and for five years subsequently, she experiences no sexual desire, and has no pleasure. Five years after her last pregnancy she almost suddenly comes to have intense desire and pleasure, but remains sterile for four additional years before she seeks a cure of her sterility. Fertility present, while desire and pleasure are absent; sterility present, while desire and pleasure are present.

THE CAUSES, SYMPTOMS, AND TREATMENT OF PHIMOSIS AND PARAPHIMOSIS. (a)

By LAMBERT H. ORMSBY, F.R.C.S.,
Lecturer on Clinical and Operative Surgery.

THE term phimosiis signifies an elongated condition of the prepuce or foreskin, whereby it is so tightly contracted in front that it cannot be drawn backwards so as to uncover the glans penis. It is of two kinds. 1. Congenital; 2. Acquired. The first variety is very frequently met with in young male infants, and in some it assumes a very aggravated form; so much so, that the prepuce is found so much contracted as to prevent the water being passed without great difficulty, and in certain instances, when the water is being passed, owing to the very contracted condition of the orifice of the prepuce, the urine escapes between the glans penis and contracted skin, and very soon the whole cavity of the prepuce becomes filled with urine or as it is termed "ballooning." This, in due course, gives rise to great pain and other complications.

Phimosiis is attended with many inconveniences, among which may be mentioned the retention of the secretion poured out naturally about the glans, and which, not finding a ready and easy exit, produces in a short time, irritation, pain, to be followed by excoriation, ulceration and its consequences. Also when this condition is present, ablutions, and careful washing of the part cannot be attended to, and from this cause a most unpleasant odour from the organ is very frequently observed.

A person suffering from phimosiis, when indulging in sexual intercourse, is far more liable to contract gonorrhoea or chancre (provided the sexual intercourse be impure) than those who do not suffer from this contracted condition of foreskin, or those who have their glans perfectly denuded and bare naturally.

In impure connection the subsidence of the penis after erection favours the easy transit of the contagious vaginal discharge to a resting place either in the orifice of the male urethra, or between the skin and glans penis, where it remains in contact with the mucous membrane pent up, producing, in due course, from its acid character, excoriation, ulceration, or chancre.

In my recollection I have seen far more cases of gonorrhoea and chancre in those with elongated prepuces than those who have naturally the glans penis denuded of foreskin. Nor is the cause difficult to understand for the reasons above mentioned.

The consequences of congenital phimosiis, whether local or remote are sometimes very serious, among which may be mentioned—1. Local irritation; 2. Balanitis; 3. Calculous concretions. 4. Dried indurated pent up secretion between glans and prepuce. 5. Ulceration followed by adherence of the prepuce to the glans. 6. Urinary obstruction and bladder irritation. 7. Masturbation. 8. Reflex convulsions, and infantile paralysis of the lower limbs (Sayre). 9. Incipient hip disease (Barwell), and finally, I have met with epithelioma of the prepuce in middle aged men, due to this contracted condition of parts, and the consequences thereon.

Phimosiis exists in a great many cases that never apply to a surgeon; and the few who do are compelled to do so from pain, swelling, and owing to the great delay and difficulty in passing water.

Causes.—In examining carefully a well-marked case of phimosiis it is found that the external skin is quite lax, and very dilatable; while the internal mucous membrane is the part that is so tight and contracted; and, after a time, the mucous membrane of the inner surface of the prepuce becomes permanently adherent to the glans, rendering the operation for its relief, when present, most difficult. It is also found in young male children that the aperture of the prepuce, although very small, gradually enlarges as the child grows older, and all the bad consequences which the phimosiis might have otherwise occasioned in disease are thus avoided. Young mothers are sometimes very anxious about this condition, being told by some old and trusty nurse "that she thinks the child is not right, and she ought to speak to the doctor about it." The anxiety in such parents may, however, be allayed by telling them if the prepuce can with ease be drawn so far back as to display the top of the glans penis they need then have no fear about the matter, and in due course the prepuce may, and will be drawn backwards to the fullest extent.

On two occasions I have been consulted by newly married men to relieve them of paraphimosiis, the result of having frequent connections when they were naturally affected with phimosiis. I also saw a gentleman not long ago, for paraphimosiis, which was produced from the same condition of parts, which was the result of an attempt at the first sexual connection he ever had in his life.

It is worthy of mention when considering the after consequences of phimosiis, that out of twelve cases of amputation of the penis for cancerous disease performed by the late Mr. Hey, nine of these cases were affected with natural phimosiis. Mr. Roux noticed the same thing in similar examples, and as this distinguished surgeon considered, it may conduce to carcinoma of the penis. This condition of contracted prepuce, when present, ought to be always remedied in time.

Treatment of Congenital or Natural Phimosiis.—Before having recourse to operative measures for this condition the surgeon will be anxious to know what are the positive indications for such treatment, for in some mild cases the patient, or his friends, are quite satisfied to

(a) Being a clinical lecture delivered in the Meath Hospital and Co. Dublin Infirmary.

allow him to remain as he is without having anything done. However, I would recommend steps to be taken if the orifice in the prepuce was smaller than the orifice of the urethra, for if this condition is present, the prepuce "balloons" during micturition, viz., the urine flows more rapidly into the preputial cavity than it can escape from its orifice. Such a condition, sooner or later, is followed by preputial inflammation, ulceration or adhesion, and retention of secretion.

Van Buren says: "When, therefore, the prepuce of an infant balloons during micturition, phimosis exists, and circumcision should be performed."

The various plans recommended from time to time for the permanent relief of congenital phimosis may be enumerated as follows:—1. Manipulation or gradual dilatation, and retraction; 2. Mechanical dilatation by means of forceps, glove-stretcher, and sponge tents; 3. Longitudinal incisions made in the mucous membrane; 4. Single incision of the prepuce on director; 5. Complete circumcision.

1. *Gradual Retraction by Manipulation.*—In some mild cases this plan succeeds very well. The patient should endeavour, frequently in the week (say night and morning) to make an attempt to draw back the skin over the glans. He may be facilitated by distending the prepuce with warm water or glycerine water, or warm oil introduced with some force by means of a medium-sized syringe, anointing the part with vaseline. In carrying out this treatment the patient ought to be warned that he may produce paraphimosis by too violent an attempt at retraction. When the prepuce can be drawn back so as to uncover the glans halfway, the treatment may be discontinued. If the contraction has been acquired by cicatrices at the orifice, this treatment, as a rule, is not very successful.

2. *Mechanical Dilatation by Forceps and other means.*—Dr. Cruise, of Dublin, recommended that the preputial orifice be stretched and distended by means of the forcible and gradual divarication of the blades of a forceps made for the purpose. In some cases the use of such a forceps has proved useful. Compressed sponge and sea-tangle bougies have also been used to distend a tight preputial orifice. A small, nicely-rounded glove-stretcher has also been pressed into service to carry out the same object. I cannot say much for this line of treatment. I have tried it in a few cases and have not, up to the present, been pleased with the results.

3. *Longitudinal Incisions made into the Mucous Membrane from the Inside.*—Parallel incisions made into the mucous membrane of the prepuce have been recommended and practised for the purpose of relieving the contraction of the structure. A very long, narrow-bladed knife must be used, and care must be taken so as to be sure that the mucous membrane is the only part that is scarified when the tightness has been thus relieved. The external skin becomes as lax as possible, and can with ease be drawn backwards over the glans. After the inside of the prepuce is well scored it bleeds at times freely, but is soon controlled by the application round the top of the penis of strips of lint steeped in some cold evaporating astringent lotion. When these parallel incisions are made the prepuce must be drawn forward and put on the stretch, a director must then be passed in through the preputial orifice until it is stopped by the reflected mucous membrane from the glans to the prepuce. The longitudinal incisions are then made into the prepuce. The use of the director is important, as it prevents the chance of the operator scoring the glans or entering the orifice of the urethra with the point of the knife.

(To be continued.)

DR. COLEMAN, of Woolwich, has been presented with a handsome carriage clock in recognition of his gratuitous instruction in the St. John's Association at Charlton.

AN ESSAY UPON HIP-JOINT DISEASE.

By S. D. CLIPPINGDALE, M.D., F.R.C.S.

(Concluded from page 201.)

VI.—THE TREATMENT—(Continued).

Summary of Treatment by Rest and Extension.—In the first stage or early part of the second, when the joint is either in a state of simple inflammation or contains fluid of a simple character, synovial or serous, the joint should be placed in a state of absolute rest. At this time extension will do no good, and may do harm, for when a joint contains fluid, extension increases the pressure and produces pain; and no moderate extension at this early stage is capable of drawing apart the inflamed surfaces. Nor is extension necessary to reduce a limb from a flexed to a straight position. This can easily be effected by the weight of the limb itself, provided that muscular opposition be overcome. The muscles contract in order to keep the joint at rest. When, therefore, rest is secured by artificial means, the muscles perceiving their occupation to have departed will allow the limb to be brought into proper position. It is in the third stage that extension is necessary, and the indications for its use are—1. A tendency to dislocation; and, 2. The occurrence of "grating," indicating opposition of carious surfaces. If, however, ankylosis of the carious surfaces be desired, then, of course, extension is inadmissible.

The plan of treatment by rest and extension is successful in nearly every case in which suppuration does not occur; and when suppuration does occur, this plan may vie with operative treatment in its results. For, if pus form and be evacuated, and, by means of rest, ankylosis be produced with the limb in a useful position, then it is doubtful whether this result is not as good as any that might follow the operation of excision.

The period required for treatment by rest and extension is an obstacle to its use among the poor unless the patient be in a hospital. The duration of the treatment varies. The maximum time in most cases is about three years, but every practical surgeon is aware that, unfortunately, a case may last nearly a lifetime, cut short perhaps by some secondary and consequent disease of a vital organ.

Operative Treatment.—In those cases, however, in which the treatment by rest and extension is inapplicable, or, having been applied, has failed, it becomes necessary to resort to operation, and two procedures are practicable—excision and amputation. It is proposed to discuss briefly each of these.

The Operation of Excision, as the reader will remember, was first suggested by Mr. Charles White, of Manchester, in the year 1769, and first performed by Mr. Anthony White in the Westminster Hospital in the year 1821.

As to the Indications for Excision.—It is scarcely necessary to reproduce here all the views held upon this subject. Mr. Anthony White performed his operation in order to remove the dislocated head of the femur from the dorsum of the ilium. Many eminent surgeons—notably, Mr. Croft, of London, and Mr. Barton, of Dublin—consider that the operation is called for; and if performed, is more generally successful when done earlier than is the custom with many surgeons. Mr. Croft's cases were investigated by a committee of the Clinical Society, and the report of this committee is as follows: that "in a total of 32 cases, 10 were operated on before the disease had lasted six months. Of these, 6 died and 4 recovered—that is, 60 and 40 per cent. respectively. Twenty-two were operated on after the disease had lasted more than six months, and of these 9 died and 13 recovered—that is, 41 and 59 per cent. respectively." Mr. Croft's statistics, therefore, do not seem to support his doctrines. But although this is the case with Mr. Croft's cases, it is different with those reported by others. Thus, in 90 cases of

excision performed by four surgeons—viz., R. W. Parker, of London, Alexander, of Liverpool, Annandale, of Edinburgh, and Sayre, of New York—it is found that at the time of operation the disease had lasted less than six months in 20 and more than six months in 70. Of the 20 patients, the subjects of early operation, 4, or 20 per cent., died; while of the 70 operated upon in a later stage 22, or about 31 per cent., died. The result in these cases, therefore, as far as mortality is concerned, is evidence in favour of early operation.

The committee appointed by the Clinical Society to investigate this subject of excision report that they consider the operation should be performed:—

"1. When suppuration occurs early—that is, in the course of a few weeks after the onset of the disease—and is accompanied by severe local and constitutional symptoms—pain, night screaming, wasting, and high temperature. These symptoms, though they are sometimes due to acute synovitis followed by ulceration of the articular surfaces, may yet generally be taken to indicate that acute inflammation has resulted in necrosis, either of the entire head or neck of the femur, or of the acetabulum. In these cases, however, it may not always be necessary to perform a systematic excision, for sequestra can sometimes be found and removed without sacrificing the articulation.

"2. When, in a case of suppuration, enlargement of the liver, or albuminuria, indicating the presence of degeneration of the viscera is detected.

"3. When suppuration continues to be free, and when fresh sinuses are formed; or when extensive burrowing is still in progress, and the patient is materially losing ground, in spite of careful treatment by rest and free drainage.

"4. Disease of the pelvis does not, in the opinion of the committee, preclude excision. On the contrary, the operation seems rather to be called for, since, in many cases, it is the only means by which, when suppuration occurs, efficient drainage can be provided. If swelling can be felt in the pelvis near the floor of the acetabulum by the finger passed into the bowel, in a case in which there is a sinus freely discharging, and in which the general health is declining, it is probably best to resort to excision. It must, however, be borne in mind that pelvic disease is always formidable, and that it renders the prospect of recovery, under whatever treatment is adopted, more than usually doubtful."

The evidence as to the results of operative and non-operative treatment obtained by the committee was as follows:—"The results obtained on the one hand by excision, and on the other by rest and extension, in the cases tabulated above, show a total mortality in cases treated by excision 40 per cent., as compared with 33·5 in cases of suppuration treated by rest and extension; or if deaths by causes unconnected with the disease be excluded, the mortality is 37·7 as against 31·6; or excluding cases of death in which the joint affection was cured, the mortality is 35·5 as against 30·4."

The report of the committee expresses so well the views held by surgeons of the present day that I would be unwilling, even if I were able, to add to or criticise it; yet, I would venture to refer to two points of some importance in the performance of the operation. Firstly, as to the use of antiseptic (Listerian) precautions; experience has convinced me that even although air may have entered the joint cavity through the sinuses long before the operation, nothing is lost and much may be gained, especially as far as the personal comfort of the patient is concerned, by the use of this method. Secondly, I think it is open to discussion whether the use of the gouge should not be abandoned. This instrument is used to remove necrosed bone from the floor of the acetabulum, with the result, I believe, of producing, not unfrequently, a perforation, with subsequent intra-pelvic mischief. The caries of the acetabulum being caused by the friction of the head of the femur will, in most cases, cease as soon as the head is

resected, rendering unnecessary the doubtful expedient of gouging the thinned and unseen floor of the acetabulum.

Amputation, the second of the operative procedures, sometimes required in hip disease, may be necessary either as a *primary* or *secondary* operation. *Primary*, if in a case of the disease, the shaft of the femur may be so diseased that removal of the joint alone would not ensure a useful limb. *Secondary*, when, after excision, the limb is useless from defective ankylosis or the patient's life endangered by prolonged suppuration at the seat of excision.

VII.—THE CAUSE OF DEATH.

Death may be produced in three ways. 1. By protracted suppuration; 2. By secondary complication of internal organs; or 3. By the operation.

The average total mortality from all causes varies between 30 and 40 per cent.

Much valuable information as to the cause of death is to be found in the report of the Clinical Society, and I will not draw further upon the wide store of statistics contained in that report than to borrow from it the following tables of 109 cases of death:—(a)

Analysis of 96 Deaths after Suppuration.

Meningitis	16·7
Albuminuria with dropsy	20·8
Phthisis	5·2

Analysis of 13 Deaths in cases of Non-Suppuration.

Meningitis	7
Phthisis	1
Tubercular pneumonia	1
Croup	1
Intercurrent disease (nature unknown)	1
Cause unknown	2

If, from the above tables, we exclude the cases in which the cause of death was unknown, we find that tubercular disease, in some form, caused death in 65 per cent. of the cases, other diseases in about 25 per cent., and the effects of operation in about 10 per cent.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Reported by JOHN W. MARTIN, M.D., Sheffield;

Formerly Assistant Surgeon, Mayfield Factory Dispensary, Portlaving.

Arrested Menstruation—Pain and Tenderness in the Uterine and Right Ovarian Regions—Pains down the Right Thigh, and in the Right Knee joint—Sensation of Chills up the Spine—Headache—Insomnia—Nervous Excitement and Restlessness—Pyrexia—Treatment—Recovery.

On the 14th of February, 1883, I was asked to see Mrs. B., æt. 31, the mother of four children, her last child having been born about a year ago—an only son, of whom she was very fond and proud, and whom she had the misfortune to lose in November last. The nursing, anxiety, and grief connected with his illness, and death, seriously affected her general health. She has never been quite regular as regards her monthly health, the catamenia being at times profuse, at others scanty, and at all times accompanied by more or less excess of pain. In temperament she is nervous and excitable. Suffered lately a good deal from loss of sleep, and for a long time after her loss she felt languid, and unequal to exertion, and had no desire or relish for food.

On Saturday, Feb. 10th, the menstrual flow appeared slightly. On Tuesday, the 13th, she did a great deal of walking, and was a good deal fatigued. She felt, however, very

(a) Clinical Society's Transactions, vol. xiv.

well, ate a good dinner, and went to bed apparently in good health. About 1 a.m. she woke up with violent pain in the region of the uterus and right ovary. The pain was very violent whilst it lasted, and was paroxysmal in character. This continued for the rest of the night. In the morning her husband called, asking me to see her. He is accustomed to the use of the clinical thermometer, and reported the temperature as slightly below normal. This was at 8.30 a.m. I saw her at 9 a.m., and then found her in a nervous, excited condition, very restless, with the pain recurring at frequent intervals, the pain, as already described, being referred to the region of the uterus or right ovary. There was decided tenderness over the seat of pain. The menses had been checked. She complained of frequent chilly sensations running up the spine, and of headache, always increased after one of these attacks of chill. She is in no sense a hysterical woman, or inclined to make the most of symptoms. On the contrary, she was most anxious to be well, and to do anything and everything to get so. I found the temperature 101°, her pulse 100, and her tongue lightly furred. The bowels were quite regular. She passed a sufficiency of water, normal in colour, and free from deposit. She was most anxious to get some sleep and rest. There had been no nausea or vomiting, nor was she troubled with flatulence. I ordered a turpentine stupe to be applied to the seat of pain, to be followed up by frequent relays of hot poultices, the poultices to be covered with lanthanum poured over their surface, and prescribed the following mixture:—

R Potass. bromidi, ℥ij.;
Potass. bicarb., ℥j.;
Tr. aconiti, ℞ss.;
Vini ipecac, ℥j.;
Syrupi zingib., ℥i.;
Aque chloriformi; ad ℥viiij. M.

℥j. to be taken with one of the powders every third hour, effervescing.

R Pulv. acid. citric., gr. xij.
℞ pulv. Mitte viij.

Sig. "Powders."

At 2.30 p.m. her husband called again to see me, as he found the temperature steadily mounting, it being, at 2 o'clock, 103°. The chills up the spine were more frequent in their recurrence. She had got no rest, and seemed very restless and feverish. The pain was easier, but the headache was worse. The medicine had not been obtained until 11 a.m., and she had had but one dose. I ordered him to give another dose of the mixture at once, and told him I would call at 4 p.m. On getting there, I found her still very restless and excited, and longing for sleep. The pain was much easier, recurring at rarer intervals, and much diminished in intensity. The pulse was 104, and the temperature 103° 6, still rising. She felt pains down her right thigh and in the right knee-joint, and a dull, aching pain in the small of the back. The case now looked serious, more especially as they were about leaving Sheffield the following week, and a long illness would be the source of the greatest inconvenience. I was shut out from the use of opium or chloral, having learned that, on a former occasion, when tried, they failed entirely in obtaining the desired effect, and gave rise to a most distressing train of symptoms. I ordered a dose of the mixture to be given every hour and a-half, and the temperature to be taken every hour. The following is a table of the temperatures and pulse rate as taken:—

	Temp.	Pulse.
Feb. 14th.— 8 a.m. ...	98°	
9 " ...	101	100 Full and
2 p.m. ...	103	resting.
4 " ...	103·6	104 Full and
5.10 " ...	102·8	resting.
6.15 " ...	102·7	
7.30 " ...	102·5	
8.30 " ...	103	92 Softer.
9.10 " ...	102·8	
10.30 " ...	102·5	92 Softer.
Feb. 15th.—12.15 a.m. ...	102·7	
2.30 " ...	100·9	
7.30 " ...	98·9	
8.45 " ...	97·8	84 Compressible,
12.30 p.m. ...	98·6	but quite re-
2.30 " ...	98·2	gular.
5.20 " ...	98·8	after taking some hot
7.15 " ...	98·0	68 [tea.
9.30 " ...	97·8	

I directed that the mixture should be withheld, or given at longer intervals should a rapid fall in the temperature take place. By 9.10 p.m. the pains recurred at very long intervals, and were very slight. There had been a slight return of the menstrual discharge. The chills were no longer felt, and the headache was better. The pains down the thigh and in the knee-joint were much better. I ordered a warm bath to be taken, and she felt, after taking it, much refreshed and composed, being inclined to sleep. When I left the house at 12 midnight, there was every promise of a quiet night and steady improvement.

Next morning, at 8.45, I found my hopes realised. She was in every way better. She had rested fairly during the night. The temperature and pulse were down—the one to 97·8°, the other to 84, soft, compressible, and quite regular. The tongue was clean, the bowels had acted pretty freely, and she was passing a sufficiency of normal urine. She had lost all traces of nervous excitement, and was free from headache. There were still slight returns of the uterine and ovarian pains, but these were very slight indeed. I now ordered the mixture to be given only every fourth hour; the poultices to be replaced by cotton wool; the diet to be as before—milk, light pudding, and soups. In the evening I stopped the mixture, ordering for next day—

R Potass. bicarb., ℥j.;
Tr. nucis vom., ℥j.;
Sp. am. aromat., ℞ss.;
Infusi gent. co., ℥iv.;
Aque ad ℥viiij. M.

℥j. to be taken an hour and a-half after meals. The subsequent course of the case was one of steady convalescence.

I regard the case as interesting from a therapeutical point of view. I certainly feel convinced that there was cause and effect in the results of treatment in steadily pushing the bromide and aconite in such large and frequent doses. The counter-irritation and poulticing alone had failed to give relief to the general *malaise* and constitutional disturbance, nor was there very decided improvement until the medicine had time to take hold on the system. The physiological effect of the aconite was felt slightly at the tips of the fingers, but at no time was there any great nervous depression. The case is also, I think, of interest as a faithful record of symptoms observed, and of the manner in which they were dealt with.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 30TH.

The President, ANDREW CLARK, M.D., LL.D., in the Chair.

THE sub-committee appointed to inquire into Mr. Shuter's case of Sub-Periosteal Amputation presented their report, in which the following conclusions were expressed:—(1) That the firm resisting core existing in the stump and to which the muscles were clearly attached did not present indications to warrant the opinion that it was really osseous in structure; (2) That the muscles of the stump, notwithstanding, acted efficiently from their attachment to this core; (3) That the method of amputation followed by Mr. Shuter offered obvious advantages in that it diminished risk from hæmorrhage, and tended to preserve the attachment to the muscles as successfully as though the operation had been performed on the middle of the thigh by ordinary amputation. From examination of other cases also, the committee found nothing to justify the statement that reproduction of complete bony structures had taken place.

MR. ROBERT WILLIAM PARKER ON

A CASE OF CONTUSED WOUND OF THE THIGH AND LEG IN A CHILD—GANGRENE OF LIMB—DEATH.

A female child, aged 14 months, was admitted into the East London Hospital for Children, having sustained an extensive wound of the left leg 24 hours previously. The wheel of a heavy dray had caught the outer border of the limb and torn off a large *crescentic* flap of integument; the front of the knee-joint was exposed but not opened. An attempt was made to clear off the mud, with which it was plentifully covered, and so establish an *aseptic* condition,

after which antiseptic dressings were applied. The child appeared to be doing well for about 36 hours, after which she became drowsy and restless, and some livid patches and oedema appeared on the foot. Twenty-four hours later, these symptoms had become more pronounced, and on the following morning extreme gangrene of the limb had supervened. She died. The author sought the opinion of the members of the Society (1st) on the treatment he had adopted, and (2nd) as to the cause of the gangrene. He felt that amputation in the upper third of the thigh, the only alternative, was a severe operation for such an infant; while the suppuration and granulation of such a wound, unless they ran an aseptic course, would almost certainly have proved fatal. As regards the gangrene, no injury to the vessels could be discovered as a cause. Could the action of the carbolic acid have produced such a result?

Mr. PAGE observed that many important questions had been raised in Mr. Parker's paper. He himself had under his treatment a similar case five years ago. A child, eighteen months old, was injured on the arm by a swing gate. She was admitted by the house-surgeon and seen twenty-four hours after by Mr. Page, the arm being then dead and inflammation spreading up from it. Against the advice of his senior colleagues Mr. Page at once amputated at the shoulder, and the child made an excellent and rapid recovery. A fracture existed in the limb removed at the lower end of the humerus and involving the olecranon; the brachial artery was plugged by thrombi, but the outer coat of the vessel showed no signs of injury. He regarded it as of importance that a definite rule for guidance in such cases should be laid down, and that speedy amputation should be resorted to for removal of dead from living structures, and consequent avoidance of danger from sepsis. The measure of interference should be indicated by the constitutional disturbance set up, and there should be no waiting for the appearance of a line of demarcation between the dead and living tissues. There had been no injury to the nerves in the case mentioned by him.

Mr. CRIPPS, while admitting that there were numerous varieties of "traumatic gangrene," urged the importance of an accurate definition of the term. In illustration of the distinctions he wished to enforce, he quoted several cases. The first was that of a man, who, falling down a lift, sustained a severe shock and laceration of the thigh and wrist. There was dyspnoea. The arm was carefully placed in splints, but next day, the fingers being discoloured, the splints were removed; the darkness, however, spread upward, the pulse became small and rapid; temperature remaining about 99°; the arm was removed at the shoulder. No relief followed the operation, and next day gangrene supervened in the foot, spreading up to the thigh. Death. The post-mortem showed that the arteries were pervious, but that venous occlusion existed. There was fatty heart, and old adhesions of pleurae and pericardium, and several fractured ribs. Mr. Cripps argued that in this case gangrene had been accelerated by the lowered circulation of the patient, the blood, in consequence of it, clotting in the main vein of the affected limb and that in such a case amputation could avail nothing, inasmuch as the gangrene was nothing more than a local sign of commencing somatic death. In another case a man was injured by a piece of gauze near the thumb. Three or four days afterwards pain compelled him to seek hospital relief, at which time there existed swelling of the hand and forearm, and blackening of the fingers, but the back of the hand was very red. Pulse, over 100, temp. 104°. Twenty-four hours later amputation at the shoulder was performed, followed by marked relief of pain, reduction of temperature, and general improvement lasting two or three days. At the end of the fourth day, however, rigor came on, the stump swelled, gangrene spread from it to the face, and death occurred after fourteen hours of agony. Amputation at an early period might have saved this case, which was instanced as an example of acute spreading gangrene, a form of the disease to be met by resort to amputation high up at an early period. In the first case the man had not been actually ill previous to the accident; the second patient was a steady, sober workman.

Mr. HEATH was of opinion that, considering the age of his patient, Mr. Parker had acted rightly in pursuing the course he adopted. The gangrene was undoubtedly due in this case to the original injury, and was of a kind in which the appearance of a line of demarcation was to be expected. He was convinced that harm was done by lowering the temperature of

the patients by means of the carbolic spray. A month ago he amputated at the thigh in a case of a woman, who died twenty-four hours later, and whose death he attributed to the combined influence of the spray and the carbolic acid absorbed during the time the operation took to be performed. There was no carboluria, and probably death was due to the fact that the kidneys failed to throw off the acid taken into the system. He imagined Mr. Parker's patient had suffered in a similar way, from absorption of carbolic acid, and reduction of temperature due to the cooling influence of the spray. The suggestion made to maintain warmth in such cases by means of a hot poultice or equivalent dressing was a very valuable hint. The child, however, would probably have died in any case. The mud mentioned by Mr. Parker might not of itself have done much harm, but it should be remembered that were such things as mortal injuries; from the way in which surgeons were accustomed to talk it would almost seem as though every injury could be cured by operative means, and that no accident ought to prove fatal in the hands of modern operators.

Mr. PARKER said he had been surprised at the onset of gangrene, because the wound was comparatively so slight, affecting only the integument. He did not think the case quite similar to that related by Mr. Page. He had dreaded septic inflammation in the limb, and on that account had applied the dressings mentioned. He believed the use of the spray contributed to the fatality.

Mr. W. SPENCER WATSON on a case of

TETANUS.

A well-nourished boy, *æt.* 8, came under treatment eleven days after receiving a small lacerated wound on the dorsum of the foot. Four days before admission, symptoms of tetanus commenced, and on admission the convulsions occurred about once every half hour. At first the temperature was 101°0', but afterwards was very little above the normal standard, being 99°4', but the pulse and respiration were much accelerated. The temperature on the second day was 100°2', and continued at that height till the fourth day, when it went up to 103°2'. He died the same evening. He was treated by the administration of chloral, with occasional morphia injections and rather free purgation. A mustard plaster was applied to the spine. During the third day a severe spasm terminated by sudden cessation of breathing, but artificial respiration succeeded in restoring him. He died in a similar spasm ten hours afterwards. The post-mortem examination showed that the membranes of the brain and cord were intensely congested, but the substance of both appeared healthy. Microscopic sections of the cord gave chiefly negative results. The only appearances that seemed abnormal were the presence of slight vacuities in the grey matter surrounding the vessels and the multipolar cells. It was thought, however, that these spaces were due to the method of preparation of the sections. There was no exudation, either in the spaces or in any part of the cord examined, except in some sections of the dorsal region, which presented colloid bodies here and there, such as those described by Dr. Ross. Sections of the peroneal nerve exhibited changes, probably due to inflammation, chiefly affecting the sheath and neuroglia. The questions raised by the case were—1. Would the performance of neurotomy or amputation at an early stage of the case have given the patient a better chance of recovery? 2. Was the treatment by chloral and morphia the best adapted to the circumstances of the case? 3. Is the case an argument of any value as showing that the microscopic appearances of the cord are sufficient to demonstrate the essential tetanic condition? or are we justified in assuming that at present the microscope fails to give any reliable information, and that the essential changes in tetanus are too subtle to be discoverable by any of the means of post-mortem inspection that we at present possess?

Mr. HOWARD MARSH on

TETANUS FOLLOWING LACERATION OF THE TOES, AND LASTING FORTY-TWO DAYS—SYME'S AMPUTATION—RECOVERY.

Alfred M., *æt.* 8, was knocked down on September 9th by a tramcar, which passed over his left foot, severely crushing the three inner toes. On September 12th he came into St. Bartholomew's Hospital with the toes gangrenous. On September 23rd tetanus set in, and in the next twenty-four hours rapidly increased in severity, and was attended with frequent and urgent spasms. Syme's amputation was performed in

the afternoon of the 24th with the effect that the spasms were both less frequent and less violent. Tetanus, however, continued severe for the next thirty-five days, and then gradually subsided, to cease entirely on the forty-second day. The wound healed slowly, but without complication. It was all but closed at the end of a month after the amputation. Treatment consisted in the administration of an abundant fluid diet, the frequent use of nutritive enemata, and the employment of enemata of chloral and bromide of potassium, and of the hypodermic injection of morphia. The chloral and bromide injections did very little, if any, good. But morphia always relieved the spasms and procured rest, though only for short periods. On many days, upwards of two grains were injected, as much as five-twelfths being injected at a time. The author remarked that the case was rare not only as an instance of recovery from severe traumatic tetanus, but also on account of the prolonged period (forty-two days) over which the disease extended. Though many authorities were opposed to amputation, he resorted to it in this instance because the operation was not a large one, because the foot was already in part gangrenous, and because amputation afforded the surest means of removing peripheral irritation—a principal indication in the treatment of tetanus. He did not resort to nerve division, as this might fail to check irritation, and he did not know which of the several nerves ought to be divided. In the present instance morphia was the only drug that seemed useful, and, though employed in such large doses, it produced no unfavourable result.

Mr. PARKER exhibited a specimen bearing on the subject of tetanus. It was taken from a man who had sustained a gunshot wound in the lower part of the leg, which was deemed to be of only superficial extent, and tetanus was wholly unexpected as its result. Mr. Hutchinson stretched the sciatic nerve in vain, to give relief, and the man died. Post-mortem examination showed the wound to be a deep one, and the posterior tibial nerve and vessels were glued together by inflammatory exudation. Shot were found in the sheath of the nerve. In a second case in which death occurred from tetanus a superficial pistol wound of the thigh was supposed to exist; and in a third instance a labourer had been prodded in the leg with a pitchfork, as it was thought, superficially, but in reality so deeply as to strike the musculo-cutaneous nerve. Death occurred in this case also. In a fourth case a boy was wounded superficially over the tibial tubercle, and after death no local nerve lesion could be distinguished. Having lately examined two cases of tetanus neonatorum with cure, Mr. Parker had failed to discover any trace of septic influence to account for its occurrence, and he thought it would be highly interesting to examine the blood from subjects of tetanus with a view to the discovery of such organisms as might account for the phenomena observed.

Dr. DICKINSON said that Mr. Parker's remarks almost appeared to revive the old opinion of tetanus, which regarded it as a blood disease, and he could not but think there was a good deal to be urged in support of such a view. It always followed the existence of an open wound, and the irritation was conveyed by nerves, affecting the system through their agency. Congestion of the cord and exudations resulted from irritation set up by tetanus, and were not by any means essential parts of the disease. The pathological changes induced were, however, very important considerations. The affected side of the cord was always opposite to that of the wounded limb, and the lesions were sometimes of enormous extent, amounting even to rupture of the anterior horn. There were, also, morbid nervous conditions which the microscope was unequal to revealing at present. In his experience, the most hopeful results from treatment had been obtained from the employment of Calabar bean. In two cases he had seen marked improvements follow injection, the spasms having been immediately subdued. He had not perceived so much benefit from use of chloral. Probably, in that case, in which nerve-section had been resorted to, it was performed too late to be of service.

Mr. BARWELL said he had been sent for last November to see an old patient who had been seized with fits possessing the character of distinct trismus. His wife described a series of spasms which had been induced, and there was pain in the right leg, a small lump on the back of which could be felt, and by pressing which opisthotonos was set up. Four months previously the patient had trodden on a needle, and on cutting down upon the tumour in the leg, Mr. Barwell found and extracted a broken fragment of carpet needle, a severe fit occurring at the time. Two fits

followed subsequently within six hours, after which there were no more. Temperature and pulse both declined after the operation. In this case there was no open wound, but the needle, which had broken in the sole of the foot, had travelled up the leg, and probably pierced the nerve.

Mr. BUTLIN thought it useless to discuss one particular treatment for tetanus, which could only be regarded as a set of symptoms. In one class of cases section or stretching of nerves was useful. Some cases began with local symptoms, and ended in constitutional affection. Mr. Butlin instanced a case under the care of the late Mr. Callender, in which disorganisation of the popliteal nerve was induced by the tension set up in a limb stretched by a weight, the patient dying of spasm of the glottis, general clonic contractions having been previously set up. In such a case he said stretching or division of the nerve, or early amputation, would prove efficacious.

Mr. HOWARD MARSH urged that Calabar bean had been tried unsuccessfully in many cases, and that chloral was the remedy most generally favoured. Cases had recovered after amputation. Until Mr. Butlin could tell them the cause of tetanus, endeavours to relieve it in every possible way should be indulged. Mr. de Morgan had said he never saw a case of traumatic tetanus recover.

Special.

THE VACCINATION INQUIRY.

A COMMITTEE meeting was held on Thursday last, March 29th, in the Council Room, Exeter Hall, Strand, Dr. C. R. Drysdale in the chair. A portion of the large correspondence was read. Dr. Cresswell Rich, Secretary of the Reception Committee of the annual meeting of the British Medical Association, Liverpool, had desired to bring the vaccination inquiry to the knowledge of the profession and the public through discussion on the subject at the annual gathering. Dr. C. R. Drysdale stated he would read papers on the subject at the above annual gathering, and that of the Social Science Association. Mr. M. D. Makuna had also promised a paper for the former. The information received up to this time was ordered to be published. The Transactions of the Vaccination Inquiry, Part I., will be before the public during the first week in May, and will contain a sketch of Parliamentary history of vaccination, and the Acts; the collection of replies to the questions in the circular from nearly 390 medical men, of whom more than a hundred are public vaccinators and medical officers of health; notes and abstracts from various authors and contributors. The inquiry has been brought to the knowledge of the public and Parliament by advertisements and reports of the meeting in daily newspapers and various journals. The various Ambassadors, Consuls, Secretaries to Legations, have been made acquainted with its existence, and it is intended to request them to furnish information on the subject from different parts of the world. In the discussion, Dr. C. R. Drysdale, Dr. C. Renner, Dr. Bernard O'Connor, Dr. W. J. Collins, Dr. W. Easby, and Mr. M. D. Makuna took part. The meeting was adjourned for three months, during which time further information, principally statistics, would be collected. Contributions and papers on the subject are invited from the members of the profession.

Mr. JAMES TREVAN, F.R.C.S., has been presented with a massive silver punchbowl by the directors of the Alexandra Hotel, Hyde Park, in recognition of his medical attendance on their visitors for upwards of twenty years.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

TYPHOID FEVER.—M. Vulpian occupied the whole *séance* of the Académie de Médecine with the treatment of typhoid fever, which never seems to weary the learned professors. M. Vulpian preferred salicylic acid to sulphate of quinine. The former was not only an anti-thermic but also an anti-pyretic. He never found it to produce a deleterious action on the heart, nor arrest the albuminuria which was almost constant in a more or less degree in typhoid fever. He had particularly remarked the absence of bed sores and the absences of convalescence when salicylic acid was administered.

THE GRAVITY OF CONGENITAL HERNIA.—At the Société de Chirurgie, M. Trélat spoke on the gravity of congenital hernia, grave because they became suddenly strangulated, and that the seat of the obstruction was situated more generally in the internal and superior part of the inguinal canal; so that often the diagnosis was rendered very difficult, and serious delay was the result. It goes, without saying then, that the necessity of proving the existence of a congenital hernia is paramount. The history, the presence of a concomitant hydrocele, and, above all, the fact that the hernia draws habitually with it the testicle in its reduction, ought to remove all doubt.

THE COST OF FASHION.—The young ladies who pride themselves on the possession of little birds of every colour fixed artistically in their hats or their dresses, little think of the price at which these objects of adornment are obtained. They cost often the health, and sometimes the life of those occupied in their preparation. M. Potain has had recently in his service two patients who presented all the symptoms of consumption at the second stage. These two patients, of an otherwise good constitution, present none of those diathetic signs which precede, so frequently, phthisis, and nothing in their antecedents appeared to indicate a predisposition to a tubercular affection. One of them was a mattress maker, while the other prepared birds for the toilet. M. Potain considered that the emanations consequent upon the work of each, was the cause of the disease. Dr. Proust has written a work in which he refers to the different pulmonary affections produced by the inhalation of organic or inorganic atoms. As to the microbe of phthisis, which a few months ago caused such a stir in the medical world owing to the alleged discovery of a bacteria by Prof. Koch, of Berlin, M. Feltzy, of Nancy, is inclined to deny its existence. He made experiments similar to those of the German physiologist but obtained, in every instance, negative results.

IRREDUCIBLE LUXATION OF THE HIP-JOINT.—At the Société de Chirurgie, M. Pallaillon communicated a case of irreducible luxation of the hip-joint which had been reduced by operation, or *methode sanglante*. The patient, who was alcoholic, succumbed shortly afterwards. This operation was not practised before him more than twice—once by Volkmann in Germany, and once in England by McCormack. The first case was that of a man of fifty who had a luxation of the hip from being crushed by earth falling on him. The head of the bone was in the obturator foramen. The operation consisted in resection of the head and the upper extremity of the femur. The other case, which was much similar, as far as the abnormal position of the head of the bone was concerned, only that the subject was much younger, was submitted to the same operation by McCormack, and with an equal success. Both patients

recovered. If the case of M. Pallaillon was not so fortunate in its results, it should be taken into account that the subject was not in a favourable condition for any operation, as he was an old tippler. Before using the knife, every means were employed to reduce the dislocation, and, in spite of chloroform, all attempts failed. Bromide of potassium was given in large doses for eight days with a like result. With the concurrence of his colleagues, M. Pallaillon had recourse to the knife. An oblique incision, commencing near the anterior inferior iliac spine, and extending four inches, laid bare the fibrous envelope immediately covering the head of the femur, which was lying on the ilium, close to the edge of the cotyloid cavity. After section of the resisting tissue, the femur, by a rotatory movement, was easily restored to its primitive position. Drainage, with Lister's dressing, and immobility, constituted the rest of the operation. However, gangrene set in in the wound, and on the fourth day the patient succumbed. M. Tillaux doubted the irreducibility of the coxæ femoral articulation, for he himself has always succeeded, and thought that, if his *confrère* had practised his method, which consisted in using traction during the rotatory movement, he would not have had to open the joint. M. Anger and M. Marc Sésé coincided with M. Tillaux.

Department of Lunacy.

THE CRICHTON INSTITUTION, DUMFRIES.

THE announcement that Dr. Rutherford has been appointed Medical Superintendent of the Crichton Royal Institution at Dumfries will occasion some surprise and speculation; and will also, it is to be hoped, lead to some official inquiry into the management of the important public charity at the head of which he has been placed. Dr. Rutherford is favourably known by the manner in which he has conducted the Woodilee Asylum at Lenzie, near Glasgow, and by his antipathy to locks and keys; and no doubt need be entertained that he will prove an able and efficient chief officer of the Crichton Royal Institution at Dumfries. But still it may be argued that it would have been much more satisfactory had the appointment to which he has succeeded been advertised as vacant, and had he been elected to it after an open competition. The appointment at the Crichton Institution is a very valuable and desirable one; it is, indeed, one of the few prizes open to our brethren who are engaged in lunacy practice in Scotland. And not only is it a valuable appointment, but a highly responsible one, involving a double charge—the care of the Southern Counties Asylum, the pauper lunatic asylum of the district, and of the Crichton Institution proper, in which upwards of two hundred lunatics of the upper and middle classes are under treatment. It is, then, surely but just and reasonable that any vacancy in such an appointment should only be filled up after all the best men engaged in lunacy practice in the country have had an opportunity of applying for it, and after the claims and credentials of as many of them as offer themselves have been carefully considered. It cannot be for the interests of the institution or of the public that so important an appointment should be quietly given away by half-a-dozen small Scotch lairds met in secret conclave. The governors of the Crichton

Institution are no doubt very deserving gentlemen, but they are not, from what we have been able to learn of their antecedents and pursuits, in any way specially qualified to exercise medical patronage, by the mere light of instinct and without any extraneous advice or assistance.

The medical profession, the relations and friends of the inmates of the Crichton Institution, and the public have good ground of complaint against the governors of the Crichton Royal Institution for the manner in which they have filled up the recent vacancy; and it will perhaps appear after the inquiry which seems inevitable that they have still more grave ground of complaint against them for the manner in which that vacancy was created. Dr. Adam, who has resigned the position to which Dr. Rutherford has succeeded, was appointed to it only three years ago; and in order to accept it, he gave up the medical superintendship of the Imbecile Asylum at Caterham, which he was filling with acceptance and success. It is not understood that Dr. Adam has obtained any other appointment in lunacy; and in fact, it is broadly stated that his resignation is not really voluntary, but has been in a measure forced on him by the governors. The official announcement is that Dr. Adam, one of the assistant medical officers, and the matron have simultaneously resigned; and it is reported that the resignations of the six principal officers of the establishment were recently in the hands of the governors, who have, however, induced three of these officers to continue in their service. All this seems to demand explanation, and we should be neglecting our duty to the medical profession if we failed to call attention to it. The Crichton Institution is a great medical charity, capable of affording immense benefits to the community in the midst of which it is placed; and it would be sad indeed that its usefulness should be compromised and the welfare of its inmates jeopardised without any notice being taken of proceedings which tend towards such unhappy results. It has evidently thriven greatly under the management of Dr. Adam, as the reports of the Commissioners in Lunacy abundantly testify; and the reasons should be made public which have induced that gentleman suddenly to resign his trust, thus taking a step which he certainly did not contemplate when his last report was written. It may be that a thoroughly satisfactory explanation of the suspicious circumstances to which we have alluded can be at once supplied; but even in that case the governors will have no cause to feel aggrieved by our remarks, which are rendered necessary by what we do not hesitate to call the unwholesome secrecy in which their functions as governors are performed.

THE EAST RIDING LUNATIC ASYLUM.

THE East Riding Lunatic Asylum at Beverley, which is now under the medical care of Mr. M. D. Macleod, contained, as we gather from the official report, 283 patients on the 1st of January last, 64 having been admitted, 30 having died, and 28 having been discharged during the previous twelve months. The general character of the cases admitted was, it appears, most un-

favourable. In twelve cases there was general paralysis, epilepsy, or organic disease of the brain; in three cases there was congenital epilepsy; and in ten cases the age of the patient was above 60 years. It is not to be wondered at that, under such circumstances, the rate of recovery was low. In none of the recovered cases had the disease been of longer duration than three months at the date of admission, and in ten out of the total number insanity had existed for less than one month prior to asylum treatment being resorted to. Industrial occupation has been encouraged, exercise in the open air for those unfitted for work, and the usual means of recreation have been used. Extended liberty has been given to individuals when possible, and permission to visit their friends at home for a few days has been granted where it was thought safe and desirable to do so. Certain much-needed sanitary reforms have been introduced into the system of drainage by Dr. Macleod, who has evidently entered on his new duties with zeal and energy.

THE PLEA OF INSANITY IN CRIMINAL CASES.—CASE OF GEORGE MILLER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am not surprised at your comments on the case of George Miller, recently tried for murder at Glasgow. Notwithstanding Lord Deas's declaration at the commencement of the trial that doctors are no better judges of insanity than other people, the verdict was determined entirely by medical opinion, and yet but few of the facts on which that opinion was founded came out in the evidence. A witness-box is proverbially the worst possible place for eliciting a full medical opinion, for a witness is required to answer the questions put to him, and not to deliver a medical exposition of the case.

Your comments give me an opportunity which I willingly embrace—pending a fuller report elsewhere—of stating some of the facts on which the medical opinion was based.

Miller had apparently been during all his life subject at uncertain intervals to brief attacks of giddiness and unconsciousness, in which he would fall to the ground if he did not clutch at some support. These attacks were always worst after drinking, although they occurred independently of it.

Temporary insanity had repeatedly been induced by drinking during the seven years of his military service.

On one occasion, when under arrest in the barracks, he became so wildly violent that he had to be tied to prevent self-injury. On another, in like circumstances, he tried to cut his throat. On another, he flung himself over a bridge into the river Kelvin, at Glasgow, narrowly escaping fatal injury. On another, he suddenly assaulted a woman on the street without a shadow of provocation; and on the last occasion he committed the murder for which he was tried.

On every one of these occasions he was utterly unaware of what he had done, and only learned it afterwards from the testimony of others.

This history was known both to the prosecution and the defence; why it was not elicited in court I know not. It seems to leave no reasonable doubt that Miller was properly acquitted of murder on the ground of insanity.

His real crime was in taking drink at all when he knew the condition it had formerly produced.

I am, Sir, yours, &c.,
D. YELLOWLEES.

Glasgow Royal Asylum,
March 31, 1888.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 4, 1883.

THE MEDICAL BILL.

THE second reading of this measure is set down for Thursday next, in the House of Lords; and as it is the only public business on the paper, it is certain to be discussed. On this occasion, as on the second reading of every Bill, questions only involving the principle of the measure will be debated, the amendment of its details being deferred until the Committee stage. We regret to be obliged to anticipate a considerable opposition on the part of the licensing bodies. That the Scotch Universities and corporations should oppose, by any or every means, a measure which will prevent their continuing to bid downwards for the patronage of English and Irish students, has always been anticipated, and we assume that on Thursday the Duke of Buccleuch will appear as he did in 1879, as the opponent of the measure on behalf of Scotland. The London College of Surgeons, we regret to hear, is also contemplating open hostility to the measure, in the interest, probably, of the new-born conjoint examination scheme, in which the London College of Physicians is to co-operate. The Irish licensing bodies are divided in opinion as to the course they shall take. The University of Dublin and the King and Queen's College of Physicians, both of which institutions are largely influenced by the Rev. Dr. Haughton, have pinned their faith to the proposition embodied in Professor Huxley's postscript to the Report of the Royal Commission. The Irish College of Surgeons—though urged in the same direction—has refused to adopt

that course, and has agreed to refrain from opposing the Bill if it is promised two essential amendments, which, in equity and expediency, we think the Government need have no hesitation in granting. The Royal Irish University Senate has not yet decided upon its attitude, but it is whispered that a sub-committee was summoned to consider the question, that only two senators attended, one of them the *alter ego* of Professor Haughton, and that these two gentlemen agreed to advise the adoption of the Huxley dogma.

That two, if not three, of the Irish licensing bodies should be led to accept this proposition, and that the Irish College of Physicians should be one of these, is a notable compliment to Professor Haughton's influence in Dublin, for any proposal more destructive of the corporations and more likely to serve the Universities at their expense, and at the expense of good education, could hardly be conceived. Professor Huxley proposes—

a. That the diploma of every licensing body which examines in all the subjects—medicine, surgery, and midwifery—shall be admitted to the Register.

b. That the efficiency of these examinations should be secured by associating coadjutor examiners, appointed and paid by the Medical Council, with the examiners appointed by the licensing bodies.

Now we may look at this proposition from two points of view, that of the medical reformer, and that of the licensing corporation. We would point out, in the first place, that it would not remedy any single one of the abuses of which reformers complain. It would leave to the nineteen licensing bodies all the diploma-granting powers they now possess, subject only to such keeping up of the examination standard as might result from the presence of the coadjutor examiners. We know of how little worth the periodical visitation of examinations by Medical Council assessors has proved, and we can easily calculate the enormous cost of providing a sufficient number of paid coadjutors to sit out all the final examinations of every licensing body in the Kingdom, and we may well doubt that the game would pay for the candle. But suppose the scheme practicable and successful, what purpose would it serve? It would, in effect, substitute examination for education as a test of competency.

Each licensing body would continue to accept whatever curriculum it pleased, and would give its diploma on any terms it pleased; and thus the existing abuses of educational and monetary competition would be in nowise remedied. But regarding the subject from the point of view of the Corporation, the proposal is still more objectionable. Professor Huxley would register every diploma granted after a complete examination in medicine, surgery, and midwifery: now it happens that the Universities only are competent to hold such examinations or grant such diplomas. The Colleges of Surgeons could not obtain admission of their Licentiates to the Register without adding to their examinations such a test in medicine and therapeutics and midwifery as would satisfy the coadjutor examiners. The Colleges of Physicians could not, on the other hand, grant a single registrable diploma until they had added surgery and surgical anatomy to their examinations; and the Apothecaries' Companies would cease to exist as licensing bodies unless they constructed a

complete and exhaustive examination in all subjects. Thus each licensing body would grant a new diploma to cover the whole educational ground, and the last stage of confusion would be worse than the first.

We believe we may anticipate that Professor Huxley's views, which suit so nicely the constituents of Professors Haughton and Turner, will not be the law of the future; but it will serve their purpose as a means to defeat the present or any other Medical Reform Bill.

We hope we have said enough to show the profession that their whole strength will be needed to defeat the opposition of the licensing bodies. We most strenuously urge our readers to spare not the exercise of their best influence to strengthen the hands of Government. The Bill can be and will be improved in detail, but its principle is thoroughly sound and deserving of active support.

THE MICROCOCCUS OF MENINGITIS CEREBRO-SPINALIS.

HERE LEYDEN demonstrated this micrococcus before the Berlin Society for "Medicine" on Feb. 19. He commenced by saying that there could no longer be any doubt as to the parasitic nature of cerebro-spinal meningitis. He referred to some observations by Klebs and Ebert on meningitis following pneumonia, and stated that he himself had found in the exudation liquid of meningitis the same cocci as had been met with in pneumonia. He could likewise prove the existence of the cocci in a case of pyocephalus. Klebs had repeatedly examined the cerebro-spinal fluid in cases of pneumonia, and had drawn attention to the frequent presence of micrococci therein, and had described a case of purulent meningitis in which rapidly-moving monads were present.

The case from which he demonstrated the preparation was that of a woman, 56 years of age, who arrived in Berlin by railway on the 22nd of December last. On the journey she suffered much from emesis. On alighting she was attacked with giddiness, and fell, cutting her face. Perforation of the ear and discharge were noticed subsequently. Some days afterwards she presented herself at the Charité, suffering from inflammation of the ear, violent cephalalgia, and vomiting. The patient improved greatly under treatment. About the end of January, however, she became much worse. The headache and vomiting returned, great restlessness came on, after a few days, coma, and all the symptoms of well marked cerebro-spinal meningitis. Death occurred soon after. The section showed a diffused cerebro-spinal meningitis, with tolerably copious effusion, the otitis had completely disappeared and the perforation was closed. The case was therefore to be understood as one in which the patient before her last illness had within her the germs of the meningitis, which first attacked the ears. It was well known that acute otitis often attacked children which at first was very difficult to distinguish from meningitis. So it was here.

A great number of micrococci were found in the fresh exudative liquid, all of a perfect oval form, rather larger in the speaker's opinion than the micrococci of pneumonia, they moved with a tremulous movement, but were otherwise analogous to the cocci of pneumonia. The cocci lay

singly, two together, or in thick chains. It was noteworthy that in the present case the cocci were met with in a case of idiopathic cerebro-spinal meningitis, that they were distinct from the micrococci of pus, but that they resembled those of pneumonia, also those of erysipelas. Whilst he compared them with those of pneumonia he did not think them identical, first, because they were somewhat larger; second, their oval form was much more sharply defined; and, third, groups of two cocci were met with, one of which was small and the other large. He did not think it difficult to distinguish these micrococci from those of pus. Those of meningitis showed a peculiar tremulous movement, nothing like so lively as that exhibited by decomposition cocci.

In a contribution to the *Centralblatt f. d. Medizin-Wissenschaften* Herr Leyden draws further attention to the coincidence of the similarity in parasitic origin of the three diseases mentioned above. He says bearing in mind the similarity of the cocci of cerebro-spinal meningitis to those of pneumonia and erysipelas, it is interesting to learn that these diseases which in their anatomical form and in their course show many points of agreement are also dependent on analogous micro-parasites. Pathological anatomy has already marked the similarity between pneumonia and meningitis and erysipelas, and this before any mention had been made of their parasites. This agreement seems to me to be worthy of note, and to cause it to be borne in mind that erysipelas and pneumonia are not unfrequently associated with meningitis, whilst cerebro-spinal meningitis, even the epidemic form is not unfrequently accompanied by pneumonia.

Herr Grohé, of Mannheim, in a paper in the *Deutsche Med. Wochensch.* on "Komplikation der Pneumonia Crouposa mit Meningitis Cerebro-Spinalis" also draws attention to the subject of this association. He quotes Immermann and Heller and Maurer as reporting thirty cases of croupous pneumonia in which the association with epidemic cerebro-spinal meningitis was met with fifteen times, whilst other observers, amongst whom he mentioned Juergensen, Klebs, Rudnew, Jaffe, Rotsonopoulos, have but rarely met with the complication, and others, Fränzel, Hanuske, and others, not at all. Simple meningitis he speaks of as more rarely associated with pneumonia. He reports a case of this form of complication.

QUACKERY RAMPANT.

THOSE who are most anxious for the removal of the worst abuses of quackery in this country have naturally submitted the penal clauses of the new Medical Bill to very close inspection, and with a result not wholly encouraging to hopes of future reform. It might almost be considered possible that the extent to which the trade of quackery is carried on in this country was unknown to the framers of section 28 of the Bill, wherein the penalties to be enforced for illegal practice are defined. In this clause, indeed, there is nothing to prevent any would-be claimant to medical skill—such, for instance, as a certain "reverend" impostor, who advertises his willingness to advise, and receive money for advising, persons afflicted with aural diseases—from continuing his unholy

traffic. Provided no pretence is made to the designation of physician, surgeon, doctor, or apothecary, or to any description denoting a qualification by law to practise medicine, surgery, or midwifery, he may deceive any number of miserable victims without let or hindrance as far as any provision of the reforming Bill is concerned. It is quite easy, therefore, to see even now that no amelioration of existing evils will follow in the wake of a new Act, presuming that by some incalculable chance Parliament ever sees its way to discuss in the Lower House such an unimportant detail as the system by which the health of the people is cared for.

There are, however, at this present time, in all large cities, such hordes of quacks of the most rampant type, and the most flourishing description, that it would be well indeed could legislation be entirely devoted to their utter suppression, though a whole month were exhausted by the effort. Nor is it our own countrymen alone that find the trade so profitable and easy that they prefer its golden paths to honest labour, and gleefully pocket the scraped-up savings of their needy victims, who ultimately are compelled to have recourse to eleemosynary hospital assistance when the ravages of disease unchecked have made them pitiable objects of compassion. America contributes largely of her "citizens" to the ranks of quacks who infest this *free country*; even celestial China has sent one at least of her sons to live luxuriously in the principal medical quarter of London, whose exorbitant fees are ungrudgingly paid by persons of presumed education and of certain means. And all this tends, not only to the immeasurable disgrace of legitimate medicine, but it does more than this, for it beggars the practitioners who are robbed of patients they would willingly and skilfully treat to cure, in order that unprincipled charlatans may convert them into hopeless invalids for the sole sake of increasing their ill-gotten gains.

The plan adopted is as old as the hills, and has but one object in view—viz., money, and a constant supply of it. Any unfortunate patient who applies to one of these leeches is not long permitted to doubt the urgency of his case, but is forthwith worried and frightened into a condition of nervous prostration which more than ever conduces to his successful spoliation. At a house in Oxford Street, purporting to be a branch establishment of an American hotel whose proprietor combines medical treatment with boarding and lodging, we have reason to believe that large sums are annually obtained from confiding invalids in the expectation of some miraculous cure. At the delectable institution in question the sacred calling of medicine is degraded to the very lowest depths; and not content with selling nostrums and secret preparations, the "Association" even proceeds to such doubtful extremities as trading on the ignorant fears of its dupes, in a way that is at once loathsome and disgusting. We have in our possession a number of the documents issued by the Association, and from them it is clear that a regular system is carried on, different forms being employed in different cases, but all tending to one end—money. As a sample of the honourable nature of this trader's dealings, the following letter, received by a patient who was fortu-

nately wise enough to show it to a medical man before attending to it further, will suffice:—

Dear Sir,—Yours to hand, and contents noted. In view of the importance of your having continuous treatment *now*, we have decided to offer you our treatment hereafter, at 15s. per month. We believe that you can *now* be restored; but if you neglect yourself, or go without proper attention at this particular time, we will not vouch for the consequences. Your case was examined and prescribed for by an English M.R.C.S. We do not publish the names of physicians connected with our establishment. Hoping to hear from you by an early post, and be the means of restoring you to health, we remain

Yours very truly.

The precious epistle was signed, in place of the name naturally to be expected from a medical man, with a stamped impression of the "Association" title, and the monogram "B." What can be the worth of "an English M.R.C.S." whose name cannot be published, we need hardly stop to inquire; probably as great as the snivelling hypocrisy of the hope to "be the means of restoring you to health," for fifteen shillings per month, with which the letter concludes. In England it is usual for medical men to have the courage of any opinion they may give, and to be fearlessly prepared to maintain it. If the "Association's" secret mode of proceeding is a reflection of American custom in this particular, then we should be sorry indeed to see any very general imitation of it here. But we do not believe anything of the kind. We believe that American physicians would be as quick as we are to repudiate and reprobate the action of a man or of men who can so deliberately insult the profession of medicine as is done by this so-called "Association." And, further, we feel assured that unless the "English M.R.C.S." is a very unworthy holder of that title he is entirely ignorant of the questionable proceedings to which he is made to appear a consenting party; as he must be if the honour of his profession is of any interest to him.

We had intended to say much more on this subject, but for the present what we have said must suffice; it may serve, however, to show what urgent need there is for stringent legislation if the new Bill is to have any effect in repressing quackery.

Notes on Current Topics.

"Fort Mit Dem Spray."

TIME does not in any way tend to reduce the feeling of disfavour with which employment of the spray is regarded on many hands, and on Friday evening Mr. Christopher Heath dealt another and by no means insignificant blow at the same adjunct to antiseptic surgery. To the cooling effects produced by the spray during performance of an ordinary operation Mr. Heath unhesitatingly ascribed a very considerable part of the fatal consequences which frequently follow in such cases; nor can we feel any great surprise that such a conclusion should be entertained. It is reasonable to assume that exposure of a wounded surface for the space of half-an-hour or more to conditions such

as are set up by a vaporous surrounding of the part, and constant liquefaction of steam, must be provocative of most injurious consequences by reducing local temperature. But there is a still graver charge preferable in the same connection against the spray—that, namely, it leads to absorption of carbolic acid in poisonous quantities, and so brings about one of the principal evils associated with antiseptic surgery, according to strict Listerism. The failure to detect carboloria after such operations may, as Mr. Heath pointed out, possess the utmost significance; for when the kidney does not excrete the poison, it remains to do its deadly work in the system. It may be pointed out here that it is taken for granted that carbolic poisoning ensues as a necessary consequence of using the spray—a conclusion that would seem to receive very general adoption, since quite a large proportion of strictly antiseptic operators are avoiding the dangers incurred by its employment. Dr. Andrew Clark, President of the Clinical Society, probably expressed the opinion of the profession when, after Mr. Heath's remarks on Friday, he uttered the hope that the speaker would take an early opportunity of expounding the views he had briefly drawn attention to. The subject is of such importance that we hope Mr. Heath may speedily accept the friendly challenge thrown down to him.

Astley Cooper Prize.

THE Astley Cooper prize, which consists of three hundred pounds, and is awarded but once in three years, will be next competed for in 1886. The subject of the essays is "Diseases and Injuries of the Nerves and their Surgical Treatment, together with the operations performed upon nerve trunks in the treatment of various diseases, and the descriptions of the changes which ensue in other structures, as well as the nerves themselves from these operations." It is essential that preparations and drawings (original) illustrating the text of the treatise shall accompany it, and the whole must be delivered at Guy's Hospital, addressed to the physicians and surgeons of that institution, on or before Jan. 1st, 1886. Each essay or treatise must be accompanied by a sealed envelope containing the name of the writer, and endorsed with a motto corresponding with one by which the essay itself must be alone distinguished. Unsuccessful essays may be claimed by the writers or their agents, and will be known only by the mottoes attached to them, as the envelope corresponding to the successful motto is the only one that will be opened. The prize is open to the whole world, with the exception of physicians, surgeons, and other officers for the time being of Guy's or St. Thomas's Hospitals, and of blood relations of these officials. Essays, save such as are written in English, must be accompanied by a translation in that language.

More Peculiarity.

LESS than two months ago we had to refer to a case of child death in connection with which a coroner's jury returned a verdict of manslaughter against the father, Robert Cousins, a "peculiar" person. The charge, it will be remembered, was dismissed by the magistrate, and now that which we declared had to be feared has come about. Another child of Mr. Cousins' has paid the debt of

nature at the age of eleven months, and without the assistance of any medical man having been invoked in its behalf. This time also, Mr. J. F. Payne, coroner for Southwark has held an inquest on the unfortunate descendant of a "peculiar" father, with a repetition of the former result, viz., a verdict of manslaughter. If the same lenient treatment is experienced by Mr. Cousins in the police court as he met with before, then he may be expected to congratulate himself more than ever on the remarkable immunity "peculiarity" confers on those who are expressly declared by a jury of their peers to have been guilty of negligence resulting in death of the neglected victim. This is no place to enter on the revolting disclosures of stolid indifference shown to a dying child by those who should have been warned to make every effort in its behalf by the painful consequences of their former heartlessness. The plea of religion is a mockery in such cases, and it remains only to wait for a magistrate's opinion of the matter.

The Irish Medical Benevolent Fund.

WE learn with much satisfaction that the late Dr. John Wilkinson, of Limerick, has bequeathed the sum of £1,000 to the Royal Medical Benevolent Fund Society of Ireland.

The Poison of Ergot.

IN a recent communication read before the Chemical Society of Russia, the author, A. W. Pehl, attributes the toxic properties of ergot to putrefactive changes set up during decomposition of the vegetable fibrin of the wheat. The poisonous products of putrefaction, denominated ptomaines, are due to the peptic action of the ergot, which is exerted to a very considerable extent, and so contributes to the splitting up of the elements of flour and their subsequent putrescence.

A Prescribing Druggist.

AN inquest was recently held at Blackley, Lancashire, by the County Coroner, on the body of Esther Alice Sparke, æt. 19, wife of a clerk, who had died in the course of a puerperal fever. The medical officer of the sanitary authority drew attention to the fact that out of seven similar cases attended by a certain midwife four had terminated fatally. In the course of the inquest, one Jackson, chemist and druggist, said he was sent for to attend the deceased on the previous Thursday. He left a bottle of medicine, and visited her again, and repeated the medicine as before. He did not make any examination, and did not take the temperature. He had asked "another medical man" to go with him to see the case, but he refused, saying that his patients might object. The Coroner: I cannot conceive that a gentleman would go with another man who is unregistered. Witness: I will find you half a dozen if you wish it. The jury returned a verdict of death from puerperal fever, accelerated by want of skilled medical attendance. Addressing Mr. Jackson, the Coroner said: The jury have hesitated to pass a vote of censure upon you, but they have expressed the opinion that you did not attend the woman as frequently as the case required. You have

shown great ignorance of the profession in not taking the temperature of the body or making local application. I am going to caution you myself—I do not care what the jury do—but if another case comes before me as coroner in which you are implicated, I shall certainly advise the jury to send you to the assizes for manslaughter. I do not think you are at all capable of taking care of such cases.

The Mode of Administration of Santonin.

HERR L. LEWIN, in a recent paper on the above subject, read before the Medical Society of Berlin, finds fault with all the usual methods of administering santonin. According to his views, it should be given in its least soluble form, *i.e.*, in that form in which it will be the least readily absorbed, as the effect desired is not a general, but a local one. An oily solution of santonin undergoes, according to his experiments performed on animals, not the slightest absorption in the stomach, so that under no circumstances is any trace found in the urine. Almost any kind of oil may be employed, cocoa-nut oil, olive oil, cod liver oil, or castor oil. He recommends that 0.2 grm. (3 grs.) of santonin be mixed with 60 grm. (2 oz. *cir.*) of oil and given in four doses. He thinks that a useful addition to the above would be that of an oil contained in santonica, the *oleum cinæ æther.*, for the reason that all æthereal oils have been shown to act as poisons on the lower forms of animal life.

Pasteur and Koch.

A SHORT time ago (January 17th) we gave our readers a *résumé* of Koch's reply to the attack made upon him by Pasteur at the Hygienic Congress held at Geneva during the autumn of last year. In answer to the charge of the former, that he (Pasteur) presented nothing scientifically new at the Congress, he points to the common method of diminishing the power of virus by the simple action of atmospheric oxygen, the publication of new microbia, investigations into the conditions under which their virulence is lessened, &c. He denies having spoken of a new form of rabies, and asserts that he only spoke of having discovered a new disease which for the first time had been produced by inoculation with saliva from a child dead of rabies; that a microbe had been discovered and described; that it had, however, no relation to the etiology of the disease, but was to be met with in the mouths of children dead of other diseases, and also in the saliva of perfectly healthy adults. He acknowledges having in the year 1877 made known to the Academy of Sciences the results of Koch's labours on the *bacillus anthracis*, but charges Koch with employing knowledge gained from his (Pasteur's) labours on the silkworm (1869-70) without acknowledgment, in order that he should not be obliged to confess that his studies on the *bacillus anthracis* were but a development of principles firmly laid down by himself. "It is not you, Sir, who have discovered the mode of generation of bacilli and vibriones by spores; it is not you who have demonstrated their special mode of formation; it is not you who have recognised their existence in the form of dust, and the long duration of their faculty of living. The accuracy with which I have described and figured these cysts, germ corpuscles, and

spores is such that you might have limited yourself to an extract from the plate on page 223 of my work, embodying it in your communication of 1876, and using it as an illustration of what you there say of the *bacillus anthracis*." He claims that it was himself who first practised "pure" cultivation of microbia; that all inquirers have acknowledged his initiative in regard to etiology; and that even Koch himself must confess himself a debtor to French science. He predicts a much more successful future to animal inoculation than Koch does, and points to statics from the Department Eure-et-Loire as a justification of his prediction.

Dr. Macnaughton Jones.

THE quarterly dinner of the South of Ireland Branch of the British Medical Association was specially held on St. Patrick's night, to bid farewell to Dr. Macnaughton Jones, on the occasion of his leaving Cork, Dr. N. J. Hobart in the chair (in the unavoidable absence of the President, Dr. Ringrose Atkins); Dr. J. G. Curtis in the vice-chair. Dr. Jones was the guest of the evening. After the usual loyal toasts, the Chairman proposed, in happy and complimentary terms, the health of Dr. Jones, which was drunk with great enthusiasm, after which the Secretary read the address presented by the Branch. The members of this Branch, together with the members of the City and County of Cork Medical and Surgical Society, presented Dr. Jones with a full-length oil portrait of himself, by Bannan.

A special meeting of the County and City of Cork Medical and Surgical Society was held on Wednesday, March 21st, to present Dr. H. M. Jones with an address. Dr. C. A. Harvey, President, occupied the chair. A large number of members was present. Dr. C. Y. Pearson, Hon. Sec., read the address, as follows:—

"DEAR DR. JONES,—We, the members of the County and City of Cork Medical and Surgical Association, having learned that you are about to leave the city where you have so long and so earnestly laboured in the practice of your profession, both in private and in many public institutions, cannot allow our connection with you to terminate without expressing our regret at your departure from amongst us, and from the scene of your former labours, to a more extended sphere of duty, where we hope your zeal and ability will meet with their due reward.—We remain, on behalf of the members of the Association, yours faithfully, Chas. A. Harvey, B.A., M.D., President; J. P. Golding, M.D., Vice-President; T. Gelston Atkins, B.A., M.D., Treasurer; C. Yelverton Pearson, M.D., Hon. Sec."

Dr. Jones having suitably replied, the proceedings terminated.

THE annual rates of mortality in the principal large towns, per 1,000 of their population, were:—Edinburgh 17, Derby 18, Bradford 19, Salford, Bristol 20, Huddersfield 21, Cardiff, Birmingham, Oldham 23, Leicester, Brighton, London 24, Preston 26, Portsmouth, Leeds, Wolverhampton, Halifax, Newcastle-on-Tyne 27, Nottingham, Bolton, Sheffield, Sunderland 28, Blackburn, Plymouth, Manchester 30, Birkenhead 31, Norwich, Liverpool, Hull 32, Glasgow 36, Dublin 40.

The St. John Ambulance Association in Egypt.

At a meeting of the Central Executive Committee, held on Friday last, at St. John's Gate, Clerkenwell, Colonel Sir Henry Loch, K.C.B., Commissioner of Woods and Forests, in the chair, it was reported that at a recent inspection of the Egyptian artillery at Cairo by General Sir Evelyn Wood, the men went through a demonstration of the stretcher drill of the St. John Ambulance Association, which had been introduced by the Commanding Officer, Colonel F. Duncan, R.A. Deputy Chairman of the Association. The demonstration was subsequently repeated in the presence of the Khedive, who expressed himself as greatly pleased with the men's progress.

The students at the Bristol School of Medicine have presented Dr. Evans, their medical tutor, with an address and several volumes of works, on his appointment of House-Physician to the Royal Infirmary.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 33, Bombay 35, Madras 34, Paris 30, Geneva 19, Brussels 27, Amsterdam 26, Rotterdam 28, The Hague 30, Copenhagen 27, Stockholm 27, Christiania 18, St. Petersburg 42, Berlin 22, Hamburg (State) 24, Dresden 23, Breslau 28, Munich 34, Vienna 33, Prague 41, Buda-Pesth 31, Trieste 33, Rome 32, Turin 31, Venice 36, Lisbon 34, New York 29, Brooklyn 23, Philadelphia 23, Baltimore 21.

The mortality from diseases of the zymotic class was low last week in all the large towns. The highest death-rates from whooping-cough were 1.5 in Bolton and 4.4 in Hull; from scarlet fever, 1.6 in Sheffield and 2.1 in Leeds; from measles, 1.2 in Norwich; and from "fever," 1.2 both in Birkenhead and in Cardiff, and 1.3 in Sunderland. The 34 deaths from diphtheria included 14 in London, 10 in Glasgow, 3 in Edinburgh, and 2 both in Portsmouth and in Oldham. Small-pox caused 3 deaths in London, 4 in Newcastle-upon-Tyne, and one in Leeds.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

EDINBURGH UNIVERSITY — CLOSE OF THE MEDICAL CLASSES.—The medical classes in the University met on Friday last for the last time in the winter session, and the usual class prizes, honours, and certificates were distributed. In the class of Surgery, Professor Chiene thanked the students for the manner in which they had received him in his first session, and announced that the Building Committee had promised, before next winter session, to rearrange his class-room. In order to accommodate the large numbers who had joined the class in the session just closed, Professor Turner had kindly placed the anatomy theatre at his disposal, as the surgery theatre had proved much too small for the class. The Committee, also, were having a theatre put up in the Practical Room in order to the better carrying out of the work of the Operative Surgery Class, which would be opened in the ensuing summer session.

DEATH OF DR. REID, OF ELLON.—Dr. Reid, of Ellon, one of the best known and most respected medical practitioners in the north of Scotland, died suddenly from apoplexy on the 26th ult. He had been in practice for nearly 40 years. One of his sons occupies the position of household physician to the Queen.

GLASGOW EAR HOSPITAL.—The annual general meeting of the supporters of the Glasgow Hospital and Dispensary for the Diseases of the Ear (which owed its existence to the efforts of Dr. Cassells) was held in the hospital premises on the 26th ult., Mr. Charles M. King presiding. The Secretary read the annual report, which showed that since the opening of the hospital in 1880, 8,608 cases had been treated. The number of patients had steadily increased, last year there having been 835 new patients, as compared with 789 in the previous year, or an increase of nearly 6 per cent. Thirty-nine patients were operated upon under chloroform, and received subsequent treatment in the wards of the hospital, and 12 operations were performed without the aid of chloroform on outdoor patients. The results of the treatment had been as follows:—667 cured, 82 improved, 17 incurable (including 10 deaf-mute children), 39 not treated, and 30 under treatment. Of the total number (835), 530 were males and 305 females.

THE WATSON PRIZE AT THE FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At a meeting of the trustees of the Dr. James Watson Prize Fund, held on the 24th ult., the prize of £50 was adjudicated to Dr. William McEwen, Surgeon to the Glasgow Royal Infirmary, for the best essay on a surgical subject. The prize is open for competition to Fellows and Licentiates of the Faculty.

GLASGOW DISPENSARY FOR SKIN DISEASES.—The twenty-second annual meeting of the subscribers to the Glasgow Dispensary for Skin Diseases was held on the 30th ult., Mr. A. Orr Ewing, M.P., in the chair. Professor McCall Anderson read the medical report for the year, which stated that there had been a progressive increase in the number of new cases during the last three years—viz., 1,192 in 1880, 1,297 in 1881, and 1,517 in 1882; while the total number treated since the foundation of the institution has been 25,865. The majority of these were serious cases, which could not have been satisfactorily treated by means of outdoor relief. The total number treated in these wards since they were opened has been 664.

ANDERSON'S COLLEGE, GLASGOW.—The winter session of Anderson's College, Glasgow, was concluded on the 30th ult. by the presentation of prizes and certificates to the students. Mr. Alexander Whitelaw occupied the chair, in the absence of the President, Mr. J. L. K. Jamieson. There was a large attendance of students, whose behaviour on the occasion was not commendable. The Professors in the various classes distributed the prizes, and spoke approvingly of the progress made by the students under their charge. According to Dr. Morton, the attendance of students is as great as ever.

THE SANITARY PROTECTION ASSOCIATION OF EDINBURGH.—This Association—the name of which reminds us of a 'Society for the Protection of Policemen'—held its sixth annual meeting on the 25th ult., in the Royal Hotel, Princes Street, Edinburgh. Professor Douglas MacLagan, M.D., occupied the chair. The secretary read the report of the Council for the past year, of which the following is a brief *résumé*:—The ordinary subscribers number 483, the extraordinary 100. The total receipts for the year have been £808 1s., as against £622 13s. for the previous year. 612 inspections have been made in the course of the year.

About one hundred country houses have been inspected and reported upon, and among them 90 per cent. were found to have direct communication existing between their drains and the interior of the house; 80 per cent. had their water storage arrangements more or less faulty; and no less than 15 per cent. had the main cisterns in direct connection with large built cesspools filled with putrefying filth.

HEALTH OF EDINBURGH.—The mortality in Edinburgh during the week ending with Saturday, the 24th ult., was 71, and the death-rate 16 per 1,000. This, considering the extremely cold weather, must be regarded as a low death-rate. Diseases of the chest accounted for 40 deaths, and zymotic causes for 5, of which 1 was due to diphtheria and 1 to scarlatina—the intimations of these diseases for the week being 1 and 24.

MEDICINE AT BARNHILL POORHOUSE.—At a meeting of the Barney Parochial Board, held on the 26th ult., considerable discussion arose as to the amount of medicine supplied to the patients in Barnhill, Mr. Currie (a druggist) contending that there was far too much medicine given, and in this he was supported by Dr. T. D. Buchanan. Several members deprecated this attack on the conduct of the medical officer and his mode of treatment. If it be correct as stated by Mr. Currie, that the amount thus administered exceeds that given at the Royal Infirmary, Glasgow, surely there must be excessive drugging at Barnhill.

Correspondence.

THE ACTION OF SEDATIVES AND STIMULANTS ON NERVES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I had supposed that the function of the vagus nerve was to inhibit the action of the heart; that a current of electricity was a stimulus to a nerve; and that atropia prevented the inhibitive action of the vagus from taking place. I was therefore "thrown all of a heap" when I read the following sentence in Dr. Owen Thomas's very interesting paper "On the Action of Sedatives and Stimulants" (*Medical Press*, March 21st, 28th):—"The heart's action is always accelerated by belladonna from its primary affinity for, and stimulating effect on, the vagus nerve, which nerve this drug can protect from the collapse arising from mechanical irritation." Evidently the writer regards the vagus as the source of power to the heart, and that the action of electricity or mechanical irritation is not of the nature of a stimulus, but the reverse. I suppose he does not believe in the inhibitory action of nerves at all! Would he discuss the subject more fully as he goes on?

As to its requiring toxic doses of atropia to cause retention of urine, I have again and again found in experimenting with it personally that about a milligramme taken by the mouth will produce great slowness and difficulty in micturition, the only other physiological effect being dryness of the mouth.

Yours, &c.,
A. W. W.

THE MEDICAL BILLS AND MEDICAL TITLES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I see that after the passing of the Bill to amend the Medical Acts, it will be penal for anyone to use any medical title which he is not credited with on the Register. This will act harshly on those who, like myself, were induced to take the L.R.C.P. Ed. some fifteen or twenty years ago, believing it to be the title of doctor. When I was admitted a licentiate I was styled "Doctor" by the College, and addressed as "Doctor" in all written communications by the College, and have always called myself Doctor, since some five years ago I received the College List addressed L.R.C.P. Ed. Esq., this was the first intimation I received that the College had

obtained my money under false pretences. There are some thousand men in the same boat with myself, and I do not see what we are to do, as we were admitted to a *pseudo* doctorate as it now appears. The Royal College having grabbed our money quietly turns round after ten years and says you are no doctors. I should never have gone for the L.R.C.P. Ed. did I not believe it was a doctorate, and in that belief I was kept by the College authorities for ten years. Now, Sir, not to put too fine a point on it, have not I been done out of my time and money? Does not a Royal College who are guilty of such conduct richly deserve to be removed from schedule A? Unless the College take some steps to indemnify those who they called and admitted doctors from 1860 to 1878 (or thereabouts), I shall for one do all I can to cause the said Royal College to be disestablished as a corporation, and I now through your columns invite all those who are in the same category as I am to write to their parliamentary representatives, and urge on them to do all in their power to punish the Royal College for thus inducing men to seek its diplomas under false pretences, and then turn round and unblushingly say "you're sold, and we have got the money," for such is, in reality, what they have done. The only amends the College can make is to confer their membership on all those whom they called and induced to call themselves doctors, and then in after years said you are no doctors.

I am, &c.,
L.R.C.P. Ed.

SALICIN IN RHEUMATIC FEVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Since the publication of my letter of the 22nd ult., in which I advocated up to forty grain doses of salicin every hour (in severe cases) until the articular pain was removed, the question has been frequently put to me whether such quantities were not perilous. I have accordingly made a therapeutic investigation in the patient whose case was described in that letter (Catherine O., No. 8, St. Bridget's ward) as to what quantity of salicin could be borne without toxic or even unpleasant effects. The experiments were commenced on the 14th day of March, when this patient (a strong healthy woman of 42), was quite convalescent, up every afternoon, and taking 30 grains of salicin once a day to prevent relapse. I directed the dose to be increased by five grains every day, commencing with 35 grains on the 15th, and so on. Thus, upon the Saturday before Easter she took *eighty grains* at one dose, and that without a shadow of inconvenience. She took the same on Easter Sunday, Monday, and Tuesday, and, as this dose was entirely beyond anything that I have ever seen required in the severest cases of rheumatic fever, I did not consider it necessary to pursue the research further. The only precaution which I have found necessary in administering salicin is to give it about an hour before meals; if taken on a full stomach it sometimes occasions nausea and tinnitus. This observation need only be made in regard to convalescents; as the meals in acute cases represent a vanishing quantity.

I am, Sir, yours, &c.,

F. J. B. QUINLAN,
Physician to St. Vincent's Hospital.

29 Lower Fitzwilliam Street, Dublin,
29th March, 1883.

TRANSFUSION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—After the report (a) of two fatal cases of hæmorrhage where the intravenous injection of fluid had been employed, in the London Hospital Maternity Charity, Dr. Herman remarks that "the attention of the profession has recently been called (by some correspondence in the *Lancet*, and also by a communication to the Obstetrical Society of London) to the intravenous injection of saline fluids as a means of saving life endangered by hæmorrhage."

As this statement clearly refers to papers (b) written by myself, I must point out a misapprehension of my views—which, in case No. 2, has evidently led to a fatal result—for, whilst advocating the method in question as a means of com-

(a) *Medical Times and Gazette*, March 17th, p. 293.

(b) Cf. *Medical Press and Circular*, January 1882, p. 4; and *Lancet*, 1882, vol. ii., pp. 486, 485.

bating acute anæmia, I have never made the unqualified assertion that it would save life endangered by hæmorrhage—unless the active cause of such hæmorrhage be simultaneously removed. Nor can Dr. Herman show that either myself or other correspondent on transfusion has said one word which would warrant a woman being permitted to pass into her grave without some more recognised and more determined means being employed to effect delivery than were here adopted.

Surely it has occurred to the minds of all practitioners who have read Dr. Herman's paper that in this case the mother was allowed to perish from concealed hæmorrhage (as proved by the autopsy), augmented by abundant transfusions and heroic stimulation! The chief value of this case lies in its unique character—unique in two respects:—First, that with hæmorrhage so profound the os uteri should have remained rigid to the last; and secondly, that in the year 1882, chloroform, as a means for its relaxation, should have been withheld! Granting that delivery *per vias naturales* was impracticable (of which proof is lacking), why was the patient abandoned for those two hours, and both mother and child deprived of that chance which the Cæsarian operation would have afforded them?

Had chloroform been employed at the outset, dilatation of the cervix, either with Barnes's hydrostatic bags, or with the operator's fingers, would have been easy. The membranes ruptured, a fetal leg could have been readily drawn down into the vagina, and the liquor amnii, with the blood poured out from the placental site, would have entirely escaped from the uterine cavity. The body of the child would now have formed a most efficient tampon, against which the uterus might have been stimulated to contraction, the hæmorrhage thereby being arrested. If, at this juncture, in the opinion of the accoucheur, the loss of blood had been such that the patient's life was in peril, then the intravenous injection of fluid would, as experience proves, be attended with the happiest results.

The only parallel to the case reported would be that of an amputation where transfusion had been performed for hæmorrhage, all the arteries of the stump being left untied!

With regard to the first case—that of the placental pyæus—whilst I strongly endorse the aphorism that in post-partum, as in other hæmorrhages, the flow of blood must always be arrested before resorting to transfusion, I have pointed out (a) that the local employment of iron solutions for that purpose is most dangerous. Here there was no autopsy; and whilst the casual reader of the record might infer, from the description given, that the transfusions were useless, it is possible and very probable that embolism (produced by the perchloride of iron) was the true cause of death.

I am, &c.,

C. EGERTON JENNINGS,
Late House-Physician and Resident
Accoucheur, London Hospital.

ABUSES IN MEDICAL PRACTICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I addressed a letter on the above subject to the Editor of the *British Medical Journal*, about a fortnight ago, informing him that, when the Medical Amendment Bill was receiving consideration from Parliament and the authorities, it was a fit case illustrating the evils of unqualified practice. Strange to say, probably owing to pressure from other quarters, the letter was not inserted, and to your well-known fearlessness and impartiality I now appeal. An M.R.C.P. Edin., M.R.C.S. Eng., holding several club and local appointments at the East-end of London, conducts a practice which not only calls forth censure, but active legal proceedings. He keeps a chemist's and druggist's shop, managed by an unqualified dispenser. This man also prescribes and signs club and other certificates in the name of the principal. He also keeps a permanent unqualified assistant, who has been a dispenser and assistant for nearly sixteen years. They both pass as "doctors" among patients, who are poor and ignorant. The unqualified man does the practice of a fully-qualified one—prescribing, visiting, midwifery (including forceps), turning, &c., and signs certificates in the name of the principal. The principal does not reside on the premises, but does the business of a medical man and druggist during the day, signs now

and then death certificates without seeing cases, and vaccination certificates without doing the operation or inspecting the children. As it is *not in his interest* to keep a qualified man permanently, he keeps one for a few months, contrives to bring about a dispute among the qualified and the unqualified, making it so intolerable for the qualified that no medical man of the slightest self-respect can make a lengthened stay.

Under these circumstances I request to know through your columns—Is a M.R.C.P. Edin. allowed to keep a druggist's shop, selling penny nostrums and patent medicines? Is there any kind of supervision exercised by the authorities to analyse from time to time questionable drugs sold by such men? As for the question of illegal and disreputable practice, I should like to elicit the opinion of the profession, and see the party dealt with by law.

I remain, yours faithfully,

MONTAGUE D. MAKUNA,
L.R.C.P. Lond., M.R.C.S. Eng.

26 Charing Cross, S.W., 31st March, 1883.

[In reply to our correspondent's queries, we may say that there is at present no law to prevent a medical man keeping an open drug shop, and selling what he chooses; neither do the authorities trouble themselves to analyse the contents of such an establishment. We deplore the facts mentioned, but unfortunately such examples are legion in poor neighbourhoods.—ED. M. P. & C.]

DR. LIONEL A. WEATHERLY, Portishead, Somerset, has received a third grant from the Local Government Board for efficient vaccination.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE TREATMENT OF ASCITES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Kindly inform me through the *Medical Press and Circular* the following:—

In a case of ascites requiring repeated tapping is it advisable to introduce the trocar at the same point each time, or at a different point? If 20 grs. of chloral hyd. will not produce sleep, what is the largest dose you would advise?

I am, Sir, yours, &c.,

B. C. T.

[Should your case of ascites require frequent tapping begin on the linea alba, about two inches below the umbilicus. Upon the next occasion try an inch lower, and so on, until you approach the vesical region. Of course, you will always take care that the bladder is empty previous to tapping; and do not imagine this to be a superfluous warning, for the accident once happened in the hands of no less a personage than the illustrious John Hunter. When you have gone as far downwards as may be prudent begin again at the top, avoiding, however, the exact same spot. Abdominal tapping is seldom required so often as this; but an instance is recorded of a patient who was tapped no fewer than sixty-two times. With regard to hydrate of chloral, 20 grains is a fair dose, and will generally succeed if backed with 30 grains of potassium bromide. This latter salt can hardly, *per se*, be called an hypnotic, but is a powerful sedative and adjuvant to chloral. The injurious property of the latter is its lowering cardiac action; and the combination which we have suggested will produce the effect of 30 grains of chloral without cardiac depression. The best formula is: ℞ Chloral hydratis, gr. xx.; potassii bromidi, gr. xxx.; aquæ ad, ℥j.; syrupi aurantii, ʒi. M. Fiat haustus. H. s. s. The dose of chloral may be increased, if absolutely necessary, by 5 or 10 grains over this formula, with a corresponding increase of the bromide, and a slight expansion of the vehicle. If chloral does not suit, our correspondent might try Paraldehyde—a new remedy, which is stated by its advocates to have all the virtues of chloral without any of its drawbacks. We have as yet no practical experience of its action. Finally, we may observe that, while with some individuals chloral scarcely ever loses its effects, too often tolerance occurs; and the drug has first to be increased and then given up.—ED.]

A CASE FOR THE BENEVOLENT.

WE desire to direct the attention of our benevolent brethren to a very deserving case. We refer to that of Mr. E. Poyntz, son of the late Dr. Poyntz, Ballinasloe, whose connection with the Apothecaries' Hall as head for many years of the compounding departments, where his obliging and gentlemanly demeanour made him widely respected by the profession and public at large. Owing to a series of domestic reverses, his exertions to qualify himself have proved abortive whilst occupying the above post, and which he had recently to relinquish from bad health. Some months ago Mr. Poyntz contracted a severe and prolonged fever, which has unfortunately left behind considerable pulmonary mischief. His medical adviser has consequently strongly urged him to seek a more congenial climate, and has ordered him to Colorado. As, however, often unfortunately happens, the *res angusta domi* stands in the way, his long sickness having left him absolutely destitute. From £30 to £40 would be amply sufficient to take him to Colorado; and we appeal with confidence to a profession that never turns a deaf ear to the voice of distress to make up this small sum. We cheerfully open our columns for this purpose; and we venture respectfully to suggest to the committee of that admirable charity to which every medical man ought to subscribe—the Medical Benevolent Fund—that this is a case eminently deserving of their consideration. The following gentlemen have also kindly consented to receive subscriptions:—

Dr. MACSWINEY, 38 York Street.
Dr. KILGARIFF, 30 Harcourt Street.
Dr. KENNY, 15 Rutland Square.
And Dr. JACOB, *Medical Press*.

And reference can be made to Dr. HERRICK.—No. The Bill will have to pass through the House of Commons also; and the state of domestic legislation just now does not afford the most encouraging prospect of speedy success.

A. T. E.—The number of appointments to the Services is not proportioned to the number of qualified candidates, but to the vacancies which exist.

F.R.C.S. (Liverpool).—An account of deviation of the nasal septum requiring surgical interference may be seen in the *Bartholomew's Hospital Reports* for 1882. The nasal septum is very rarely central, as may be recognised by closing first one nostril and then the other, at the same time breathing forcibly; but, as a rule, no treatment can be adopted with any great advantage. In the five cases treated by Mr. Walsham, the symptoms were—inability to breathe through the affected nostril, nasal intonation; dull pain in frontal sinuses. Forcible straightening succeeded completely in two cases, partially in one, in restoring respiration through the obstructed nostril. A subcutaneous stellar division of the septal cartilage in addition to forcible straightening was resorted to in the two remaining cases, in both of which it was successful, but was followed in one case by a permanent perforation, which, however, was not attended by any special inconvenience.

A SEARCHER AFTER TRUTH.—From personal knowledge we cannot answer your queries; but according to a recent paper of Mr. Brindley James, homeopathic practitioners now number 260 in the United Kingdom: of these 244 are located in England and Wales; 12 in Scotland; and only 4 in Ireland. Comparing these with the number of qualified practitioners in the 1883 "Medical Directory," at 19,447, we find the proportion of homeopaths among them to be: in England and Wales, 1 in 64; in Scotland, 1 in 170; in Ireland, 1 in 609. Of course, the majority of homeopaths are found in the large towns. Thus, London boasts of 85: Liverpool, 11; Birmingham, Brighton, and Manchester, 8 each; Bournemouth, Bristol (with Clifton), Edinburgh, and Glasgow, 6 each; Torquay, 4; Tunbridge Wells, Hastings (with St. Leonards), Leeds, and Dublin, each 3; and Sheffield, 2.

M. F.—The anatomical reason why dislocation of the hip-joint forwards is so much rarer than dislocation backwards is found in the greater strength of the ligamentous structures in front of the articulation. Behind, the posterior portion of the capsular ligament, which is thin, alone prevents the head of the bone, when violently displaced, from passing backwards, while anteriorly the assistance of the ilio-femoral band materially tends to reduce the chances of dislocation in this direction.

DB. MATTHEWS DUNCAN'S LECTURES ON STERILITY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In his interesting lectures now appearing in the *Medical Press*, Dr. Matthews Duncan quotes the astounding statement (March 28th, p. 267) that "the domestic hen, in its first year, according to Geyelin, produces only from fifteen to twenty eggs." The "statement" is utterly untrustworthy, or relating to a very different kind of poultry from what we are accustomed to see in this country. I have four pullets, hatched 7th last May, and are consequently now nearly eleven months old, which began to lay on the 29th of December last, and up to the present time have produced 168 eggs, or exactly forty-two each. They are still laying, and I expect will produce a good many more eggs by the time they have completed their first year of life. My birds are kept in a small enclosed run, fed on corn and house scraps; three of them are white-crested black Polish, and the fourth is a half-bred game. I may add that the numbers given above have been entered in a book carefully day by day, and have been much exceeded by fowls in the possession of others.

I am, &c.

W. T. GREENE, M.D., F.Z.S.

Moirs House, Peckham.

HENRY FISHER.—Such a proceeding would be the reverse of wise. Before taking any action whatever consult a competent solicitor, and be guided entirely by his decision.

A PERPLEXED STUDENT.—We cannot advise you unless you state the case much more clearly than your letter explains it. You are very possibly labouring under a misconception, which a little timely interference on your own part would effectually remove. Write again,

MEETINGS OF THE SOCIETIES.

WEDNESDAY, APRIL 4TH.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Mr. G. B. Longstaff, On Phthisis, Bronchitis, Pneumonia: are they Epidemic Diseases?

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown.—Dr. Fancourt Barnes, On a Case of Labour with Atresia Vaginis.—Dr. Herman, On Gangrene of the Vulva.

Vacancies.

Chichester Infirmary.—House Surgeon and Secretary. Salary, £100, with board and lodging. Applications to be addressed to the Secretary on or before April 7th.

Lincoln County Hospital.—House Surgeon. Salary, £100, with board and lodging. Applications to be sent to the Secretary on or before April 23rd.

Oxford Medical Dispensary and Lying-in Charity.—Surgeon and Apothecary. Applications to be sent to the Secretary on or before April 9th.

Appointments.

BROWN, W., L.R.C.P. Ed., M.R.C.S., Medical Officer of Health for the Carlisle Urban Sanitary District.

HAMILL, E. J., M.D., Q.U.I., L.R.C.P. Ed., Medical Officer for the E and F Districts of St. George's Union, London.

HORSFALL, H., M.B., M.R.C.S., Medical Officer of Health to the Bedale Rural Sanitary Board.

MACBRYAN, H. C., L.R.C.P. Ed., Assistant Medical Officer to the Middlesex County Asylum, Hanwell.

ROGERS, E. C., M.R.C.S., Medical Superintendent of the Cambridge-shire Asylum at Fulbourn.

SANDERS, C., M.B. Lond., M.R.C.S. (late House Surgeon), House Physician to the Queen's Hospital, Birmingham.

SANDERS, R. C., L.R.C.S.I., Medical Officer for the Marton District of the Rugby Union.

STEVENS, L. W., M.R.C.S., L.R.C.P. Ed., District Surgeon of Rebertson.

Births.

INKSTER.—March 30th, at Fulwood Road, Sheffield, the wife of Dr. S. Macaulay Inkster, of a daughter.

POWELL.—March 29th, at Elm Cottage, Beckenham, the wife of H. A. Powell, M.A. Oxon, M.R.C.S., &c., of a daughter.

WEIR.—March 31st, at Connaught House, Norwood, S.E., the wife of Walter Weir, M.D., of a son.

Marriages.

BOTT—WOLSTENHOLME.—March 29th, at St. Andrew's Church, London, W., Wm. Gibson Bott, L.R.C.P., M.R.C.S., of 61 Kennington Park Road, to Camilla Anne Kirkman, widow of Thomas Wolstenholme, of Kennington.

Deaths.

CHALDECOTT.—March 26th, at Harcourts, Chertsey, Surrey, Thos. A. Chaldecott, M.D., M.R.C.S., late of Hongkong.

CLENDINNEN.—March 21, at Dublin, Dr. Clendinnen, late of Minvrad House, Carlow, aged 79.

ETON.—March 26th, at his residence, Stoke Poges, Edward William Eton, M.B., late of Windsor, aged 72.

GRUGEN.—March 22nd, at his residence, Pilgrim Street, London, Wm. John Grugen, M.D., late E.N., aged 64.

IRWIN.—March 26th, at his residence, Belvoir Street, Leicester, Wm. Crossley Irwin, M.D., aged 74.

MOLLINCK.—March 26th, at the Grove House, Church Stretton, Salop, J. R. Mollinck, M.D.

MONTEFIORE.—March 26th, at Portman Square, London, Nathaniel Montefiore, J.P., F.R.C.S., aged 63.

MORRIS.—March 19th, at Burns Street, Nottingham, B. R. Morris, M.D., of Burnham, Somerset, aged 66.

OWEN.—March 28th, at his residence, Tue Brook Villa, Liverpool, Harold Owen, L.R.C.P. & M.R.C.S., aged 60.

QUARTLEY.—March 28th, at 54 Lancaster Road, Finsbury Park, London, Francis Cecil Quartley, M.R.C.S. Eng., aged 85.

ROBATHAN.—March 27th, at the Grove, Eisco, Mon., Edward Robathan, L.R.C.P. Ed., M.R.C.S., aged 73.

RUSSELL.—March 30, at 89 The Terrace, Gravesend, George Ireland Russell, M.D., F.R.C.S., aged 55.

ON ABDOMINAL PULSATION.

By ALFRED WILTSHIRE, M.D., F.R.C.P. Lond.,

Joint-Lecturer on Obstetric Medicine, and Physician-Accoucheur for Out-patients at St. Mary's Hospital; Physician for the Diseases of Women to the West London Hospital; Treasurer of the Medical Society of London; late Member of the Council of the Clinical Society of London; Corresponding Fellow of the Obstetrical Society of Edinburgh; formerly Medical Inspector to Her Majesty's Privy Council, &c.

ABDOMINAL pulsation is a symptom not unfrequently complained of by adult, middle-aged, or elderly women, particularly about the climacteric, or shortly after (who say they have a "beating in the inside"), and comparatively rarely by men.

The symptom may become distressing, because of its unremitting persistence, or because it alarms, worries, and prevents sleep, but seldom, in simple cases, on account of pain. Some of these patients are supposed to have aneurisms, mostly of the abdominal aorta, but, while allowing the possibility of this, it is, in my experience, a rare occurrence in women. I have known the diagnosis of aneurism arrived at where none existed; and I propose showing a specimen recently taken from the body of a woman in whom this diagnosis was made and maintained for several years by more than one physician, when at the post-mortem examination no trace of an aneurism, or even of dilatation, fusiform or other, was found.

In this case, as in others, I was unable to concur in the diagnosis of aneurism; and the post-mortem examination, for which we had to wait several years, satisfactorily confirmed this view, the artery presenting no signs of disease.

The patient was a married woman, aged 50 years, and during several years she had from time to time been under the observation of two physicians and myself. She presented a marked example of distressing pulsation in the abdominal aorta, and although the beating and jarring sensations were troublesome, I could never satisfy myself

of the existence of aneurismal, or even fusiform, dilatation of the vessel. Accordingly, I could not subscribe to the view that an aneurism existed; I looked upon the case rather as neurotic, and aggravated by constipation; and, as the specimen which, by the kindness of my friend and colleague, Dr. Goddard Rogers, I am enabled to show, will demonstrate, there is no sign of any lesion of the aorta. She died with cerebral symptoms: fatuous dementia, but no coarse signs of cerebral lesion were found post mortem by our senior house-surgeon, Mr. Schacht.

One of the chief objects I have in bringing forward this communication on abdominal pulsation is to elicit the views of others perhaps better informed upon the subject, which is one still involved in considerable obscurity as regards the etiology of certain forms of it.

The symptom, though by no means always of grave significance, is yet met with sufficiently often to require that attention should be paid to its causation; its etiology, as regards certain cases, still remaining obscure. Laycock ("Nervous Diseases of Women," p. 272) remarks that the subject has been discussed from Morgagni downwards without educing much exact information as to its pathology. He says that according to Elliotson epigastric and abdominal pulsations were attributed by Sauvages to morbid sensibility of the arterial system, particularly of the gastric arteries and aorta; while Pomme referred them to the celiac and superior mesenteric arteries and aorta.

Symptoms.—As a rule the chief complaint is of an incessant beating in the abdomen, which becomes troublesome because of its persistence. Some patients complain that the beating shakes them so that they cannot sleep; others become alarmed and restless at the unwonted commotion in their bellies.

When asked to indicate the seat of their trouble they usually point to a spot in the centre of the abdomen a little above the umbilicus, sometimes higher, rarely lower. The beating may be felt anywhere between the epigastrium and the lower end of the aorta. As a rule the physician can feel—he can even sometimes in thin patients see—a quick-throbbing, sharp pulsation, which, on being defined, is commonly found to be in the abdominal

aorta. If the tips of the examiner-fingers be gently but firmly thrust backwards, the calibre of the aorta can generally be easily made out. When this is done its physical condition should be accurately observed. Is it unduly hard, large, broad, bulging, displaced, or obscured? It is usually desirable, for exact definition, to use the fingers of both hands simultaneously, so that the index and middle fingers of the observer's right hand may be placed on the left of the patient's aorta, while those of the left hand lie parallel on the patient's right. The aortic or other impulse can then be accurately observed and measured, and if it present an expansile character, so suggestive of aneurism, it cannot fail to be detected. One finger lightly placed over the pulsating vessel will show the rate and character of the impulse, which is often quick, sudden, and kicking, like a hammer-pulse. In certain cases there is a vibratile thrill, which may own at least three if no more causes, as will presently be explained.

In many cases the abdominal walls are very thin, permitting easy recognition of the pulsation. There may also be wasting of the omental, peri-renal, and mesenteric fat, as well as of that of the parietes, and in these cases the abdominal contents, aorta, and spine can be felt with preternatural distinctness.

Complaint of severe pain, whether abdominal, dorsal, or more distant, should lead to careful examination, for it may signify aneurism, embolism, or malignant disease. It is seldom prominent in simple cases. Auscultation in the back as well as in front should never be omitted in such cases, for aneurismal bruits may sometimes be heard only posteriorly. Besides, spinal deformities may be detected, and care should be taken not to overlook exostoses or other growths deflecting the vessel.

Should any large masses or fluid collections be met with, they should be carefully explored and scrutinized, and their nature and relations accurately ascertained, especially with reference to the aorta. The presence of tumours elsewhere should also be noted, e.g., of lymphadenomata, lympho-sarcomata, &c. Spinal lesions from aneurismal pressure should never be forgotten.

Accompanying the local signs, symptoms of general import may present themselves. For example, some patients have prominent, perhaps tortuous, red capillaries upon the cheeks, the vessels remaining permanently more or less distended. They are said to always "have a colour," whatever the state of their health. The more aged may display other symptoms of vascular degeneration, as rigidity and tortuousness of the arteries, visible at the bend of the elbows and elsewhere. In others an unnatural pallor of the face is seen, with an opaque hue of skin. These conditions are suggestive of general vascular degenerative change (atheroma), accompanied or not by cardiac defect. The hair is seldom silky, and the palms are harsh. In young patients no notable alteration in the aspect or dermal state may be present, unless in Addison's disease, which is often accompanied by undue abdominal pulsation, or in anæmic or chlorotic cases. I have rarely seen jaundice associated with abdominal pulsation, unless with organic hepatic disease. Some are the subjects of chronic renal disease, and others are martyrs to dyspepsia.

Causes.—These are numerous, and, as a brief review will show, often require careful discrimination, some of them involving serious consequences. But the majority of cases are not dangerous, if troublesome: the significance of the symptom varies so considerably, however, that caution is required before a positive opinion is enunciated. The survey should be wide enough to embrace all the possible causes, foremost among which stands affections of the vascular system. Disorders of the vascular system first demand attention, alike from their frequency and importance. The aorta (or its branches) may be implicated either by structural or functional disease at its origin or in its course, or by obstruction of its calibre between its proximal and distal ends; the blood it carries may be disordered; the cardio-aortic valves may be

incompetent, and permit regurgitation; or the peripheric arterioles may be at fault.

Aneurisms may occur in the aorta or its branches, and, besides a pulsating tumour, may cause severe pain from pressure. Fusiform dilatation is also believed to be present in certain cases.

The aortic walls may have undergone so much degeneration that the vessel feels like a rigid tube, rolling under the finger like a large pipe of macaroni. Under such circumstances it is obvious that the blood circulates with less ease, the friction being greater, while the help towards forward propulsion of the stream derived from the elastic recoil of healthy arteries is wanting. Again, sudden jars or succussions, such as may be produced in leaden water-pipes when a rapidly-flowing current is abruptly arrested by a smart turn of a tap, excite vibration in rigid tubes; more readily than in extensible ones; and thus, probably, some examples of abdominal pulsation may be produced or favoured, when, for instance, incompetent semilunar valves permit of a sudden reflux, which the inelastic vessels are not competent to compensate by closing down promptly upon the diminished current. Other factors, then, have to be considered here—the quality of the circulating fluid, as well as the mechanism of the pump or driving apparatus.

It is clear that oil, glycerine, or fluids of similar consistence, vibrate much less readily in solid tubes than thinner fluids, such as water. Therefore the amount of vibration in some instances of abdominal pulsation may depend to a certain extent upon the quality of the blood, which, if hydræmic, thin, poor, and wanting in albumen and fibrin, will produce greater commotion than rich, viscid blood. The hæmic murmurs and rushing noises felt in the head by anæmic and chlorotic girls prove this: they vanish with improved hæmatosis.

Anæmic, chlorotic, hysterical and hypochondriacal young women, and occasionally men, may experience epigastric pulsation, but they mostly get well with a purge and improvement of their blood.

Then, incompetence of the aortic valves permits regurgitation of blood backwards into the heart; the arterial system gets an impulse, often of exaggerated character, from ventricular hypertrophy, which fails so quickly as to produce a sense of back-thrust from the collapsing of the unsustained current, the vessels being inadequately filled. This condition may unaided excite the worst form of abdominal pulsation, but it is intensified by atheroma and poor blood. A kind of hammer-pulse is produced, and in thin people, whose abdomens are shallow, the violent beating causes distress.

A combination of aortic valvular incompetence, with the secondary cardiac mischief sooner or later ensuing (hypertrophy and dilatation), rigidity of the walls of the vessels, and impoverishment of blood, may produce the gravest form of morbid abdominal pulsation. Inquiry should therefore be made into the integrity of these parts. True aneurisms are rare in women; and even the "fusiform dilatation" so often assumed to exist is rarely found *post mortem*. Degenerative changes, however, may be observed.

Pressure upon the lower portions of the aorta may provoke a sense of undue pulsation in the upper reaches of the vessel; and I believe I have seen this arise from fecal accumulations pressing upon the left iliac artery near its origin. It is unnecessary to remark that tumours of any kind encroaching upon the aorta may impede the blood-current and throw back a wave, e.g., pancreatic growths, or cysts of the mesentery, as in one of my cases.

There is another, and probably the most common form of vascular disorder, that which appears to be functional, and has been called "idiopathic," but which is probably a vaso-motor neurosis, possibly dependent upon implication of the sympathetic. This is the common form, seen in middle-aged women, wherein no structural lesion of vessels can ever be discovered either *ante* or *post mortem*. It may occur after severe mental trouble or shocks; or

in association with the vascular turgescence or erethism of the change of life; or after severe hæmorrhages, as after delivery or abortion, or without apparent cause.

Another variety of the affection appears to be due to renal degeneration, where spasm of the systemic arterioles provokes general high tension; but this is less clear.

Tumours lying over the aorta, notably if soft, may have an impulse conveyed to them by the subjacent vessel, and produce abdominal pulsation. This may happen in soft cancers (encephaloid or colloid), or in other forms of morbid growth, as sarcomata, hydatids, &c.; or by horse-shoe or movable kidneys. Dr. W. Roberts ("Reynolds' System of Medicine," vol. v., p. 643) says:—"Epigastric pulsation is a frequent concomitant of mobility of the kidneys." An abscess overlying the aorta may provoke painful pulsation. The cardiac impulse may in rare cases be conveyed downwards, as in pleuritic effusions and intra-thoracic tumours, mediastinal and other, with downward displacement of the organ; or in pulsating tumours of the liver, encephaloid and other.

Tumours of no great size, and not directly connected with the aorta (e.g., movable kidneys), but in the recumbent position lying immediately over it, may so press upon the vessel as to hinder the onward flow of blood, and thus be lifted up at each systole of the heart, which may accordingly be called upon to labour more forcibly to propel the blood past the obstacle. When this accident is suspected, and indeed in most cases, the patient should be examined in the lateral position. It has occurred to me to observe the pulsation disappear on the dorsal being changed for the lateral decubitus. The possibility of aneurism complicating an abdominal tumour should never be lost sight of, and spinal caries from pressure and erosion has high significance.

In exaggerated gaseous distension of the abdomen every throb of the aorta may excite distress and provoke a kind of reverberation. This seldom occurs in free fluid effusions, such as ascites; but may when a localised abscess encroaches upon a vessel.

Abdominal pulsation may oppress puerperal patients after severe hæmorrhage, when it is best treated by opium. It may also supervene on hæmorrhage from abortions and from other causes. I have at present (Dec. 4, 1882) a patient in the West London Hospital who has suffered from abdominal pulsation ever since a severe flooding after a miscarriage three years ago, (a) but greatly aggravated by another miscarriage a month ago.

Abdominal pulsation commonly accompanies Addison's disease. The association suggests possible implication of the sympathetic system, and alliance with other neurosial forms of the disorder. In an article on "Addison's Disease," &c., in the *Amer. Jour. of Med. Science*, April, 1877, p. 335, Dr. Pepper says that pulsation of the aorta is present in a large proportion of cases, and that its detection is rendered easy by the retraction of the abdominal walls which often exists. He quotes Gerhardt to the effect that in some cases there has been apparent dilatation of the vessel. It is doubtful whether the blood is thicker than normal, as some suppose.

With reference to the retraction of the abdominal walls so often met with in aortic pulsation, it has seemed to me that the closer apposition of the sensitive anterior wall may render more apparent to the patient than usual the normal beating of the aorta; and this might be favoured by the absorption of adipose tissue so constantly seen.

It may be likened to the keener perception of foetal movements by pregnant women after the gravid uterus has risen out of the pelvis and come into contact with the belly wall, as happens on quickening. The buffer-like effect of a good cushion of fat in the omentum or abdo-

minal parietes is considerable; and patients who regain flesh are less conscious of the beating.

Treatment.—This must obviously depend upon the cause, but clinical experience justifies the broad statement that in the majority of ordinary cases a vascular sedative, such as potassium iodide, is most efficacious. This applies equally to neurosial as well as aneurismal cases. But no case should be treated empirically.

When heart disease exists it must be treated; and so with blood impairment. In the presence of anæmia with hydræmia or spanæmia improvement of the blood by hæmatinic, such as iron, is essential. But in most of the hydræmic cases a highly albuminous diet is also important, there being often a marked deficiency in that element in the serum. A generous dietary is profitable, and one rich in meat, eggs, and fish is requisite. To aid the frequently-impaired digestive powers, peptic agents should be employed—pepsine, pancreatine, lacto-peptine, Benger's preparations, Savory and Moore's, Morson's, Bullock's, &c. Dyspeptic symptoms should never be neglected, for a distended stomach may intensify the trouble. Bismuth, charcoal, and soda are therefore useful. Aperients are of considerable importance, but they should be *laxatives* rather than purges, e.g., decoction of aloes, or rhubarb, or magnesia, rather than salts. An excellent combination for many cases is R. Potassii iodidi, gr. v. or x. in dec. aloes co. ℥j. bis die. Belladonna often forms a valuable addition to internal treatment; while a full-sized belladonna plaster over the seat of beating helps to soothe and calm the patient. Digitalis proves useful in certain cases.

In vascular disturbance due to renal inadequacy the kidneys demand attention, and the adjuncts of aperients and sudorifics should not be forgotten. Agents that influence arterial tension may here prove serviceable, such as amyl-nitrite, nitro-glycerine, bromides, &c.

Some of the climacteric cases resemble those due to renal failure, and partly for the same reason, the elimination of nitrogenised waste products becoming defective; and here depurating treatment, combined with the bromides, is serviceable. The salts of iodine and bromine appear to yield better results than other drugs in this malady, whatever its origin, but particularly the iodide of potassium.

Now and again ergot of rye answers better than other medicines. It seems to influence cases which present symptoms of relaxation of the systemic arterioles, where the blood-current appears to slip round too quickly, and the arteries beat loosely, the pulse being soft and compressible. This may be witnessed in examples of transient abdominal pulsation. Firm doses of ergot occasionally prove beneficial in other forms of abdominal pulsation attributable to vascular disorder; and the same may be said of opium in substantial doses, especially after severe losses of blood. Camphor, either alone or in combination with iodides and bromides, may afford much comfort in patients oppressed with indefinable apprehensions; and so may pulsatilla.

But the chief agent in relieving abdominal pulsation is iodide of potassium. Its great value in arterial disorders, particularly aneurism, has been ably shown by Dr. Balfour; and my experience of its action in most cases of uncomplicated abdominal pulsation warrants the holding of a high opinion of its merits. The dose should not be less than five grains to begin with, and double this, or more, may occasionally be requisite. It is well to combine with it a little carbonate of ammonia, or potash if the urine be lithatic. It goes well with decoction of aloes when the latter is indicated. Should coryza be complained of, small doses of tincture of opium may be added when not otherwise contra-indicated.

Of the bromides, those of sodium, lithium, and ammonium are somewhat less depressing than that of potassium, but it is not often that large doses are called for.

Digitalis may be useful in cases of cardiac incompetence, and when symptoms of renal disorder are present.

When abdominal pulsation suddenly supervenes upon

(a) This patient, who is a fair (xanthochroic) woman, presents an uncommon exception to most of her sex who have borne children, or had the abdominal parietes otherwise distended, in that she has an almost complete absence of *linea albicantia* on her abdomen or thighs, although she has borne several children. The only marks detectable are two insignificant streaks at the junction of the right thigh and groin. I have another example of complete absence of white lines in a multipara.

menstrual suppression in climacteric women, and is accompanied by evident venous engorgement, no remedy equals bleeding, a venesection to \bar{v} viij. or \bar{v} x. promptly assuaging the commotion and relieving the oppression.

Aconite, however, is in some cases an efficient substitute.

ON CATARRHAL ULCERS. (a)

By RUDOLF VIRCHOW, M.D.,

Professor of Pathological Anatomy in the University of Berlin.

THE speaker at the commencement expressed himself as opposed to the view so widely spread, more especially by Niemeyer's Handbook, and addressed himself primarily to answering the question, What, properly speaking, is a catarrh? He himself had adopted the old view, according to which catarrh is derived from *Karapptu*—i.e., that catarrh is the separation of something that is movable, and that can be removed from the place of separation; it is also to be understood that the separation takes place from an unwounded surface. The old notion of a catarrh was originally associated with the nose, and only at a later period and quite gradually became applied to the other mucous membranes. He, the speaker, left quite untouched the question how far the glandular structures lying outside the proper mucous membrane contributed to the secretion, and confined himself strictly to those surfaces from which the secretion took place. Although he confined himself to this narrow view of catarrh, he laid the greatest stress upon the secretion itself.

Catarrh cannot be diagnosed from the condition of the mucous membrane itself, but only from the fact of its secreting, whence we are not justified in designating another condition of the mucous membrane, though it may be similar, as catarrh when no secretion follows—for instance, that which has been designated "dry catarrh." This dry catarrh has been variously designated at the various periods of its existence. Some have conceived of it as gradually losing the fluid character of its secretion, which has become changed into a firm compact adherent mass. The speaker had no comprehension of such a dry catarrh, in which nothing more was secreted. Others, again, who have not recognised this limit, have gone further and further, so that the conception of catarrh has become more and more extended, until, for some organs, no further conditions remain. Some medical men have therefore reached the conclusion that the stomach suffers from no other further affections than catarrhs. The speaker felt himself bound to protest against these views, not only as a pathological anatomist, but also as a logical physician. That the stomach is capable of secreting large quantities of mucus, autopsies show, in which the stomach is not unfrequently found covered with a layer of mucus of the thickness of a finger; but one had no grounds for widening the conception of catarrh, so as to include all inflammatory irritable conditions of the stomach, which set up no secretion whatever.

Does a catarrh produce ulcers?—i.e., are ulcers to be considered the regular production of a catarrh? It is clear that any pathological condition may give rise to other dispositions, which in turn may lead to further consequences which the original simple disease would not have produced. If, for example, a delicate child had a violent nasal catarrh, it very commonly happened that conditions arose in which the epidermis was easily separated, erosions, and after drying up a scab formed; under this, suppuration took place, and finally an ulcer was formed on the spot. Grouping this series of sequences, one might easily say that the child had a catarrhal ulcer on its upper lip, or on a spot where there was no catarrh. Finally, we got a cutaneous ulcer, but

we had no grounds whatever for calling this kind of ulcer catarrhal. The older physicians, indeed, have clung most perseveringly to the idea that under such circumstances erosive ulcers could arise, and this idea had become so wide-reaching that the most important conditions have been grouped under it. Thus, some decenniums ago the great teachers of medicine in France clung to the idea that the laryngeal and tracheal ulcers of phthisis had their origin in erosions caused by the irritating effect of sputa upon the mucous membrane. Since then, the speaker had more and more convinced himself that this kind of action exercised by secretions upon neighbouring parts, previously intact, in regions covered by mucous membrane (not) provided with pavement epithelium, was not to be met with, but that the existence of these forms might be assumed everywhere where pavement epithelium existed; whether the secretion were catarrhal, or whether it came from ulcerated cavities, seemed to him to be a matter of indifference. Such surfaces provided with pavement epithelium were tolerably extensive. Such a tract could be followed from the lips to a little below the cardiac orifice of the stomach. In the respiration tract such surfaces were of very limited extent, as, for instance, in the posterior wall of the larynx, between the arytenoid cartilages. Upon these surfaces occasionally appeared a peculiar kind of ulcer, which should be called erosive, inasmuch as certain spots were deprived of their covering, and soft moist surfaces were exposed. These, of course, did not dry so rapidly as those on the external skin, but, being deprived of their epithelium, they were constantly being subjected to fresh irritation; they readily became deeper, and, in fact, formed a kind of ulcer, developed upon these eroded patches. Similar conditions were met with at the conjunction of the cervical canal with the vagina at the os uteri. The secretions from the uterus gradually softened the pavement epithelium, which separated in large flakes; the blood-vessels on the exposed surfaces enlarged, and became engorged, and there arose during life dark or black red granular erosions, but no loss of substance, and ulcers scarcely ever, which, however, when they were met with, owed their development to the existence for years of the above irritations, which had gradually penetrated deeper and deeper. With regard to the other mucous membranes, neither in the whole of the mucous membranes of the respiratory tract, nor in the whole extent from the cardiac to the anus, nor in the uterus proper did simple erosions scarcely ever occur.

There was still another kind of erosion, which made its appearance on mucous membranes provided with cylindrical epithelium, and when the secretion was rapid and profuse, originated in a way similar to that in which vesicles were formed on the external skin. But, whilst on surfaces covered with pavement epithelium the connection of the parts was so intimate that they offered some resistance, the fluid forming a cavity under the surface, until when at last the covering burst, erosion had taken place, on surfaces covered by cylindrical epithelium the formation of vesicles was generally not possible, as the covering was so delicate, but the mucous membrane rather became separated at once. This was the case with all diseases associated with violent diarrhoea, and indeed this observation was first made in cholera, and then in ordinary typhus, as in typhus in epidemics, in which much diarrhoea was present. The examination of these erosions had not yet resulted in much, for the reason principally that the pathological anatomist had made his investigations at much too late a stage—when many secondary changes had already set in. It would be the task, therefore, of the clinician to study the subject more accurately, by the aid of the microscope, in the dejecta of the living.

It was easy to conceive that on those mucous membranes that were thus deprived of their epithelium by copious exudations, surfaces thus deprived were exposed in a high degree to injurious influences. On these un-

(a) An Address delivered before the Berlin Medical Society, Jan. 11, 1883.

protected places it was easy for new colonists of all kinds to settle down, such as bacteria, &c. It should be mentioned that some medicines—such, for instances, as large doses of mercurial preparations—might give rise to these erosions. This settlement was called diphtheria, and had the appearance of a primary diphtheritic process, but the stages of development were first erosion, then diphtheritic infection by parasites, and lastly diphtheritic ulcer. A remarkable example of these processes was the ulceration—first called uræmic in Prague—in which the separate stages could be plainly observed. Here also there was no specific uræmic ulcer, dependent on uræmia, but a diphtheritic ulcer for the development of which the uræmic condition afforded the most favourable soil. If every diarrhoea was called an intestinal catarrh, so also the uræmic condition might be also called catarrhal.

Again, a catarrhal angina was spoken of, but the angina was not catarrhal; the affection was rather *angina cum catarrho*, or *catarrhus cum angina*. Since we had learned that the tonsils, the pharyngeal and tongue follicles are really lymphatic appliances, it had become much more comprehensible that the affections of these parts had similar relation to the swellings of the glands external to the mucous membranes. One would not say of a patient suffering from nasal catarrh, whose jugular or cervical lymphatic glands were swollen, that he had catarrhal swelling of the lymph glands, and yet this was what was said of the flamed tonsils. If an abscess formed in a tonsil, opened and lead to the formation of an ulcer, the conclusion to most would seem to be perfectly justifiable: first, angina and catarrh, then ulcer—*ergo*, catarrhal ulcer. This kind of reasoning could, of course, be applied to all the lymph apparatus, and thus this kind of ulcer had extended itself everywhere. Just as in the tonsils, so all through the digestive tract abscesses might form in the follicles; these might mature and break, and leave ulcers, and even a great part of the so-called tuberculous ulcers, the speaker looked upon as follicular. These lymphatic abscesses had exactly the same significance as an ulcerated bubo.

In conclusion, he mentioned the deeper and more remote processes which are occasionally set in motion in the course of a catarrh, periostitis, perichondritis of the nose, or of the tracheal cartilages, which, by the same course of reasoning, might be called catarrhal. If it be found that the same perichondritis was presented to us in syphilis, typhus, diphtheria, and tuberculosis of the larynx, that, first of all, distinct syphilitic, typhus, or diphtheritic disease of the surface arose, and that only now and then, in the deeper-seated parts, perichondritis and afterwards abscess appeared, burst, and increased the size of the, probably, already existing ulcer, it seemed to be safer for the judgment, if we did not attribute this perichondritis to the one or the other process, but to consider it by itself, and decided in each individual case whether it had any connection with any particular or special process. As soon, then, as the various phenomena were examined more nearly, and we took pains to arrange them in a distinct order, the catarrhal ulcer vanished of itself, since it had nothing special whereby in diagnosis we could distinguish it from others. He was convinced that our knowledge of detail would gain much if, instead of making use of ætiological designations, we employed such as resulted from those processes in consequence of which the ulcer arose.

DR. JAMES MANBY GULLY, formerly of Great Malvern, died in London on the 27th ult., at the age of 75. It will be remembered that Dr. Gully's name was before the public in connection with the Bravo case. Deceased's practice, which was large, was principally directed on hydropathic lines.

THE CAUSES, SYMPTOMS, AND TREATMENT OF PHIMOSIS AND PARAPHIMOSIS. (a)

By LAMBERT H. ORMSBY, F.R.C.S.,
Surgeon to the Meath Hospital and Co. Dublin Infirmary; Lecturer on Clinical and Operative Surgery.

(Continued from page 293.)

4. *Single Incision of the Prepuce on Director.*—This treatment, next to complete circumcision, is the most satisfactory mode of treating phimosis. It is a more serious procedure, however, than the other plans mentioned, and could hardly be performed unless under the influence of an anæsthetic. A patient would not, as a rule, submit to the pain without being rendered unconscious. The instruments, &c., required would be—1. A sharp-pointed knife or bistoury; 2. A grooved director; 3. A sharp pair of scissors; 4. A needle armed with silk catgut or silver wire; lint, bandages, sponges, &c., a mackintosh sheet. The slitting plan is performed as follows:—The prepuce is grasped in one hand, and gently pulled forward; a grooved director is then passed backwards until it becomes prominent under the skin above and at the side of the glans, proving that the point of the director has not entered the urethra. The director thus *in situ*, is given to an assistant to hold, and a sharp-pointed curved bistoury is then passed along the groove, and made to transfix the skin, and then carried forwards until the prepuce is entirely slit up (Fig. 1). If it is adherent, the adhesions must be gently broken down with the finger or the handle of a scalpel or small spatula. The two corners of the incised prepuce can then be trimmed round, and removed from above downwards and forwards, so as to make the parts as neat as possible, and to prevent any redundant tissue remaining when cicatrization takes place. The slit in the prepuce had better be made on the upper side, and when the corners are removed by a sharp scissors very little, if any, disfiguration remains behind, provided that the skin and mucous membrane are evenly and closely brought together with silken, catgut or wire sutures. In this incision a vessel or two may be cut, but the bleeding can be controlled by passing a suture through the bleeding point. It is then dressed with strips of wet lint. The parts generally heal in about ten days or a fortnight. The sutures ought to be removed about the end of the first week.

The Ancient Rite of Circumcision.

5. The operation of circumcision as far as we find it recorded, is a very ancient custom. In Bible history we find that the Patriarch Abraham, at the age of 99, circumcised himself and all the males of his family (see Genesis, Chapter vii., verse 10). Other writers believe the custom was even practised before the year of the world 2,178.

The rite of circumcision by Abraham was considered a seal of a covenant between the Creator and the created. Circumcision, pure and simple, is a Latin word denoting the cutting off or cutting round of the prepuce or foreskin; the act of doing so being a recognised ceremony in the Jewish and Mahomedan Churches, and it is ordained that all males shall have their foreskins cut off who profess one or the other religions.

The ceremony, then, is by no means confined to the Jews, for from the perusal of the writings of Herodotus, it was a very ancient custom, much practised by the Egyptians, Ethiopians, and other oriental nations; and, for this reason, it is difficult to ascertain which nation practised it first. The same historian relates that the inhabitants of Colchis also practised circumcision, whence he concludes that they were originally Egyptians. He adds, furthermore, the Phœnicians and Syrians were likewise circumcised, but that they borrowed the custom from the Egyptians. The writer Marsham is also of the opinion that the Hebrews acquired their knowledge of circumcision from the Egyptians, and that Abraham

(a) Being a clinical lecture delivered in the Meath Hospital and Co. Dublin Infirmary.

was not the first to practice it, and cites the ancient historians Diodorus, Siculus, and Herodotus to support his views on this subject.

Be this as it may, it is quite clear the rite of circumcision among the Jews differed widely from that of the Egyptians and other nations. Among the former it was distinctly a ceremony of religion, and was performed on the eighth day after birth of the child. Among the Egyptians and other races it was performed more as regards decency, or on the score of cleanliness and sanitary hygiene than anything else, or as some will have it, of physical necessity, and was not performed till the

In tracing the custom in Bible history, we find that the Jews, at least as a race, have always been from the earliest records most exact in observing this ceremony. It was made known to Moses, and ordained that all who intended to partake of the Paschal Sacrifice should receive circumcision as early as the eighth day of birth. Even during their captivity in Egypt, the rite was not altogether neglected.

Moses, however, while in the land of Midian with Jethro, his father-in-law, did not circumcise his two sons born in that country; and during the journey of the Israelites in the wilderness, their children were not

FIG. 1.

thirteenth year, and then as often on girls as boys. Circumcision in women denotes the cutting off the foreskin of the clitoris, which bears a close resemblance and analogy to the prepuce of the male penis. The Arabians, Saracens, and Ishmaelites, who, as well as the Hebrews, sprang from the seed of Abraham, practised circumcision, but not as an essential rite which they were bound to perform, on pain of being cut off from the people. The operation of circumcision, if properly performed in the first instance, cannot be repeated, although the Jews recommended, when admitting a Proselyte, they should perform the rite nominally by drawing a few drops of blood from the part. (A Proselyte denoting a name given by the Jews to those who came to dwell in their country, or who embraced their religion, not being Jews by birth.) Therefore, when the Jews admitted a Proselyte of this kind, although he may have been previously circumcised, they must perform the custom by going through part of the ceremony and drawing a few drops of blood, which is called the "Blood of the Covenant."

The Jewish race consider the foreskin or prepuce as a very great impurity, and the greatest offence they could receive was to be called uncircumcised. Paul (Romans Chapter ii., verse 26) frequently designates the Gentiles under this term in opposition to the Jews whom he calls circumcision. Paul also alludes to the imperfect manner of circumcision, or partial removal of the foreskin, which apparently was practised by the Edomites, Egyptians, and other races; this he calls *concision*, and associates those who practised it with dogs (Phil., Chap. iii., verse 22).

The Jews distinguished their Proselytes into two sets according as they became circumcised, or not; those who submitted to this rite were looked upon as children and followers of Abraham, and obliged to keep and obey the law of Moses. The uncircumcised Proselytes were only bound to observe the precepts of Noah, and were thus called Noahchidæ.

The custom among the Turks is never practised till the seventh or eighth year, and the race do not at all believe the performance of the rite is necessary to their salvation, and in no way recognise it as a religious ceremony. The early Persians circumcised their boys at 13, and their girls from 9 to 15. Those of Madagascar cut the flesh at three different times, and the most zealous of the relations present caught hold of the prepuce when removed and swallowed it.

circumcised, probably by reason of the danger which might accrue after the operations by being exposed to the vicissitudes of travelling, sudden removals, unsettled state and manner of living in a dry and sandy desert.

So far as we can ascertain, the law does not clearly lay down whose duty or function it was to perform the operation, or with what instrument it was to be accomplished. A sharp stone, sharp knives, and in modern times, a sharp razor are among the instruments mentioned as being used (see Exodus, Chapter iv., verse 25; Joshua, Chapter v., verse 3). The ancient mode of performing the operation, according to the Jewish rite, was carried out after the following manner:—There was a godfather to hold the child, and a godmother to carry it from the house to the synagogue or place where the operation was performed. He who circumcised was called in Hebrew *Mohel*. Any person was chosen for the purpose, indifferently, provided he were capable of the function which, among the Jews, was a title of very great merit. The manner of the ancient ceremony is graphically related by Leo de Modena, and is as follows:—The operation is always performed on the eighth day after birth. Two seats are prepared in the morning with silken cushions, one for the godfather, who holds the child, the other, as they say, for the Prophet Elias, whom they suppose to assist invisibly. The person who is to circumcise brings the necessary appliances—the razor, styptics, linen fillet, oil of roses, to which some add a shell full of sand to catch the blood, and put the prepuce in when removed. A Psalm is sung till the godmother brings the child, attended with a crowd of women, and delivers it to the godfather, none of them entering the door; the godfather, being seated, sets the child on his lap, then the Mohel, or circumciser, taking the razor and preparing the child for the operation says with a loud voice: Blessed be Thou O Lord who has enjoined us circumcision. And on so saying cuts off the thick skin of the prepuce and with his finger-nails tears off another finer skin remaining, sucking the blood, by putting the penis into his mouth for two or three seconds and then spitting out into a glass of wine. Then he lays dragon's blood on the wound with powder of coral and other styptics to arrest bleeding, and staunch any blood that might flow. Over all he places a fillet or compress saturated in oil of roses, and then binds up the whole; that being done, he takes a glass of wine, and blessing it, adds another benediction for

the child and imposes the name ; the child is then given by the godfather to the godmother, who carries it back to its mother.

The modern Jewish ceremony of circumcision differs slightly from the description just given. The mode of the performance as at present observed is as follows, and was related to me by a medical friend who was present at the operation :—It was performed on the occasion by the chief man among the Jews residing in the place. The ceremony took place on Sunday morning, the eighth day after birth. Many people were present, chiefly of the Jewish persuasion. The infant was held by the godfather or person of distinction, the operator grasped the prepuce, drew it forward, then applied a small piece of metal, with a slit in it, something after the manner of a clamp, and having drawn the prepuce tightly forward the clamp was held obliquely downwards and forwards, and then the prepuce in front of the clamp was removed with one smart stroke of a short-bladed knife. A glass of wine was placed on the table beside the operator, who, after division of the prepuce, took a mouthful of the liquid contained in the glass, and then bent down and took the child's penis in his mouth and, as it were, sucked the bleeding prepuce for three or four seconds, after which he spat out the blood and wine, and then bound up neatly the penis with strips of linen, and then gave over the child to its nurse. During the whole performance of the ceremony the operator repeated a form of prayer in the Hebrew tongue.

For further knowledge on this subject, much information will be derived from a perusal of a small work entitled "The Jewish Rite of Circumcision, with the Prayers and Laws Appertaining Thereto," translated into English with an Introductory Essay by Asher Asher, M.D., London.

In this work it mentions, "It is customary for the Mohel to read prayers publicly in the synagogue on the morning of the day on which he operates, or, at least, to read aloud the song of Moses (Exodus xv.) in the morning service. The custom arose from a literal interpretation of the verse (Psalm, cxlix, verse 6) 'Let the high praises of God be in their mouth, and a two-edged sword in their hand.'"

Dr. Asher says : "The child receives its name at the time it is initiated into the Covenant. It was an ancient custom, of which there are many illustrations in the Bible to give a new name to an individual on his accession to any great dignity or consecration to any particular service. The name of Abraham—a father of many nations—was conferred on our great ancestor on the occasion of the institution of circumcision (Genesis, Chapter xvii., verse 5). It is ordained that the operation be followed by a repast, in order to testify the joy of the parents on being permitted by Providence to initiate their child into the Abrahamic Covenant. The precepts for the performance of which—Israel have sacrificed their lives, they shall practise in happiness. And the verse of Scripture (Psalm i., verse 5) 'Gather my righteous ones together unto me, those who have made a covenant with me on the occasion of a sacrifice,' has been made to indicate the appropriateness of the festive gathering."

Dr. Asher also states, at page 26 : "The Talmud decrees that immediately after the amputation of the foreskin the operator shall, by means of his lips, apply suction to the wound, and cause the blood to flow ; and this is ordained as a remedial measure, the omission of which, like neglecting the dressing of the raw surface, is declared to be fraught with danger to the child ; and it is further ordained that the operator who is guilty of such omission shall be deprived of his office."

(To be continued.)

The infirmary of the Cambridge workhouse was destroyed by fire on Sunday last, fortunately without loss of life.

Clinical Records.

ST. BARTHOLOMEW'S HOSPITAL.

Ophthalmic Cases.

Under the care of Mr. BOWATER VERNON, F.R.C.S.
(Notes by Dr. W. J. COLLINS, B.S., B.Sc., Ophthalmic House Surgeon.)

CASE I.—*Embolism of Arteria Centralis Retinæ.*

G. W., æt. 49, a milkman, had rheumatic fever when 22 ; was laid up three months with it. Has enjoyed tolerably good health since, with the exception of occasional rheumatic pains in the shoulders and legs and attacks of dyspnoea brought on by exertion. For the last three months these have become worse, and he has been attending as an out-patient in the casualty department. On the morning of December 19th, 1882, after having seen the casualty physician he was returning home by train, when suddenly after a fit of coughing he saw as it were "like snow, only black," before his left eye, which became perfectly blind. He had no fit, nor any paralysis or loss of consciousness, and walked to his home all right. On the 30th December he applied at the hospital on account of the blindness of his left eye. He then presented the following appearance :—Face sallow, dilated venules on cheeks, alæ nasi dilating, and left eye totally blind—not even perception of light concentrated by a lens on cornea. With the ophthalmoscope, media quite clear, optic disc very pale and minus half its vessels, only veins visible, and they were natural in appearance, presenting no thrombi and no pulsation and no marked dilatation ; around the macula was a silvery dirty-white effusion, oval in form, with long axis horizontal about three times the size of optic disc, and shading off at its margin into healthy fundus ; its surface was traversed by delicate wavy lines like faint pencilings ; the whole of the silvery surface appeared to stand out somewhat in relief. The fovea centralis was of slightly darker shade than the natural fundus, with central oval orange spot. The right eye was normal, and the contrast of the fundus with that of the other eye was very marked—Vision = $\frac{1}{2}$. He had some dyspnoea, and cough, and bronchial expectoration. The heart's apex was just inside the nipple line ; cardiac dulness increased to the left and slightly to right ; a distinct aortic murmur audible at the apex and localised to its vicinity. The urine was acid, sp. gr. 1026 ; no albumen.

During the following week the changes around the yellow spot slowly disappeared, and by January 16th the whole of the effusion had cleared up, and the macula could be distinguished with difficulty. The disc had become as white as in advanced atrophy of the optic nerve, and the veins had been reduced in size. The eye remained absolutely blind.

CASE II.—*Anisometropia with Facial Asymmetry.*

E. C., æt. 12, complains that eyes are fatigued and painful after reading, especially in the evening. He is slow at his books, and gets blamed at school for stupidity. He has marked physiological asymmetry, the left side of the face, especially the frontal and zygomatic arches, being not only larger but better developed than the right. The left eye-brow is more arched than the right, and the left eye appears to be distinctly the larger of the two. On testing his vision it was found that the right eye was slightly hypermetropic, while the left exhibited compound myopic astigmatism, with great difference of refraction in the two meridians, thus :—

$$\left. \begin{array}{l} \text{R. E.} = \frac{1}{2} ; \text{ with } + 1 \text{ D} = \frac{1}{2} \\ \text{L. E.} = \text{nil} ; \text{ with } - .75 \text{ D spherical} \\ \qquad \qquad \qquad \text{and } - 3.5 \text{ D cylindrical} \\ \qquad \qquad \qquad \text{with axis horizontal} \end{array} \right\} = 1^{\circ}$$

CASE III.—*Ophthalmoplegia Interna.*

Edward C., æt. 28, a cabman, complains of "weak eyes," and recently developed "long sight," also of deafness of the left ear. There is no history or sign of syphilis, diphtheria, or injury. His distant vision with each eye = $\frac{1}{2}$, and with + .75 D = $\frac{3}{4}$; but he is unable to read the largest (No. 4) of Snellen's reading type at 12 inches without glasses. With + 4.50 D, however, he can read No. 1½ type at 12 inches. Ten minutes after eserine had been instilled into both eyes he could read No. 3 type at

the same distance, and tell the time with a watch at 4 inches. Both pupils dilated (size, No. 12) and immobile either to light or when looking at near objects. There is natural movement of the eyes in all directions, and no other symptom of paralysis whatever.

CASE IV.—*Blow on the Eye—Hyphæmia—Transient Nebulosity of Lens—Persistent Iridoplegia.*

Emily W., æt. 28, was walking along ——— Street when a beam of wood (3 ft. X 4 in.) fell from a window above and hit her left eye. She fell down insensible, and on recovering and coming to the hospital there was great pain in the eye, slight bruising of the lids, some pink injection of the sclerotic and hyphæmia to 1-10th of the anterior chamber. The turbidity of the aqueous rendered the naturally blue iris green; the pupil was irregular and eccentric, displaced downwards and outwards; media were hazy; there was no dislocation of the lens; the tension was normal, and the fundus returned a red reflex in all directions. There was no symptom indicating cerebral injury. The treatment consisted in atropine, and ice-cold applications; the hyphæmia decreased, the conjunctiva becoming "sallow," the anterior chamber was observed to be deeper than the right, and the eye continued to be tender. Four days later the fibres of the lens were seen preternaturally distinctly, oblique illumination exhibiting radial striae in the cortex; and with the ophthalmoscope a nuclear crescentic nebula was observed. A week after the injury the pupil was regular and central in position, and the lenticular nebulosity was fading away. The vision of the left eye, with its natural myopic astigmatism corrected, was found to be quite as good as that of the sound eye with its appropriate glass:—

V of right eye = $\frac{1}{10}$; with — 2.75 D spherical and — 1 D cylinder (axis at + 45° = $\frac{1}{8}$; and V of left eye = nil; with — 2.75 D spherical and — 1 D cylinder (axis horizontal) = $\frac{1}{8}$.

The pupil remained dilated, but this was attributed to the atropine; but at the present time (four months after the injury) the mydriasis continues, and there is some irregularity and eccentricity of pupil, notwithstanding the persistent application of eserine to which it readily responds. The lenticular cloud has quite disappeared, and the vision with glasses = $\frac{1}{8}$.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

THE BRAND TREATMENT OF TYPHOID FEVER.—At the Académie de Médecine M. Peter made a vigorous attack on the Brand treatment of typhoid fever, which he styled as brutal and dangerous. The cold bath not only affected the temperature, but had a well-recognised deleterious action on the whole organism. So much was refrigeration coming into fashion that he would not be surprised if some fine day a machine were made with a thermometer at one end and a pair of clamps at the other, which, when the thermometer would attain a certain degree, would, by automatic action, seize the patient and place him in a bath ready prepared! As to the statistics given by his German *compatriote*, he considered they were not exact, for the Lyons medical staff who had adopted the Brand treatment very generally reported that, under the cold bath treatment, the mortality rose two per cent. above the average. Referring to M. Pasteur and his recent discovery of the mode of propagation of contagious diseases, that is to say, by a microbe peculiar to each disease, M. Peter considered it to be an entirely new doctrine for him; yet he was inclined to believe it. But the next thing in his opinion was to find a parasiticide for each microbe, and as such he would suggest camphor, as having a less disagreeable odour than phenic acid.

COUSSO.—As *tænifuges couso* and the male fern have long enjoyed the reputation of being the most reliable, and

recourse has been had to one or the other when the parasite was to be dislodged. Some time back an enterprising chemist in Paris discovered a substance which he calls *Pelletierine*, and which acts most effectually on the *tænia*, expelling it in a couple of hours. It has one great advantage over the *couso* in that it is given in very small doses, and, consequently, less repugnant to the subject; 6 or 8 grains is a full dose, and often less will do. However, it appears that it is not entirely so innocuous to the health of the patient as the Abyssinian plant. If the alarming symptoms which followed the taking of eight grains, as reported in one of the medical journals, are to be attributed to its use, it should at least be given with caution. In the case in question the patient vomited and had diarrhoea, while the body became cold and exsanguine. It took an hour's work for the medical attendant to bring his patient out of the collapse.

PLEURISY OF THE DIAPHRAGM, or more strictly speaking, of the supra-diaphragmatic space, is always very difficult to diagnose, physiological symptoms being very incomplete, or altogether wanting. Gueneau de Mussy has indicated some signs which, however, are of good value in elucidating the question in favour of this variety of pleurisy. He discovered that the phrenic nerve is painful to pressure in the accessible points of its course between the two origins of the sterno-mastoid muscle. Also pressure on a circumscribed portion of the epigastric region awakens an acute pain. This spot is situated in a point corresponding to the intersection of two lines—one coming from the external border of the sternum, the other from the osseous part of the tenth rib. Gueneau de Mussy named this point the button of the diaphragm. Thus, whenever a patient is found to present these symptoms, the case, *ceteris paribus*, may be safely diagnosed as diaphragmatic pleurisy.

THE EXISTENCE OF METRORRHAGIA SIMULTANEOUSLY WITH LUMBO-ABDOMINAL NEURALGIA is too frequently observed to-day not to be understood by most medical men. It is sufficient, says the *Revue des Maladies des Femmes*, to establish clearly the relation between the exacerbations of the neuralgia and the return of the hæmorrhages to see the indication for the employment of the tincture of aconite, no matter what may be the lesions of the uterus. To rapidly suppress the hæmorrhage, one drop of aconite must be given every quarter of an hour in a teaspoonful of water, and that during six hours. The next day, if the amount of blood is not diminished, the same doses for the same length of time must be given again. The maximum daily dose necessary to arrest the hæmorrhage never exceeds forty to fifty drops.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND. SURGICAL SECTION.

Mr. J. K. BARTON, President, in the Chair.

THE Surgical Section met in the Albert Hall, Royal College of Surgeons. Mr. STOKES, Sectional Secretary, and Mr. THOMSON, General Secretary, were in attendance.

Mr. KENDAL FRANKS read a communication on

SPONTANEOUS DISLOCATION OF THE HIP,

Illustrated by two cases which he had himself observed.

Malgaigne, he said, has divided pathological luxations into two classes—first, simple luxations, in which, excepting alterations produced by the effect of time, the articular

surfaces have not been attacked by the disease; and, secondly, complicated luxations, in which the articular surfaces are essentially altered. To the former of these Volkmann has applied the term "Distensions-Luxationen," and to this form alone Mr. Franks alluded under the head of spontaneous dislocation. In reviewing the causes of these dislocations, a relaxed and distended state of the ligaments must be recognised as a condition which is invariably present. Hence the causes operate primarily in bringing about such a condition. These are (1) traction, (2) pressure, (3) paralysis, (4) muscular contractions, (5) essential causes (Malgaigne), (6) hydrarthrosis, pyarthrosis, &c. The first case recorded was an example of that form to which Malgaigne has given the name of essential relaxation, because absolutely nothing is known of its nature. In this form a joint "loses its solidity," and dislocation results without the pre-existence of any mechanical distension, without inflammation, and most frequently without pain. A child, *æt.* 5, was admitted into the Adelaide Hospital in January last. She had been confined to bed since the summer of 1882, suffering from acute disease of the left hip-joint. The acetabulum had chiefly suffered, and the head of the femur had probably passed partially through it, and in that position ankylosis had taken place. An abscess which had formed burst into the vagina and healed up. The limb remained permanently fixed in a semi-flexed position, abducted and rotated outwards. The child had been chiefly lying on this side, the right leg flexed, abducted, and rotated inwards, so that the knee lay behind the knee of the diseased limb. In August last, as she was being turned in bed by the nurse, a remarkable protuberance was seen behind the right anterior superior spine of the ilium. The child was questioned about it, but could not give any account of how it occurred. It gave rise to no pain. This protuberance was caused by the great trochanter, the head of the right femur having slipped out of its socket, and being easily felt on the dorsum of the ilium. No alteration in the parts has since taken place. The second case illustrated a dislocation of the hip taking place during an attack of acute rheumatism. A girl, *æt.* 15, was admitted into the Adelaide Hospital on the 10th October last, suffering from necrosis of the left tibia. She presented a well-marked dislocation of the right femur on to the dorsum of the ilium, the limb being shortened to the extent of 3½ inches. In May, 1879, she had an attack of acute rheumatism, from which she completely recovered. In the following February (that is, two years ago) she was attacked again with the same disease, which kept her in bed for ten weeks. The right hip-joint and the right shoulder were the parts chiefly affected. To alleviate the pain, pillows were placed under the hip and knees. When she tried to get out of bed after the disease had subsided, she found the right limb considerably shortened, so that she could only reach the ground with the ball of the foot. The right hip was deformed, and she now presents all the characteristic signs of a well-marked dislocation. The head and neck of the bone can be easily identified in this new position, and feel quite smooth and healthy. (Casts of these two cases were exhibited.)

Dr. HENRY KENNEDY called attention to a remarkable case of an athlete, who, two years ago, exhibited himself before the Pathological Society, dislocating at will his hip and several other joints. The muscles were exceedingly well-developed and powerful, as in ordinary health.

Mr. STOKES instanced another remarkable case, formerly under his care in the Richmond Hospital, in which a fall was apparently the exciting cause. The patient fell down stairs, sustaining a very severe injury, but he did not apply for advice till a fortnight had elapsed, when it was found he had sustained a dislocation on the dorsum of the ilium, which was with very little difficulty reduced by manipulation. Next day, to Mr. Stokes' surprise, dislocation again occurred, and was reduced, but luxation recurred three or four days in succession. He suggested in explanation that the fracture of the rim of the acetabulum had taken place originally, and portion of the bone was driven away from its normal situation at the time the luxation recurred.

Mr. BENNETT thought that too much importance was attached to the term "spontaneous." All pathological dislocations were spontaneous. A more important division would be as to whether the dislocations were complete or incomplete. The term "spontaneous" was a mistake for want of observation. Patients suffering from febrile phenomena were sometimes discovered at the end of an illness to

have a dislocation complete or incomplete, but probably complete, and to which the febrile symptoms were referable, instead of being general. In the deformity in question, he would not be surprised if the bones were still intact, but altered in shape.

Mr. WHEELER remarked that Prof. Dittel, quoted by Mr. Franks, had stated that without relaxation of the ligaments, spontaneous dislocation occurred, for instance, dislocation of the hip following recovery of dislocation of the knee-joint, but whether complete or partial dislocation, it was not stated.

Mr. FRANKS replied, concurring in Mr. Stokes' explanation of the case he had cited. In reference to Mr. Bennett's criticism of nomenclature, he confessed he had had difficulty in choosing a title for his paper. Perhaps it would have been better had he described the dislocations as simple spontaneous dislocations, to distinguish them from disease of the articular surface. He agreed, however, with Malgaigne, that the best line of distinction to draw was between dislocations due to simple relaxation of the ligaments, without any disease of the ends of the bone, and cases in which there was caries or some other disease on the head of the bone. Dislocations that occurred from distension of the ligaments formed a distinct group.

Dr. R. McDONNELL brought before the Section notes of
THREE CASES OF INJURY OF THE SPINE FOLLOWED BY
PROGRESSIVE MUSCULAR ATROPHY.

In all three cases there was little, if any, loss of sensibility. The patient was sensitive to tactile and thermic impressions. The wasting of the muscle was rapid and set in early after the injuries. The character and appearance, as well as the marked degree in which individual muscles were attached, showed, in the author's opinion, that muscular atrophy in these cases depended upon the same causes which produce individual muscular atrophy in infantile paralysis and paralysis of the Duchenne-Arun type—viz., myelitis affecting the large motor nerve cells in the anterior cornua of the spinal cord.

The PRESIDENT inquired what were the conditions present in the case that recovered?

Dr. SWAN, referring to the same case, asked the author if he believed that there was regeneration of the cells in the anterior horns?

Mr. BENNETT assumed that the object in bringing forward the cases was to establish the spinal origin as distinguished from that attributed by Roberts and Cruveilhier—i.e., localising the origin of the disease to pathological change in the spinal cord. That muscles were the prime organs in fault could be supported by a number of cases. Those of traumatic origin went to establish that the lesion was primarily of the spinal cord. Fifteen years ago a man was under the care of Dr. Fleming, in the Richmond Hospital, presenting phenomena exactly the same as in the photograph handed round, and the cause of the lesion was a blow of a steamer's hawser. Having made the post-mortem examination himself, he could say the lesions of the spinal cord were sufficiently overt and distinct to be recognised.

Mr. WHEELER mentioned a well-known case that was in the City of Dublin Hospital, under the care of Prof. Purser, suffering from Cruveilhier's palsy. The patient was a tall, gaunt man, who used to stand at Baggot Street Bridge, and had been driver of the Wicklow coach. His upper extremities were only held to his trunk by the levator anguli scapulae muscles, so that the posterior superior angles of his scapulae were pulled up close to his ears. He stood with his body thrown forward to prevent his abdominal viscera from falling forward, as all the abdominal muscles had disappeared. The palsy apparently originated from injury. He fell and hurt the back of his neck and spine. From the cast shown by Dr. McDonnell, it seemed that the flexor brevis abductor and opponens pollicis muscles were very much wasted. He asked, Could Dr. McDonnell assign any reason why the flexor ulnaris muscle and other muscles were not wasted in the same proportion? and if he had made observations in similar cases of the condition of the nerves down the forearm, whether their motor fibres were altered? With regard to Dr. McDonnell's second case, it appeared to him (Mr. Wheeler) that the trophic cells were not engaged, but only the connective tissue elements, and when it returned to its normal condition, the temporary influence it exercised on the cells ceased.

Dr. McDONNELL, answering Mr. Wheeler, first, as to how

the particular muscles atrophied, said in all of those that belonged to the group he was speaking of, it commenced in the spinal cord. If a group of those cells disappeared, it might be laid down as certain that the muscle corresponding with that group of cells would also disappear, and the nerves leading to that would wither away. In those cases which he had examined, the nerve fibres in the roots were found to be atrophied. The question was naturally asked, "Might it not begin in the muscle?" or, as Cruveilhier put it, in the nerve root, or in the trophic cells? Years ago he had himself asked Lockhart Clarke if he had had opportunity of examining cases in which, long after amputations, those cells had not been called into use, and when, for want of use, they had become atrophied. It appeared that in fifty or sixty cases which he had examined in Greenwich Hospital the cells in the spinal cord were found to be right. Evidence had been accumulated to show that the disease really began in the nerve cells and spinal cord. As to the pathology of the successful case, he did not see how it could, clinically speaking, be distinguished from the others, the patient presenting exactly the same appearance; but he was inclined to regard all inflammatory action attended with atrophy as a matter of degree.

The Section then adjourned.

Special.

THE MEDICAL ACTS AMENDMENT BILL IN THE HOUSE OF LORDS.

ON Thursday last this Government measure came up for a second reading, under the charge of Lord Carlingford, who referred to the fact that the present Government had appointed a Royal Commission to inquire into the subject of existing legislation with regard to the medical profession. That Commission was comprised of men of great eminence, amongst them being the great Judge who had so recently died (Sir G. Jessel), and who entirely approved of all the recommendations which the Royal Commission had arrived at. The noble Lord then glanced at the history of modern legislation on this matter, and said that the Act of 1858, which was still in force, was found after a few years' experience to be defective. Accordingly, in 1870, the Marquess of Ripon, who was the President of the Council, introduced into the House a Bill to remedy the deficiencies of the existing law; but that Bill, although it passed through their Lordships' House, failed to satisfy the House of Commons on the point of the direct representation of the medical profession on the Medical Council. The subject was again taken up by the Duke of Richmond, who introduced a Bill in 1878 and in 1879, which passed their Lordships' House in each of those years, but did not succeed in getting through the other House of Parliament, although that House appointed a Committee to inquire into the matter. Since that time the present Government had appointed a Royal Commission, and this Bill was based upon the report which that Commission had presented to Parliament. The real difficulty to be dealt with by legislation lay in the multiplicity, the variety, the uncertainty, and often the insufficiency of the medical licences which admitted persons to the Medical Register, and the only mode of dealing with this difficulty appeared to be by constituting in each of the three divisions of the United Kingdom a Board consisting of members of the present licensing bodies, which Board alone should have the right of testing and certifying the competence of those who were to obtain the legal right to practise medicine and surgery. The Bill stated that any person, male or female, passing the final examination provided by it—with certain exceptions, which he would mention hereafter—should be entitled to be placed upon the Medical Register. For the purpose of holding this examination, and for other purposes, the Bill would constitute a Medical Board in each of the divisions of the United Kingdom, representing each of the bodies now capable of giving diplomas. The number of these bodies might be increased or diminished from time to time by the Privy Council upon the motion of the Medical Council. The Bill provided that each of the Medical Boards should prepare schemes not only for the final examination, but for the previous qualifications of the candidates, both in general

and professional knowledge, and that those schemes should only come into effect when they had received the approval of the Medical Council and the Privy Council. It also provided that these Boards should aim at a uniform standard, and a system of uniform conditions as between the three countries. The Bill also aimed at improving the constitution of the Medical Council and lessening its numbers. That Council would, under the Bill, consist of six Crown nominees, of eight members chosen by the Medical Boards of the three parts of the Kingdom, and of four members elected by the general body of the medical practitioners of the United Kingdom. The Medical Council would be renewed every five years. Its duties would be to inquire at its discretion into the efficiency of the examinations conducted by the Medical Boards, and to exercise a general superintendence over those boards. The third part of the Bill gave the Medical Council discretion to recognise colonial and foreign qualifications. It was hoped that by this means our countrymen would in future be met with favourable reciprocity abroad, instead of the very unfavourable reciprocity to which they are now exposed in consequence of our inhospitable treatment of foreign and colonial men. The next part of the Bill contained improved provisions for preventing the fraudulent and deceptive use of medical designations by so-called medical practitioners. The Bill also dealt with the question of the expenses and funds of the Medical Boards. By the changes which he had indicated, it would be seen that there was to be a reform of the Medical Council or central body, and it was hoped that the effect of these changes would be to make the body more important and useful than it had been heretofore. One of the changes in its constitution would be the admission, in a moderate form, of direct representation of the great body of the medical practitioners in the country. The next change proposed was that the members of the Medical Council derived from the medical licensing authorities should be chosen not directly one by one by each of those authorities, but by the Medical Board of each division of the Kingdom. There was a great body of evidence before the Royal Commission in favour of this change. With regard to the Medical Boards, the only serious consideration was as to the proportionate numbers of the different medical authorities to be represented upon them. He hoped, however, that this point might be satisfactorily settled. The duty of the Medical Boards he regarded as the very essence of the Bill, and it would be for the general interest of the public and the profession to require these distinguished bodies to come in under the joint scheme proposed by the Bill. The Bill was full of provisions of considerable importance, which, however, it would not be necessary for him to go into at this stage. It was highly expedient that the question, if possible, should now be settled. Four years ago the Medical Council adopted a resolution to the effect that the continued uncertainty of legislation on the subject retarded the improvement of medical education, and was contrary to the interests of the profession and the public. That was perfectly true; and he hoped their Lordships would, by consenting to the second reading, take a step towards putting an end to that state of things.

The Earl of Aberdeen said that in Scotland there was considerable feeling in reference to the measure, and he had that day received a telegram from the Principal of the University of Aberdeen, stating that the feeling was unanimous on the part of the governing body that considerable amendment was necessary in the measure. In view of those amendments he had heard with considerable satisfaction that it was not intended to fix an early day for Committee.

The Earl of Milltown said the first point that the Colleges wished to press upon the House was the desirability of uniformity of education, examination, and fees, a matter which was not provided for in the Bill, some of the clauses of which he regarded as inconsistent with that idea. It was most desirable that there should be some controlling power, such as that of the Benchers over the Bar, and that there should be an affiliation of the medical colleges. As to the disposition of the surplus funds, he said that there was no proper provision made in the Bill, and the registration fee he thought unnecessary and vexatious. He doubted the expediency of admitting laymen as members of the Board, and did not think that Apothecaries' Hall, which was a trading institution merely, was entitled to representation.

Earl Cairns said all would agree that nothing could be

worse than that, in place of uniformity of education and qualification, there should be competition, not to give the best education, but to secure the greatest number of students. The main object of the Bill, he understood, was to prevent that result. There were one or two provisions which might appear at first sight to be matters of detail, but which in reality went to the root of the Bill, and he wished to call attention to it as it would in its present form affect University education in Ireland. Medical education in Ireland and Scotland differed, as their Lordships were aware, from that of England. As compared with Ireland and Scotland, only a small number of English graduates entered the medical profession—in Ireland the number was very large. Speaking in round figures, during the past five years 40 or 50 per cent. of those on the Medical Register in Ireland or Scotland took their position in respect of their University education. They did not come upon the Register with their medical qualification alone, but with the proof that they had a thorough general education. Nothing, he thought, would be further from their Lordships' wish than to injure a system which had been productive of such excellent results. The Bill in one sense took away a considerable amount of the protection which the Universities had. At present the Irish and Scotch Universities were able to give a medical degree which entitled the person who received it at once to come upon the Register as a practitioner, and the Bill proposed that the practitioner should not come upon the Register until he had undergone an examination by the Medical Board. That was an enormous sacrifice to call upon the Universities to make, and they might well say in surrendering their authority that care should be taken that no unnecessary injustice should be done to them. There was one way of keeping the Universities in the position which they ought to fill, and that was, by giving them a strong position upon the Medical Board. The Universities of England, if any difference was made, should have less power than those of Ireland and Scotland, because they passed a much smaller number of men into the profession. On the English Board there were fifteen members, of whom the Universities appointed eight; on the Scotch Board there were eleven members, of whom the Universities appointed eight; and on the Irish Board there were eleven members, of whom only four were appointed as the University representatives. This, he thought, must be a mistake. He thought this objection would be satisfactorily met by taking from the representation of the non-University bodies and increasing that of the Universities, and he hoped the Lord President would agree to this proposal. He thought also the provision as to the power of the Privy Council virtually gave the absolute power into the hands of the Executive Government, and this he considered a mistake. He should have preferred to see these powers exercised in the ordinary way by Order in Council, which must be laid on the table and approved in the usual way. With these alterations he should have no objection to the Bill, but he could not say that he should be glad to see it pass into law in its present form.

Viscount CRANBROOK called attention to the provision in the Bill which proposed, under a penalty of £20, to prohibit the use of foreign medical titles. It was no uncommon thing for practitioners possessing the licence of the College of Physicians or the College of Surgeons to take a degree from some foreign University, and frequently these were only given after severe examination. It seemed to him a strong measure, especially in regard to those who already held these titles, to say that they should not use them. It would simply mean that they should say to their friends and patients, You must not call me doctor any longer, or I shall be liable to a penalty of £20.

Lord BALFOUR of BURLIGH complained of the position in which this Bill placed the Scotch Universities. The noble Lord had said it was merely a matter of feeling, but he maintained that it was not so. It was all very well to say that they were not asked to give up more than the English Universities gave up, when perhaps the English Universities did not give more than 50 degrees in medicine a year, as against 3000 or 4000 students in the Scotch Universities. He was by no means satisfied that the new degree in medicine which the Bill set up in the licence of the Medical Council would be advantageous to the cause of medical education, since it would have the effect of lowering the standard of medical education throughout the country. He thought the interests of the existing Universities would best be served by appointing inspectors to sit with the present examining bodies. The Earl of CAMPERDOWN, as Chairman of the Royal

Commission which had recently sat on this subject, acknowledged the invaluable assistance which they had received from the late Sir George Jessel, and spoke of the great loss which the country had sustained by his death. He was committing no breach of confidence when he asserted that the decisions of the Commission met with his unqualified approval. He hoped that the present attempt to deal with the matter would be successful. The question was one which could no longer be left alone, and owing to circumstances they found that they must either allow the licensing bodies to go on increasing indefinitely, or they must restrict their number. The Commission had recommended, and he was glad to see that his noble friend had accepted that recommendation, that there should be one sole licensing body, and that the Medical Council. So far from seeing any objection to that change, he thought it would work very much in favour of the medical profession. In his opinion the number of members of the Board allotted to the Universities in England was by no means in fair proportion to those allotted to the corporations. In Scotland he thought the allotment was fairer; but in Ireland he thought it required serious reconsiderations. With regard to the desire of the Scotch Universities to be exempted from the operation of the Bill, he pointed out that to concede this point would strike at the root of the measure.

Lord CARLINGFORD having intimated that he intended to propose a clause in the Bill which would have the effect of not interfering with qualifications under which persons were legally practising at the time of the passing of the measure, The Bill was read a second time.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, APRIL 11, 1883.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND MEDICAL REFORM.

It is very much to be regretted that in a most critical period of its history the Royal College of Surgeons in England should, by the ill-advised action of its governing body, have been thrust into the position of antagonism towards reform it occupies at this moment. There are many thousand members of the medical profession who justly regard the College as the home of enlightened surgery and the legitimate conservator of all that is

best and wisest in connection with it; but we have no hesitation in asserting that a vast majority at least of such practitioners, will view with real grief and distress that obstinate persistence in perverted opinions which has culminated in the issue of a "Statement" of objections to the Medical Acts Amendment Bill just put forward by the Council of the College. This curious document bears the signatures of Mr. Spencer Wells, as President, and of Messrs. John Marshall and Cooper Forster as Vice-Presidents of the Royal College of Surgeons, and in a confused and rambling manner proceeds to dwell on the supposed injury inflicted on the corporation they represent by the provisions of the new Bill. Analysis of the "Statement" brings out in prominent relief the principal complaint of the objectors, to the effect that substitution of a single qualifying examination for the multitudinous tests now existing will assuredly diminish the importance of the College of Surgeons as a body empowered to confer a registrable qualification to practise. Nothing less than amazement will be excited by the knowledge that at this stage of events any association of gentlemen engaged in the work of examining students about to enter on professional practice could give utterance to the objection that "the new authorities and powers proposed to be created by the Bill could not possibly realise better examinations, and therefore better results, for medical education, for the medical profession, and for the public," than the Royal College of Surgeons! And this is seriously put forward in support of pretensions which, if admitted, would leave to a corporation notoriously negligent in its duties in at least one important respect—that of examining in midwifery—continued power to play the rôle of dictator so peculiarly and successfully assumed by it in the past.

By its own admission, however, the College is in no way entitled to the consideration it presumes to claim. Leaving, for the moment, the question of pecuniary loss that will be entailed by the "disability" clause of the Bill, in which it is enacted that "lowest titles" conferred by corporations sending representatives to the medical boards shall be excluded from the Register, the following significant observation contained in the "Statement" deserves notice:—"The Council of the College of Surgeons cannot see its way legitimately to increase the examination for its membership; and it cannot fail to foresee that were that diploma deprived of its character as a qualifying title it would, after no great interval of time, cease to be sought for." The autocratic College pleading *ad misericordiam* is a novel and an interesting exhibition; but the unwonted appearance must not be permitted to blind our vision to the real object underlying the pitiful outcry, and which is nothing more nor less than a preposterous demand for special and unique privileges, in possession of which the College may be enabled to bid defiance not only to competition, but even also to the medical board. In effect, the College seeks to be endowed with the privilege, to be retained by itself above all existing corporations, to give a qualification of equal legal weight with that to be conferred by the medical board, and carrying the same right to registration! Has the Col-

lege of Surgeons done anything to entitle it to such exceptional advantages? Is its demand in any way justifiable? Surely the answer to both these inquiries is the same—an absolute negative.

In the future the membership of the College will occupy the same position as that of any other ornamental qualification. If it possess a value equivalent to the trouble entailed in its acquisition, it will be sought for; if not, it will most deservedly sink into the obscurity dreaded by the Council.

It is not ungenerous to suppose that the Council of the College has been keenly alive to the fact that, under a new régime now happily dawning, financial questions will seriously disturb the serenity of its horizon. It finds itself, for the first time, relegated to a position of mere equality as compared with other licensing bodies, and naturally enough a flutter of distress is visible amongst its members. Accustomed to regard itself as holding of right the position of premier licensing institution in this country, a right, too, most ostentatiously paraded in the "Statement," the College is unwise enough, at this crisis, to adopt an arrogant tone of demand; it is fitting, therefore, that its untenable claims should be boldly exposed. Something more than indulgence would be required to pass unrebuked many of the expressions contained in the document; but perhaps the most striking evidence of an unbalanced judgment is afforded in those sections which are devoted to criticism of the powers to be conferred on the medical boards. We are informed that "to endow these medical boards elected by the medical authorities with such independence and authority as is contemplated in the Bill would be to create, by the action of the already constituted medical authorities, new and unnecessary *outside authorities equal in influence to those authorities themselves.*"

In this quotation the italics are our own; but the "Statement" further complains that the authority of the boards will even be *superior* to that of the present licensing authorities, inasmuch as the former will be invested with power to confer a registrable qualification, whereas the latter are destined to be deprived of such agreeable and profitable distinction. Were it not that dissection of the rambling sentences of the "Statement" does really discover the monstrous evidences of retrogression we have instanced, there would be difficulty in convincing any one of the extent which to the College of Surgeons has been committed by its nominal governors. We do not, however, for a moment imagine that the utterly indefensible opposition thus formulated is reflected by the Fellows and Members as a whole; we feel sure they will indignantly repudiate the objections registered in their name, and that they will in overwhelming numbers condemn the narrow prejudice which seeks to cherish a single interest at the expense of general professional progress. The worst enemies of the Council of the College could not have desired that it should commit a graver blunder than is embodied in the "Statement;" its best friends will pray that its efforts to prevent reform may be as unsuccessful as they are unworthy.

THE TUBERCLE BACILLI WAR.

WHEN, about twelve months ago, Koch first made known his celebrated discovery of the bacilli of tubercle, the scientific medical world received the announcement in silence. The silence was not that of indifference, however, but rather related to that produced by shock at the receipt of a stupendous piece of news. The subject was entirely novel to nearly all workers, and they made no reply, because, as has been ingenuously said, they "had no reply to make." They wanted time. When in April of last year Koch demonstrated the bacilli at the Medical Congress at Wiesbaden, he had it all his own way. Again they had no reply to make. His experiments had been tedious, much time had been required to reach any definite result, and much would be required in order to go over them for the purpose of "checking" them. Men of science were not, however, idle. They immediately set to work at the problem before them, and in the course of a few months, here and there one felt himself to be in a position to speak. Of the number were Schottelius, Formad, Spina, Ephraim Cutter, Rollin, R. Gregg, Schmidt, Crämer, and Balogh. More recently, Dr. Ziehl, of Heidelberg, has been claimed as an ally by the opponents of the views of Koch and Ehrlich. Spina, an assistant to the well known Stricker, of Vienna, is the only one of them, however, who has professed to repeat the cycle of experiments of Koch, and the results arrived at have been so very different from those of the Berlin investigator, that on their publication they immediately challenged the attention of both that gentleman and Ehrlich.

Spina's attack consisted first in a denial of the inoculability of tubercle; second, in a denial of the very existence of tubercle bacilli, as distinguished from the bacteria of decomposition; and third, in a denial that the bacteria of Koch were impermeable to acids.

In regard to the first count, Spina has been supported by his chief—Stricker, who takes upon himself the responsibility of all that his assistant has said on this part of the subject; indeed, he is quite willing to share the responsibility of all that Spina has given utterance to, and this after hearing Koch's reply, or rather after the publication of Koch's reply. Stricker relies on earlier experiments on the inoculability of tubercle, made in various latitudes, London, Berlin, Turin, and Philadelphia, which have shown, as he claims, that tubercle may be originated by various indifferent substances. He points in proof of this to experiments performed in London by Sanderson, in which he himself took part, and to others performed by himself alone. This of Stricker's we think a "palpable hit." Supposing for the moment that all Koch's inoculations with purely cultivated bacilli result in the production of tubercle; before the bacilli can be accepted as the sole cause of the disease, he must show that it never arises in any other way than by that of inoculation by tubercle germs. This has not yet been done. Spina's inoculation of two rabbits with cultivated virus had merely negative results. Both died, it is true, but at a date that rendered it quite probable that, as suggested by Koch himself, they died of phthisis contracted through confinement in impure cages. Koch replies to all his critics in a lengthy com-

munication to the *Deutsche Med. Wochensh.*, No. 10, and reprinted in *extenso* in the columns of the *Wiener Med. Zeitung*. He follows Spina's experiments, and claims that they were not likely to result in anything definite. Spina took a small piece of tubercle, painted it over with a solution of corrosive sublimate—the most powerful destroyer of bacilli (Koch)—and then expected it to be as virulent as before. Koch himself, on the other hand, painted the surface of a piece of human tuberculised lung, then cut a clean surface below this, with a knife previously rendered aseptic by heating, and from this obtained his results. It is perfectly clear that the two experiments are not parallel, and that Koch is justified in declaring Spina's to be of no value.

In regard to the second count, viz., that in which Spina denies that Koch's bacilli are distinct from those of decomposition, Koch again declares that Spina has not followed his method of manipulation—that instead of applying the re-agents to the thinnest possible layers of sputum, he has applied them to a thick mass, which it has been impossible for them to permeate, or, at the most, at the edges only. Then again, Spina, in his examination microscopically, has used only a system for water immersion, instead of the oil immersion with Abbe's light. Here again, it seems that Spina has been wrong, and that, doing as he has done, it was not likely that he would reach the same conclusion as Koch. Indeed, the latter does not hesitate to say that he has doubts as to whether Spina has ever seen the tubercle bacillus.

The third count, that in which Spina denies that the bacilli of Koch are impermeable to acids, seems to be passed over by Koch, who seems to think it sufficiently answered in his declaration that Spina has never seen the tubercle bacillus, in which case of course, any statement as to its re-actions would be without foundation. Ehrlich, however, does not pass over the objection in silence.

The whole subject was under discussion in Berlin at the meeting of the Society for "Medicine," held on the 5th of last (March) month. Ehrlich read a paper, in which the line of defence against Spina's attack was identical with that adopted by Koch. In the discussion which followed, he was asked by Herr P. Guttmann if he had repeated Spina's experiments. To this question he gave no direct reply, but, as the *Allgem. Wiener Med. Zeitung* says, he slunk aside, and contented himself with expatiations, the sense of which his Vienna critic failed to grasp. During the course of his reply, however, he made some important admissions—admissions which the Vienna journal has chosen to consider a retreat, and a justification of the heading to a leader on "Ehrlich's Retreat." Ehrlich is reported to have said: "The fundamental error in Spina's manipulations of his preparations rests in this, that he has not washed them with nitric acid, but only moistened them." He says further, "that it is of advantage, in order to prevent the action of the nitrous acid, which is given off from the nitric, from acting on the fuchsin-sputum preparations, to allow contact with the acid only for the shortest possible time, and to use the thinnest possible preparations." His so-called retreat is supposed to be

contained in the following words—not reported in the *Deutsche Med. Zeitung*, however: "By uncolouring in this manner, the possibility arises—nay, the probability—that the greater portion of the bacilli present will be destroyed. For this reason, I maintain that the treatment (of the preparations) by nitric acid should continue for as short a time as possible."

That this is an important admission cannot be denied, but we do not think it amounts to a surrender of the whole position. That taken by Koch and Ehrlich is that the bacilli of tubercle can be distinguished from all other bacilli by the test, that if you wash tubercle bacilli stained by methyl-violet with acids, say nitric acid, they will still remain coloured blue, whilst all other bacilli will have become colourless. That taken by Spina is that, if you take any kind of bacilli, Koch's or the bacilli of decomposition stained with methyl-violet, and allow them to remain in contact with nitric acid, the blue colour will be destroyed. It would seem, if these positions are correctly stated, that Koch and Ehrlich have omitted, in their description of the mode of manipulation, to put a limit to the time during which the preparations should be exposed to the action of acids. Not having anything to guide him on this important point, Spina has evidently allowed his acids to act for a longer time than Koch and Ehrlich have done, with the result that he has reached conclusions totally different from theirs. He has thus drawn attention to an important omission on their part, and by doing so has deserved the thanks of investigators. We do not think he has upset and completely demolished the whole of Koch's teaching; he has shown, however, that it needs revision in some important particulars. We are promised further contributions on the subject on the part of Spina, who is at present employed in investigations, and Stricker, in making the announcement at a meeting of the Royal Society of Physicians of Vienna, held on the 16th of March, takes occasion to say that he himself "has such great confidence in the microscopical skill of Spina, that he hopes the latter will make clear the standpoint of those gentlemen who, without repeating his experiments, have published adverse criticisms on them." It would take too much space to follow Koch through his treatment of all his critics: sometimes it is simply severe, at other times bitterly sarcastic—as when he expresses the hope that Sternberg, who doubts the existence of tubercle bacilli because he has not been able to find them, "has in the meantime convinced himself of his error," and dismisses him with this single contemptuous utterance. He maintains throughout that if investigators have failed to obtain results similar to his own, the fault has in every case been their own; they have either not had sufficient manipulative skill, or they have worked with imperfect appliances, or they have failed to comply with all the conditions laid down by himself.

THE MEDICAL ASPECT OF THE TELEPHONE.

EVERY profession and calling has its drawbacks, and the most enthusiastic admirer of medicine would hardly deny that a very serious one in its case is the constant

preparedness which it entails, and the everlasting liability to sudden calls in and out of season. The lawyer, the banker, or the merchant, have their hours of toil sharply defined, and, when the day's work is over can, with an easy mind, betake themselves to their well-earned repose. Not so with the medical practitioner, whose clients take ill, or imagine that they take ill, at all hours of the day or night, and unless his speedy attendance can be procured, will probably have recourse to other assistance, and to his *pro tanto* professional injury.

In a calling so liable to sudden and immediate summonses at all hours, and whose members are mostly distinguished for scientific taste, it might well be imagined that the latest resources of scientific progress would be in common use—but it is sadly otherwise. In *Gil Blas* we read that when a fit of apoplexy occurred a maid servant was sent to knock at the physician's door; and so it is here even to the present day. If a case of illness happens at night, a servant, a letter, and a slow night cab still form the medium of seeking medical aid. Sometimes the physician lives at the other end of the city, a cab is hard to be found, and calling him in is often a business of two or three hours; too often when he comes he finds that the alarm is a false one, and that, if he had been able to hold a short consultation through the telephone, he could have arranged everything in about three minutes, and without leaving his room.

In most large cities, like London, Edinburgh, and more recently in Dublin, we have an admirable telephonic system, which is spreading by leaps and bounds, among our mercantile, legal, and financial brethren. Every merchant, every shopkeeper of any position has now his telephone. All first-class solicitors are similarly provided at their offices, and in addition have access to a set of telephones at the law courts. They are thus able to tell how cases are getting on, and to instantaneously communicate with each other. It may be observed that, different from telegrams, telephonic conversations are, with proper caution, as secret as a conversation between two persons in a room with double doors.

All the telephones, legal, mercantile, and financial, in a city-run to a great central ganglion, where the *modus operandi* is as follows:—A, a solicitor, wants to speak to B, another solicitor, living perhaps three miles off, about the proposed settlement of a suit; he rings up the clerk in the central exchange and says, "connect me with B No. 220." The clerk replies that this is done, and A's and B's wire now form a straight and unbroken communication between them. Having settled this matter, in doing which he can recognise B's voice, he gets himself connected with C, the client whose case was a question, and, let us hope, announces to him that the suit is settled. In this way he arranges business requiring personal interviews in about as many minutes as it would take hours were he to hunt up the various individuals.

The extensive and increasing use of this latest practical benefit of modern science is practically restricted to commercial operations, but we ask, why should it be so, and why should not the medical profession take up the telephone? At present the Dublin Telephone Exchange is

not open at night, or upon Sundays or Bank Holidays ; but we are assured by its enterprising promoters that they will take an early opportunity of keeping it open day and night. They would at once do so if any reasonable medical support were obtained.

To hospitals the telephone would be invaluable ; and it will hardly be believed that in but few of the London hospitals, and in only one in Dublin (Cork Street Fever Hospital) is it used. In a properly-arranged hospital all the members of the medical staff and the institution itself should be on the Exchange. They could thus communicate with the hospital, and with each other. If an accident or an urgent case came in, the resident medical officer could discuss and describe the occurrence with the visiting medical attendant, and thus the work could be accomplished twice as well as at present, with about half the present labour and consumption of time. If the first visiting medical officer was not at home, the telephone would at once connect with another, which would be a great improvement upon the porter driving from house to house in a slow cab.

We believe that there is a great future open to the medical telephonic exchange. At present it is confined to a few hospital surgeons and the majority of the leading pharmacoutists ; more will soon follow. Irrespective of the obvious convenience of instantaneous communication between hospitals and their surgical staffs, and the evident benefit to accident patients in having the responsible surgeon within immediate call, there is a direct gain to the practitioner which will, we doubt not, come home to his comprehension. With the telephone in his residence, he is—so to speak—always at home. If a private patient presents himself at the practitioner's house, he can, in a moment, be called from his hospital or school, and thus secure a case which would otherwise certainly go elsewhere. Appointments can be made for him in his absence to call anywhere "on his rounds," and he can himself communicate from any part of the city to his own house the arrangements he may find it necessary to make. If he needs instruments or medicines for any special case he can order them without delay or trouble. We believe that before ten years there will be a telephone in every hospital, in every practitioner's house, and, for the matter of that, in every comfortable family. This will practically supersede the night bell, the slow messenger, and the letter requiring hours before a reply can be had. Some years hence we will probably wonder how we got on without telephones.

Notes on Current Topics.

The Vivisection Bill.

THE second reading of a Bill introduced into the House of Commons with the object of abolishing every form of vivisection in this country, ended last week in that most ignominious of all methods of defeat—a "talk out." Small, however, as the chance of a successful issue was, it may very properly be considered that the mere attempt to place further restrictions on research is a subject to excite our feelings of distrust anew, and to animate us afresh to pur-

sue the task of enlightening the public respecting the evil that is sought to be done to them in the name of humanity. Little by little the people are growing to appreciate the real value of all that cant and misrepresentation which is current with anti-vivisection agitators for argument and description. At meeting after meeting resolutions condemnatory of science are rejected in favour of those approving of progress ; and always it has happened in recent times that, when medical men competent to expound the necessity and advantages of the experimental method have troubled to refute the mis-statements and calumnies of paid agents of anti-vivisection societies, their efforts have been successful in completely turning popular indignation against the opponents of research. In the debate which took place on Mr. Reid's Bill, Dr. Playfair spoke against it, and seconded the motion to reject it moved by Mr. Cartwright. Sir William Harcourt and Sir J. McKenna also spoke against the measure, the former insisting that no cause for altering the law as it stood at present could be made out. As a result of the discussion, the nuisance of anti-vivisection in Parliament is crushed for another session at least.

A Twentieth Qualifying Body.

By a supplementary charter, dated March 20, 1883, the Victoria University, Manchester, is empowered to grant degrees in medicine and surgery, so that, in place of nineteen licensing bodies, the United Kingdom now boasts no fewer than twenty separate corporations entitled to grant a legally registrable qualification to practise the profession of medicine. At a meeting of the Victoria University Court recently, the question of appointing examiners for the new degrees was considered, and a resolution empowering the council to elect such examiners, both external and from the University lecturers, was approved.

Historical Physiology.

ON Tuesday, April 3, Prof. J. G. McKendrick, M.D., delivered the first of a series of ten lectures on "Physiological Discovery" before a large and appreciative audience, at the Royal Institution. The subject of this first discourse was "The Circulation of the Blood : a Problem in Hydrodynamics." In it the lecturer sketched the history of the circulation, and of the manner in which experimental illustration had sufficed to overcome many of the worst difficulties of observation. Dr. McKendrick pursued the plan of giving a biographical account of the important contributors to our knowledge, from the earliest time onwards ; and in his review of the circulation, Galen, Vesalius, Fabricius, Harvey, Malpighi, Thomas Young, and the chief of the modern discoverers were noticed. This lecture derived additional interest from the exhibition of numerous instruments employed in physiological investigation to demonstrate the velocity and pressure of the blood in the circulation. A demonstration of the gradual growth of the sphygmograph and of the generally-accepted theory of the circulation as propounded by Weber, concluded a most valuable and instructive lecture.

It is announced in the official *Gazette* that Her Majesty has been pleased to confer the honour of Knight Commandership of the Order of the Bath upon Dr. Lyon Playfair, M.P.

The Baths of Bath.

THE city of Bath has during the week past been the scene of an important and interesting ceremony in connection with the widely known baths for which it is famous. Animated by a spirit of anxiety to make the advantages derivable by their visitors as great as possible, the Bath City Council has expended a very considerable sum of money in improving and extending the historical baths of the town, and they were formally reopened on Wednesday by the Mayor, Mr. H. Cossham. New baths have been erected at a cost of £14,000.

Leeds General Infirmary.

AT the annual meeting of the friends and supporters of the Leeds Infirmary, held last Wednesday, the weekly board presented a report which shows the importance and extent of the work done in connection with the institution, while also it exhibits a satisfactory state of finances in comparison with which the desperate condition of many London hospitals markedly contrasts. The receipts for the year 1882 from all sources reached the sum of £15,107, the expenditure being £13,298 7s. 2d., of which amount £734 8s. 10d. was for extraordinary purposes in the way of building extra accommodation for the resident staff of the hospital. The number of in-patients treated was 3,392; of out-patients 15,873, an increase of 1,230 over the number for 1881. The average cost of each in-patient amounted to 19s. 10d. per week on all charges, and of each out-patient 1s. 4½d. We are glad to be able to congratulate the executive of this hospital on the satisfactory nature of the report, which plainly indicates an efficient and economical service.

The London Hospital.

THE affairs of the London Hospital are approaching a most critical period, the sustentation fund of £15,000 per annum provided for five years being about to lapse, and unless some mode of meeting the deficit of income thus threatened is devised, a considerable portion of the building will have to be closed. The reliable income of the charity is less than £15,000 per year; its expenses during the maintenance of its full complement of beds, 790, about £47,000; and the prospect now before the poor of the East End of London is a disheartening one unless a way out of the impending trouble can be found. The hearty good will of every warm-hearted sympathiser with distress will be called forth to wish for some speedy and sufficient solution of the difficulty.

The Meeting of the British Association at Montreal.

A CIRCULAR has been issued by the Executive of the Association in which the arrangements for its meeting at Montreal in 1884, so far as they can be anticipated, are set forth.

The circular includes a letter from Sir A. T. Galt, High Commissioner for Canada, resident in this country, containing information as to the probable expenses that will be involved in attending the meeting, every line of which bears evidence of the generous hospitality the colonists are prepared to accord. In the first place, in respect to the cost of the journey to and from Montreal,

the Committee offer to arrange fifty free passages for the conveyance of the officers of the Association whose attendance at the meeting is indispensable. Beyond this it is prepared to devote the balance of £3,000 either to securing to a number of *bond fide* members passages at the single rate—about £15 10s.—for the single journey, or for a general reduction of the fares as far as the funds will admit. Arrived at Montreal, the Committee are willing to give assurance that free entertainment will be provided for at least one hundred and fifty, and probably for all others who may attend. But even those who may scruple to accept such free hospitality are told that the tariff of the Montreal hotels ranges between two and a-half and four dollars a day inclusive, whilst private accommodation may be obtained at much lower prices than in England. As to proposed excursions, Dr. Starry Hunt says that the Grand Trunk, the Canada Pacific, and the Intercolonial railways will furnish free transport over their lines from Nova Scotia to the North West. The Canada Pacific will also arrange an excursion to the Rocky Mountains, and the Grand Trunk one to the Great Lakes (including Niagara) and Chicago, while the South Eastern Railway will do the same for the White Mountains and Portland and Boston. For an excursion of this kind, occupying three or four weeks, it is estimated that a sum of £20 would be required for hotels, carriages, and other incidentals.

Arbitrary Proceeding against a Workhouse Medical Officer.

WE cannot help feeling that the manner in which the Local Government Board and the guardians have finally, as they trust, settled their troubles in connection with the Atcham Union Workhouse (Shrewsbury) is not calculated to give a feeling of security to the present officials of the union, or to others who have studied the case at a distance. We have not space to discuss from the beginning the painful circumstances under which the master and matron and the medical officer were requested to resign by the central authority without the slightest charge being proved against them except that they were not on good terms with one another. Nor need we discuss the motives of the guardians who granted a pension which may or may not be confirmed by the central authority in one case, and almost unanimously refused it in the other. That is a matter of very small importance. It appears, however, desirable that at this juncture a voice should be raised on behalf of the profession against such an arbitrary proceeding as that pursued against Dr. Whitwell, the workhouse medical officer. We repeat that we are not disposed to reopen the case, but we must protest against the theory that the medical officers of unions are to be treated as if they were in any sense on an equality, either official or social, with the other officers of the workhouse. The medical profession is one which is justly regarded in this country with the highest possible respect and esteem. Its members are educated gentlemen, and are accustomed to discharge their arduous and delicate duties with zeal and energy, whether their patient for the moment be peer, peasant, or pauper. The office of a workhouse doctor is especially arduous and irksome when its duties are diligently performed, for he is compelled by the laws of

his profession to see that his patients receive all the attention and care which their cases require; and yet he has no official power to supply any necessity, save by intimation to the proper authority, which intimation may or may not be disregarded. In a hundred different ways the position of a workhouse doctor is irksome and disagreeable. It can only be made endurable when he is treated with the courtesy and consideration due to one who is a gentleman by his profession, and whose zeal on behalf of his patients is rarely lacking in these days. Dr. Whitwell may rest assured of the sympathy of his professional brethren, and the vote so unanimously accorded him last week at the meeting of the Poor-law Medical Officers' Association may be taken as indicative of the feeling of the entire body.

The Hart Testimonial.

It will be in the recollection of our readers that a fund was set on foot last year for the purpose of presenting Mr. Ernest Hart, M.R.C.S., editor of the *British Medical Journal*, with a testimonial for his services in that and other capacities to the profession. This testimonial has taken the form of a portrait of himself, painted by Mr. Frank Holl, R.A., whom the committee commissioned with the work, and who has been completely and singularly successful. Yesterday (Tuesday) afternoon the presentation of this portrait to Mrs. Hart took place, at the residence of his Grace the Duke of Westminster, by Mr. Spencer Wells, F.R.C.S., President of the Royal College of Surgeons of England, treasurer to the fund, on behalf of the subscribers, a large number of whom were present on the occasion. Mr. E. Noble Smith, F.R.C.S., has acted throughout as hon. sec. to the fund, and to his energy much of yesterday's success is undoubtedly due.

Climatic Influences on Mortality.

THE sudden rise in the rates of mortality due to climatic influences was very marked a few days ago, during the prevalence of strong east winds. In every large town their influence is demonstrated by an increased death-rate, and whereas many districts boast at this season of the year a mortality ranging from 12 to 20 per 1,000 of their population, the minimum for the week ending March and beginning of April was 20, and the maximum 43 per 1,000. In London the excess over average was 262; and in Glasgow, Dublin, Manchester, Halifax, and Birmingham an even more marked excess was reached. Elderly people, infants, and persons with chest troubles were the principal victims who succumbed; and it may be noted that there was almost an immunity from diseases of the zymotic class, but one death throughout the United Kingdom being reported from small-pox, and exceedingly few from fevers. The rise, however, from the before-mentioned causes will be readily seen on comparing the following figures with preceding weeks. The annual rates of mortality for the period referred to in the principal large towns of the United Kingdom, per 1,000 of their population, were:—Edinburgh 20, Bradford 21, Leeds 23, Cardiff 24, Norwich, Bristol, Portsmouth, Huddersfield, Birkenhead 25, Newcastle-on-Tyne, Salford 26, London 28, Sheffield, Nottingham, Derby, Brighton 29, Hull,

Liverpool 30, Sunderland, Plymouth, Bolton 31, Preston 33, Birmingham, Oldham, Blackburn 34, Wolverhampton, Leicester, Halifax 35, Glasgow 36, Manchester 39, Dublin 43.

A Volunteer Medical Corps.

WE have read with much interest a circular on this subject by Surgeon-Major Evatt; but while agreeing with its author on the advantage of instructing as many as possible in ambulance duties and bearer drill, we cannot help thinking that the ever-changing classes of medical students would be the least fitted from which to form a Volunteer Medical Corps, whose most necessary attribute ought to be a certain degree of permanence. The number of recruits that would be annually required to keep such a transient corps in existence would be very large, and the labour entailed by the repeated instruction of new comers very great. The existing system of instructing so many men per company in each Volunteer corps already enrolled has, at all events, the advantage of bringing the members within reach when required, and no doubt the number of these might in most cases be locally increased by enlisting in the work many who would be willing to undertake the duties of a Volunteer Hospital Corps, though not disposed to assume those of a fully-trained Volunteer. If the proposal of Surgeon-Major Evatt be successfully carried out, it will confer much benefit on the Volunteers. We only doubt its feasibility, not its value if accomplished.

A meeting of representatives of the London medical schools and of surgeons connected with Volunteer corps, in furtherance of the above, will be held this day (Wednesday) in the board-room of the Charing Cross Hospital, at 8 p.m. Surgeon-Major Evatt will introduce the subject.

Rip Van Winkle.

A LONDON medical contemporary publishes on Saturday last the following remarkable discovery: "The Government Bill introduced into the House of Lords stands for its second reading in that House on Thursday this week. But as it has only the ninth place on the business paper, it must be held doubtful whether it will be reached." This information would be interesting but for the fact that the Bill had been read a second time two days before, and was the only order on the House of Lords' paper, except a few formal stages of private Bills. If the rest of the observations of our contemporary are written under this sort of inspiration and knowledge of the subject, they must be indeed luminous.

Pharmacopœia Revision.

AT the last meeting of the Council of the English Pharmaceutical Society, it was resolved: "That inasmuch as the Medical Acts Amendment Bill introduced into the House of Lords contains no provision by which pharmacists shall be empowered, conjointly with members of the Medical Council, to revise and prepare future editions of the British Pharmacopœia, the Committee be authorised to take immediate steps with a view to remedy this omission."

THE Mayor of Brighton (Mr. Alderman Cox), in forwarding last week to the treasurer the proceeds of the ball given in aid of the Sussex County Hospital, generously added sixteen guineas out of his own private purse to make up the amount to fifty guineas.

SIR CHARLES DILKE's answer to Mr. Burt in the House of Commons on Friday last—that in the present state of public business he could not hold out any hope of the introduction of a measure in the present session with reference to the abrogation of the Vaccination Acts—will scarcely satisfy the anti-vaccinators.

It is understood that St. George's Hospital, London, will shortly come in for a legacy of £20,000. The amount is to be invested, and the interest only will be available for maintenance purposes. The testator has done wisely in so directing it; the reduplication of wards, without the money to support them, has plunged many an institution of late into serious trouble.

ANOTHER instance of a large bequest being given with the stipulation that it shall be capitalised and the interest only used, is that of the residuary bequest of Mr. Duncan Vertue, who has left some £90,000 to the Edinburgh Royal Infirmary. Managers of hospitals possessed of the building craze must not be surprised at the imposition of such stipulations.

WE are informed that the Medical and Surgical Scholarships and the Duckworth Nelson Prize for Medicine and Surgery at the London Hospital have this year been awarded as follows:—Medical Scholarship, Mr. A. T. Schofield; Hon. Certificate, Mr. P. C. McD. Howse; Surgical Scholarship, Mr. P. C. McD. Howse; Hon. Certificate, Mr. O'C. Jones; Duckworth Nelson Prize, Mr. P. C. McD. Howse; Hon. Certificate, Mr. A. T. Schofield.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 27, Bombay 36, Madras 35, Paris 30, Geneva 23, Brussels 30, Amsterdam 30, Rotterdam 31, The Hague 26, Copenhagen 25, Stockholm 32, Christiania 19, St. Petersburg 40, Berlin 23, Hamburg (State) 29, Dresden 26, Breslau 25, Munich 32, Vienna 31, Prague 41, Buda-Pesth 29, Trieste 38, Rome 28, Turin 26, Venice 35, Lisbon 38, New York 25, Brooklyn 20, Philadelphia 25, Baltimore 23.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

DUNDEE ENGLISH.—The unfortunate misunderstanding between the staff and the managers of the Glasgow Royal Infirmary does not improve as it drags along. We have no hesitation in saying that it has been agitated into a phase and an acrimoniousness which might well have been avoided by mutual conciliation at the commencement, both in the interests

of the staff and the usefulness of the institution. A special committee of the managers recently issued a series of questions on the subject of the administration of anaesthetics to the authorities of the principal hospitals in the Kingdom, and the answers returned are instructive from many points of view, e.g., they are instructive in a direction in which it might be least expected, viz., philologically. Thus, the authority at the Dundee Hospital writes: "I have myself a great respect for chloroform, as an instrument of danger, and with this feeling I invariably, if necessary, inoculate the house surgeon as well!" It seems there are other men in the profession besides the author of "Diphtheria, its Causes and Prevention," &c., who can write startling English.

INFECTIOUS DISEASES IN EDINBURGH.—The Medical Officer of Health (Dr. Littlejohn) on Friday last submitted a report to the Public Health Committee of the Town Council, showing that during the past month there were 173 cases of infectious diseases reported, in terms of section 208 of the Edinburgh Municipal and Police Act, 1879. These comprised 83 cases of scarlet fever, 45 cases of measles, 19 cases of typhoid fever, 16 cases of diphtheria, and 5 cases of typhus fever. Two shillings and sixpence being paid for each case reported, the outlay for the quarter thus represents slightly over £81.

BEQUESTS TO EDINBURGH CHARITIES.—The late Mr. Thos. Cowie has made the following bequests:—To the Royal Infirmary, Edinburgh, £1000; to the Edinburgh Hospital for Sick Children, £250. The above bequests are subject to a life rent.

SEVERE EPIDEMIC OF MEASLES AT KIRKWALL.—The epidemic of measles in the Orkney Islands has spread to an alarming extent, although, fortunately, the fatal cases have not been numerous. In the town of Kirkwall alone over a thousand cases have occurred, and the disease has now attacked almost everyone who has not had it before. In Stromness the school attendance last week went down from three hundred and forty to one hundred and four, and the School Board has resolved to close the public school. In several country districts the epidemic is very severe in older people, and in some instances whole families are attacked at once.

UNIVERSITY OF EDINBURGH.—Dr. J. H. Balfour, late Professor of Botany, has intimated his resignation of the office of Assessor in the University Court for the General Council, on account of continued ill-health.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 31st ult., were at the rate of 36 per 1000 per annum, against 36 in the preceding week, and 25, 26, and 32 in the corresponding periods of 1882, 1881, and 1880.

HEALTH OF EDINBURGH.—The mortality for the week ending with Saturday, the 31st ult., was 89, and the death rate 20, per 1000. Diseases of the chest accounted for 53 deaths, and zymotic causes for 8, of which two were due to fever, and one to measles, the intimations of these diseases for the week being 2 and 16.

SIR ERASMUS WILSON AND JOHN BROWN.—People in Scotland are asking what has gone wrong with the "distinguished" dermatologist, lately President of the Royal College of Surgeons of England. It is all very well, they say, to bring Cleopatra's Needle to London, but there is a mighty difference between this, and founding a Pathological Chair in a University, and asking the public to raise a monument to a Highland ghillie! John Brown, forsooth! "has done honour to Scotland by his integrity and loyalty." Scotchmen are naturally indignant.

THE MEDICAL ACT AND SCOTCH UNIVERSITIES.—We understand that beyond a few concessions to certain Scotch interests, it is not anticipated that the amendments made in the new Medical Acts Amendment Bill will be of an extensive character.

THE CONTAGIOUS DISEASES ACTS AND THE HOUSE OF COMMONS.—A memorial from members of the House of Commons to the Prime Minister is in course of signature, asking him to receive a deputation on the subject of the Contagious Diseases Acts, with especial reference to the motion of Mr. Stansfeld for their abolishment.

Correspondence.

THE LATE DR. G. M. BEARD, OF NEW YORK.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In justice to the memory of the late Dr. George M. Beard will you allow me to correct some, as I believe, wrong statements which were made in the recent obituary notice concerning him in your journal.

The writer referred to the unfortunate attempt of Dr. Beard to exhibit, as a trance-subject, a young man who was really (as claimed) an impostor.

Dr Beard's experiments were perhaps injudiciously conceived, and they certainly had an unfortunate ending. I can assure you, however, that the young man whom he exhibited was a genuine subject, and that Dr. Beard would have been incapable of presenting any other. He was seen many times in this city during the winter of 1879-80, and was tested repeatedly by men quite as sceptical and acute as Dr. Crichton Browne. He was pronounced to be a genuine subject, and it is much more likely that Dr. Browne, who saw him half an hour, was mistaken about him, than the numerous gentlemen in this city who examined him many times. At the time of the London experiments, no doubt, he was frightened and unable to show the purely hypnotic phenomena.

In the subsequent Fall he was in New York, and allowed himself to be again examined by any physicians who doubted the genuineness of his hypnotic conditions. I would insist therefore, that Dr. Beard showed a genuine subject at the International Congress, and believe he would have demonstrated interesting and novel phenomena if he had been treated with a little more courtesy and forbearance. In this connection will you allow me to answer the sneering, and to me most painful and unmanly notice of Dr. Beard, published recently in the *Lancet*. Without detailing at all the actual work of Dr. Beard, the writer of the notice intimates that most of his work was trivial and unimportant. I have not space to enumerate all of Dr. Beard's contributions to medical science. He was a pioneer in electro-therapeutics, and originated (with Dr. Rockwell) general electrization—a measure universally recommended as valuable. Our present knowledge of neurasthenia is mainly due to him, and he made many important additions to its therapeutics. It yet remains to be seen if the now acknowledged phenomena of hypnotism have no practical interest to physicians, and especially to forensic medicine. Two of Dr. Beard's works were translated into German. He was an active promoter of lunacy reform, and of the higher medical education in this country. It seems to me that his record deserves a different encomium than that of the *Lancet*. If its author was too ignorant to do a dead man justice, he might at least have shown him charity.

I am, Sir, very truly yours,

C. L. D.

New York City, March 7th, 1883.

[In our obituary notice of the late Dr. George M. Beard we endeavoured to "be to his virtues very kind, and to his faults a little blind," and we are surprised that any exception should be taken to it. The "trance subject" whom Dr. Beard introduced to the International Medical Congress meeting in London, was proved to be travelling under an assumed name, and declined to allow any inquiries to be made into his antecedents. The series of experiments which he exhibited under the manipulation of Dr. Beard were pro-

nounced by a body of forty or fifty thoroughly competent professional critics who witnessed them, to be merely clumsy tricks, and attempts at deception, and the estimate formed by the medical profession in America of the prominent part taken by Dr. Crichton Browne in letting in the light of scientific truth on the dark corners of sham hypnotism, was evidenced by his election shortly afterwards to the Fellowship of the Academy of Medicine of New York.—Ed.]

Literature.

CROOM ON MINOR GYNÆCOLOGICAL OPERATIONS. (a)

DR. CROOM tells us in the preface to the first edition of this little manual that "if the following pages succeed in giving to the students attending my classes for diseases of women, a short and practical account of the more common gynæcological operations and appliances, they will attain the object for which they were written." The object aimed at was a modest one, and that the author's efforts in the attainment of it were successful, and appreciated by the classes for whom the book was written, is rendered evident by the need for a second edition. For a large class of practitioners, as well as for the members of the author's classes, a handy manual of instructions, such as the one before us, in which the various plans of operative treatment are methodically laid down, cannot fail to be useful.

The chapters on the physical examination of women are very good, and contain not only almost all that a student needs on this subject, but many practical hints likely to be of service to those of riper years. The bi-manual method of examination is as much insisted on as it is by Scanzoni. A little oversight that occurs on page thirty-eight may be mentioned. The author says that "there are three methods of examining the female bladder," after which he immediately proceeds to give four.

If we might make a suggestion it would be that perhaps the work would have been rendered more useful if a choice of methods of performing these minor operations had been offered to the student. As it is, that method which has appeared to the author to be the best is given, whilst others, perhaps equally good, are often conspicuous by their absence. Thus in the instructions in the method of using the uterine sound, but one method is described, viz., that in which the index and middle fingers of the right hand are to be passed into the vagina and employed as guides, whilst the left hand grasps the instrument and controls its movements. The method made use of by a great number of gynecologists, and for which it is claimed that greater delicacy in the manipulation of the sound is obtained, viz., that in which the index finger of the left hand is employed as the director, whilst the instrument is worked by the right hand, is altogether omitted. This tendency to omit methods of procedure not actually made use of by the author himself pervades the whole work and gives to it a sort of narrowness that cannot fail to be felt by the careful reader. The omissions are no doubt intentional on the part of the author, as tending to keep the work within prescribed limits, but notwithstanding this, we venture to express the opinion, that the work might have been made more perfect by describing the various modes of doing certain things, that are adopted by various well known gynecologists, and that the work might still have been kept within the prescribed limits by omitting altogether the chapters devoted to operations confessedly not minor. Surely Dr. Croom would not wish his pupils as soon as they have mastered the technical details of his book to proceed to the enucleation of uterine fibroids, or to attempt the reduction of long-standing inversion of the uterus. Notwithstanding this, however, which we take to be a blemish, and the only blemish, we think the book will serve a useful purpose, and we wish it success.

The work is adorned by twelve plates, one of which is brilliantly coloured, which are good, and forty woodcuts, some of which are very diagrammatic. It is handy in size, well got up, and contains a good index, a good feature in any book likely to be of use.

(a) "Manual of the Minor Gynecological Operations and Appliances." By J. Halliday Croom, M.D., F.R.C.P.E., F.R.C.S.E. Second edition, revised and enlarged. Edinburgh: E. and S. Livingstone. London: Baillière, Tindall, and Cox. 1883.

Notices to Correspondents.

"A CASE FOR THE BENEVOLENT."

We have received 5s. from Dr. Kelly, Rotherhithe, London, and £1 from Dr. J. E. Kenny, 15 Rutland Square, Dublin, towards this deserving case.

THE TREATMENT OF COMEDONES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Would you have the kindness to answer me in your next issue of the *Medical Press and Circular* if you know of any treatment that would be successful for comedones, i.e., acne punctata. I have tried several remedies, but am sorry to say that they have all failed—both hydrarg. bichlor., emula. amygdal., and sulph. precip. c. camph. I would be much obliged if you would kindly give me the information I require, and oblige,

Yours truly,

AN OLD READER.

[We would recommend Turkish baths, attention to the general health and diet, and a course of iron and nux vomica. Particular care must be bestowed on regularity of the bowels; and, should they be costive, a wineglassful of Hunyadi János water every morning an hour before breakfast will be found effective. The best local treatment is removal of the comedones by Piffard's extractor—a scientific imitation of the old "watch-key cure." This instrument is depicted, and its use described, in page 158 of Piffard's "Materia Medica and Therapeutics of the Skin" (London, 1881). Piffard describes its use as rather painful; but it does not appear to have occurred to him to use it immediately after the Turkish bath, when it is easy and absolutely painless.—Ed.]

DR. P. J. is thanked for his notes on "Rhamnus Purshiana." Proof shall be sent as requested.

DR. J. W. B. is thanked for the information; he will see the subject has been referred to in another column.

MR. H. O. THOMAS ON "THE ACTION OF SEDATIVES AND STIMULANTS ON NEEVES."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In reply to the letter of "A. W. W.," in your last issue, I have to state that over twenty years ago I came to the conclusion that belladonna was a stimulant, and my clinical experience ever since has been to confirm me in that view. I am just now bringing out a small volume on "Intestinal Obstruction," in which are to appear some of the cases which support my view, and other interesting information on the subject of the action of drugs.

Yours, &c.,

H. O. THOMAS.

Liverpool, April 9th.

DR. P. J. MERCIER (Paris).—Sorry we cannot exchange; our list is already too full.

DR. E. S. T. will receive a private note.

AUTHOR WANTED.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—A few days ago I got here a letter from the Secretary of the "Instituto Medico Valenciano" (Spain), stating that he had received an essay with the title "Are Diseases of the Heart, Phthisis, and Insanity more frequent at present?" &c., and that an honour had been awarded this essay, but the author had omitted to enclose his name and address. He therefore asked me to make this public. I hope you will kindly insert this in your next issue, and if any author who has competed will forward me his motto I will advise him (if he be the successful candidate) to whom to apply for the prize.

Yours truly,

P. M. BRAIDWOOD.

17 Rodney Street, Liverpool,
April 4th, 1883.

[Since the above was put in type, we have ascertained that the author of the successful essay is our esteemed correspondent, Dr. T. M. Dolan, of Halifax, Yorks.—ED.]

THE SINGLE QUALIFICATION AND THE NEW MEDICAL ACT.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Surely the framers of this measure have failed to appreciate (as only those on whom it is brought to bear can appreciate) the great injury that will be done to medical men already in practice with a single qualification.

There are hundreds of practitioners holding public appointments, or conducting large practices, who have only a single medical or surgical diploma. What is to become of these? They are too old to recommence reading for the new Licence of the Medical Council, and cannot be expected to give up their appointments and practices. Should the present Bill become law, it will be absolutely necessary that every "Registered Practitioner" (at the time of the passing of the Act) should have the Licence of the Medical Council conferred *ad eundem*. There is at present no provision for this; let us hope that such an obvious oversight will be remedied.

Yours truly,

A PRACTITIONER WITH A SINGLE DIPLOMA.

FIBROID.—They are out of print. Their author has under consideration the republication of the series in an extended and revised form.

MEETINGS OF THE SOCIETIES.

WEDNESDAY, APRIL 11TH.

HURTERIAN SOCIETY.—At 7.30 p.m., Council. 8.0 p.m., the President Mr. Bivington, On a Case of Removal of Loose Cartilage from Knee-joint.—Dr. J. Herbert Stowers, On Observations upon the Nature and Treatment of Infantile Eczema.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Mr. M. Morris and Mr. G. C. Henderson, On the Life History of the Ringworm Fungus (*Trichophyton tonsurans*).—Mr. C. G. Matthews, Notes on the Red Mould of Barley.

THURSDAY, APRIL 12TH.

ACADEMY OF MEDICINE IN IRELAND (Sub-Section of Public Health).—At 8.30 p.m., Papers: By the Secretary, Communication from Dr. B. Angus Smith, F.R.S.—Dr. C. A. Cameron, On Consanguineous Marriages in relation to Deaf-mutism; Antiseptic Experiments in a Mortuary Vault.—Dr. W. McDowall A. Wright, A Suggestion for the Disposal of Sewage in Irish Country Villages.—For Exhibition: (1) Models and Specimens Illustrative of Sanitary Improvements, and Specimens of Insanitary Appliances; (2) Disinfecting Appliances; (3) Disinfecting Hot-Air Chambers, explained by Mr. W. R. Maguire.

FRIDAY, APRIL 13TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. Sémon, On Removal by Internal operation of a Pin from the Larynx, in which it had been impacted for thirteen months, and had caused Anchylosis of the Left Crico-Arytenoid Articulation.—Dr. Whiphram, On Two Cases of Enteric Fever, accompanied by an Erythematous Eruption, resembling that of Scarlatina.—Mr. B. Roth, On a Case of Lateral Curvature of the Spine, illustrating its treatment without the use of mechanical supports.—Mr. Page, On a Case of Tabetic Arthropathy in which the Tarsal Bones of both Feet were Involved.—Mr. Barker will exhibit a Case of Subperiosteal Amputation at the Hip-joint.

SATURDAY, APRIL 14TH.

ROYAL INSTITUTION.—At 3 p.m., Mr. A. Gelkie, On Geographical Evolution.

Vacancies.

Leigh Local Board.—Medical Officer. Salary, £50. Applications to be sent to the Clerk on or before April 23rd.

Liverpool Royal Infirmary.—Resident Medical Officer. Salary, £100, with board and lodging. Applications to be addressed to the Chairman of the Committee on or before April 25th.

Lincoln County Hospital.—House Surgeon. Salary, £100, with board and lodging. Applications to be sent to the Secretary on or before April 23rd.

Rathfrum Union.—Workhouse Medical Officer. Salary, £100, and £15 as Sanitary Officer. Election, April 20th.

St. George-in-the-East Parish.—Assistant Medical Officer. Salary, £120, with residence, &c. Applications to the Clerk by April 15th.

Whitehaven and West Cumberland Infirmary and Fever Hospital.—House Surgeon. Salary, £150, with residence. Applications to be sent to the Secretary before May 1st.

Appointments.

ANDREWS, A. G., M.B.C.S., Resident Accoucheur to the London Hospital.

ASLETT, G. S., M.B.C.S., Resident Medical Officer to the Newark-upon-Trent Hospital and Dispensary.

HENSON, S. B., M.B.C.S., L.M., Medical Officer to the Hull Workhouse.

HITCHCOCK, C. K., M.D., M.A. Cantab., Medical Superintendent to the Lunatic Hospital, Bootham, York.

OAKLEY, A. R. H., L.R.C.P. Ed., House-Surgeon and Secretary to the General Infirmary, Hertford.

O'CONNOR, F., L.K.Q.C.P., L.R.C.S.I., Medical Officer to the Second District of the North Wiltford Union.

ROGERS, E. C., M.B.C.S., Medical Superintendent to the County Lunatic Asylum, Fulbourn, Cambs.

SCOTT, E. S., M.B., C.M. Ed., Medical Officer to the Shrewsbury Dispensary.

SPENCER, H. B., M.D., Surgeon to Her Majesty's Prison at Oxford.

WILLIAMS, E. E., M.B.C.S., L.R.C.P. Lond., Junior House-Surgeon to the Stanley Hospital, Liverpool.

Marriages.

ESLER—RENTOUL.—March 22nd, at Whitehouse, Belfast, Robt Esler, M.D., M.Ch., Belfast, to Erminnda, daughter of the late Rev. Alet Rentoul, D.D., M.D., of Manorcunningham.

JOHNSTONE—BROOKE.—April 5th, at All Saints', Langport, Dr. James P. Johnstone, second son of the late Dr. J. M. Johnstone, Demerara and Bath, to Evelynne Jane Eunice, Eldest daughter of Dr. T. G. Brooke, Langport.

Deaths.

AMBROSE.—March 26th, at Howth, co. Dublin, Thomas Ambrose, M.B.C.S. Eng., aged 78 years.

BANNISTER.—March 27th, suddenly at his residence, Dudley House, Deal, Kent, Henry Powell Bannister, M.B.C.S., aged 57.

DAVIDSON.—March 31st, at Cheltenham, A. Davidson, M.D., Inspector-General of Hospitals, aged 85.

FULLER.—March 30th, at Brighton, Thomas Warburton Fuller, M.B., eldest son of Thos. Fuller, M.D., of shoreham, aged 27.

HAINWORTH.—March 29th, at Queen's Road, Edmonton, John Hainworth, F.R.C.S. Eng., aged 79.

HEWETSON.—April 3rd, at Clonmel, D. Millett Hewetson, L.A.H., last surviving son of James Hewetson, M.D., of Thurles.

MABBY.—April 1st, at Wolverhampton, Herbert Lynsey Mabby, Surgeon, of Brewood, Staffordshire, aged 23.

MOUSTRAY.—March 28th, at Ashburnham, Shackleton Green, Dalston, Charles Drummond Moustray, M.B.T.C.D., aged 23.

NEAME.—April 3rd, at his residence, Birchington-on-Sea, Thomas Albert Neame, M.B.C.S., aged 46.

PEYTON.—At Boscommon, H. B. Peyton, L.R.C.S.I., L.M.K.Q.C.P., for thirty-five years Surgeon to the Boscommon County Infirmary.

REID.—March 26th, suddenly, at Eilon, James Reid, M.D.

SWAIN.—March 24th, at Fenice Cottage, Stoke, Devonport, Paul Wm Swain, F.R.C.S., J.F., aged 74.

ON

STERILITY IN WOMAN.

Delivered in the Royal College of Physicians, London,
February, 1883.

By J. MATTHEWS DUNCAN, M.D., F.R.C.P.L.,
Physician-Accoucheur and Lecturer on Midwifery at
St. Bartholomew's Hospital, &c.

LECTURE III.—PART I.

ITS PREVENTION AND CURE.

MR. PRESIDENT, VICE-PRESIDENT, AND GENTLEMEN.—As in past ages, so also in modern, sterility has been an object of great interest, of study, and of experiment. The acquisition of wealth has at all times stimulated the agriculturist, the gardener, and the breeder; and the desire of offspring has no less stimulated men and women. At no time has the subject had more importance than at present, for the growth of science and the love of daring speculation bring now on the field a class of men of trained intellect, who invade it, not to make money or secure offspring, but in search of knowledge. It is to such men that Nature opens her secrets, and the divulging of truth through them is the just pride of philosophy.

A true theory of sterility, even though it be lamentably incomplete, is of very great importance in medical practice. Thousands of women are seeking what they call cure, and their advisers should surely take care to know what they can offer in return for the confidence placed in them. According as medical men have their course illuminated by knowledge, so will they be wise in advising; and if increase of knowledge, acting directly or by dispelling illusions, destroys faith in remedies, it may yet, in this negative way, add to the usefulness of the adviser. It has been said by Brodie of John Hunter that by teaching us when we are not to interfere with the ordinary course of events he has contributed more towards the advancement of the healing art than all the inventors of remedies who had gone before him.

The course and the details of the argument in these lectures point to a law or laws of sterility not yet clearly formulated; and it is to be expected that progress will be obtained from inquiries such as have been here described, as well as from investigations of the intimate state of the reproductive organs, including those parts of the nervous system which govern them or are governed by them.

Deficient reproductive energy or want of sexual vigour is a theory too vague to be satisfactory. It is only a general idea which loosely binds together, meantime at least, the items of knowledge we have acquired as to sterility. Of course it is a general idea to whose entertainment no known fact is hostile. But it is flimsy, like a ghost, and a fact might find it difficult to prove its steel; for, like a ghost, it might be cut by a sword without being destroyed or even damaged in the eyes of those who see it. Deficient reproductive energy is held to be proved by all the conditions which produce or which attend sterility in plants, animals, and man. In woman it is shown by absolute sterility, by relative sterility, by excessive production, and by imperfect production, which may be abortion, or miscarriage, or morbid pregnancy, or children diseased or difficult to rear, or destined to peculiar diseases during extra-uterine life. Deficient reproductive energy cannot be regarded as a substantive disease with specific characters, course, and remedies. It is a constitutional condition, which, according to its cause, may affect a population or affect certain classes. Cold or heat may render a whole population sterile. Under-feeding or over-feeding, or premature or post-mature marriage, may cause sterility in certain classes within a population. Sterility, the result of deficient reproductive energy, is an imperfection which does not show itself by measurable, tangible qualities such as a dwarf exhibits, but by absence of function, or a stunted or otherwise imperfect performance of function.

The consideration of the great causes of sterility, exhibited as they are in their results in populations and in classes of women, makes it almost certain that local causes, whether acting as impediments to conception or as unfavourable to pregnancy and to intra-uterine life, have very little scope for operation. These local causes have a clinical interest as affecting individuals; for they have not been supposed, far less shown, to have any connection, or even

accidental association, with the great causes whose scope is wide and certain. In the production of cancer of the womb there may be great operating causes, such as age and multiparity, and there may be minor local causes, such as the so-called ulceration of the cervix uteri and its injudicious treatment; and these minor causes, although doing little harm to a population or a class of women, may be of the highest practical importance to individuals.

In women, the chief and best demonstrated sources of, or attendants on, sterility are juvenility or prematurity, elderliness or post-maturity, dysmenorrhœa, and disorder of sexual appetite and pleasure. Of these the influence of age has been most fully shown, and it is that which is most under control with a view to prevention.

As in cases of constitutional diseases or of epidemic fevers, so here, the good done by prevention immeasurably exceeds, or may immeasurably exceed, any possible good by cure; and this, whether the good done is to a population or class or to an individual. The superiority of prevention is partly because the good is to a population or class, not to mere individuals. Prevention is to be, in part, effected by avoidance of unions of immature women or of elderly women: in other words, by securing that women are married at the age of nubility, or best age of marriage, with a view to fertility and the rearing of healthy children, and the safety of the mothers, and this age is fairly well ascertained to be, for a population or mass of women, not under twenty and not above twenty-five.

In the breeding of domestic animals and of animals in confinement, man can interfere easily and without restraint, except from his own interests, but it is otherwise in woman. She enjoys liberty within wide limits, and she is more or less subject to the restraint of social, moral, and religious law or custom. These restraints diminish the power of the medical adviser to guide; and, in general, he can do most good by diffusing knowledge as to the prognostics from marriage entered into under various conditions.

At present the law of England legitimises marriage at a very early, a too early, age; and it, wisely no doubt, does not interfere with late marriages. "Without the sanction," says Major Graham, "of the laws of physiology, or of common sense, a girl may—but in the present day rarely does—marry at the age of twelve, a boy at the age of fourteen, under the existing laws of England; but the consent of parents and guardians is required in certain cases where either party has not attained the age of twenty-one; and the proportional number of either boys or girls who marry under the age of twenty is happily small." . . . "The age," he adds, "of marriage cannot be directly fixed by laws; but legislation, by prescribing the minimum age of marriage, and the age of majority, does exercise a considerable influence on good numbers of the people directly, and on all indirectly. It becomes the custom or the fashion not to marry below the age of majority. Thus in England about 9,000 young persons of the age of twenty and under twenty-one married in the year 1851; while about 139,000 married in the four years after they were of a *se*, as it is called, or in the years of age, twenty-one to twenty-five. The age of majority is twenty-five years in France; and the age of twenty-five divided the minors from the majors in Roman law. The advanced age of majority, or of what becomes practically the lowest age of marriage, retards marriage indefinitely in many cases, and will probably be found, on investigation, to account, at least partially, for the comparatively small number of children to a marriage in France. By raising or depressing the age of majority, the Legislature then has the power to exercise considerable control over the population." These remarks of Major Graham are valuable in themselves, and indicate the view taken by a politician. The law of majority has no doubt great influence, and by it the State can modify the age at marriage to some extent; but the laws of love, of self-interest, and of social convenience are much more powerful.

The sterility of near relations, of interbreeding, or of breeding in and in, as it is often called, is generally recognised, though far from well proved in man, and forms what seems a contradiction in terms, an inherited sterility. It is believed to be shown not only by absolute sterility and its accompaniments, but also by the production of idiots and ill-formed children. Restraint by knowledge of these risks of intermarriage is no doubt a powerful preventive of sterility, but not so potent as it ought to be.

There is, as already pointed out, a sterility dependent on

some inscrutable incompatibility of the parties, as in Augustus and Livia, Napoleon and Josephine. Cases like the following are not very rare, and I have actually observed them. A man marries successively three childless widows and has children by each of them. A woman is married successively, and within childbearing limits, to three men, and has children by only one of them. Such cases, if very rare, might carry little weight, but they are so common as to have occurred within the knowledge of most observant people. Sterility of this kind we cannot foresee and prevent; and religion, morals, and law continue to interdict the cure that might result from a change of husband. Unfortunately, however, among large classes—chiefly, I am told, in Wales and some parts of Scotland—custom permits, and local morals do not interdict a practice which produces many illustrations of this mutual incompatibility. The practice is called *bundling*, or keeping company, and consists in parents permitting daughters to cohabit with an eligible man on the understanding that, if pregnancy ensues, the legal marriage tie is made. A woman proving sterile may be deserted by her follower, and gets another with whom the result is different.

In ancient times much was known and taught regarding the avoidance of sterility, and most of it was in accord with what is still taught, but little was done with a view to the cure. The physiology of reproduction was little advanced, and its primary or elementary conditions quite unknown. When certain winds were believed to cause sterility, and fecundation was supposed to be effected by an aura seminalis, we could not look for rationality in practice. Accordingly, such cures of sterility as were then practised appear to us ridiculous or fantastic.

In modern times the physiology of reproduction is comparatively far advanced, and the necessity of the physical conjunction of the male and female elements is especially recognised. But it may be doubted whether the cures of sterility are much more rational than those of the ancients, for the laws of sterility have been investigated with no great amount of success; and especially do we remain uncertain as to the physiology of the conveyance of the spermatozoa to the Fallopian tubes.

During the last thirty years gynecology has made great and rapid strides of substantial progress, and naturally sterility, as part of it, has swollen in bulk; but the growth of it has not been satisfactory, for it has not a sure foundation. While our general knowledge of sterility in woman has made little advance, and especially that part of it which might be turned to practical account, the curing of sterility has reached great dimensions. As in other departments of therapeutics, there has been a great failure of logic; the *post hoc* and the *propter hoc* have been confused—a coincidence has been regarded as a consequence. The credulity of patients and of doctors has been a basis for useless and often injurious practice.

It is scarcely an exaggeration to say that, in recent practical works on sterility, there is exhibited entire ignorance or entire neglect of the laws of fertility. Every woman from fifteen to forty-five is regarded as likely to breed. If she is sterile, a cure is at once set agoing, and if a child is not born, the failure is not debited to the nature of the case, but to the want of ingenuity in the doctor. A reputation for curing sterility is spoken of as if it were founded on substantial claims. The prevalent methods of curing sterility are founded on an implied theory that it in most cases arises from impediments in the way of the spermatozoa reaching the ovum. Without sufficient evidence strictures are assumed to exist, versions and flexions of the womb are held so to distort the interior passage as to prevent progress of the spermatozoa, cervical catarrh is believed to stop them by mechanical obstruction, or by chemically poisoning them; and for these real or imagined evils sterile women are made the subject of treatment. It is the theory of mechanical obstruction that by its simplicity and directness has possessed the profession and the public, and accordingly many operations and modifications of operations, and very many instruments have been devised to do away with the obstruction. The theory has had real rational support, in the fact that dysmenorrhœa of a spasmodic kind does, as already shown, frequently accompany the sterility, and in the supposition that the same obstruction which causes sterility by impeding the entrance of semen causes also dysmenorrhœa by impeding the exit of menstrual blood, or *vice versa*. It has had still more satisfactory support in the observation

that the cure of the dysmenorrhœa does occasionally bring with it cure of the sterility.

The very zeal with which the mechanical theory of sterility has been fostered, and its treatment in many ways pursued, has led to its present decadence, and there is now increased attention paid to other departments of fertility than conception. Especially and justly, the difficulties of naturally starting and healthily continuing pregnancy are brought prominently into view. The mechanical obstruction theory has begun to shrivel, because of the impression produced by the enormous, though inexact, proportion of the failures of the attempts to cure founded on it. Even the ignorant sterile women could see that, if the theory of causation were true, there was an easy and plain theory of cure, and they could also see that the failure of the so-called cure was prejudicial to, if not destructive of, the theory. The importance of the difficulties of pregnancy now brought into prominence will, on account of its great reconditeness, be received with no enthusiasm, such as welcomed the obstruction theory, and the physicians who entertain it can offer no such brilliant prospects of cure to their confiding patients. It is, however, a decided step of progress in a subject of great practical importance.

It is in Germany that this department of sterility has been chiefly studied, and Grünewaldt, of St. Petersburg, is its best exponent. Recognising the importance of this work, I take the liberty of using it to show the great incompleteness of even the most advanced accounts of the subject. For Grünewaldt, sterility is truly never a disease, but a symptom of a disease. Nature has, he says, set no limits to female breeding other than the natural changes in the sexual organs that are observed in the senile state. Sterility is one of the most frequently occurring disturbances of function caused by diseases of the female sexual organs. In these views, and in his whole work, it is implied that sterility depends on disease of the sexual organs, including chiefly endometritis, mesometritis, perimetritis, and parametritis. The difficulties of conception, he says, have only a slight importance compared with the disorders of the more important vital processes of pregnancy, and these disorders affect chiefly the tissues of the uterus.

It would involve a useless recapitulation of the substance of these lectures were I to set about showing how partial and imperfect is that theory of sterility which makes it depend on local disorder or disease, whether the disease impedes conception or interferes with the progress of pregnancy. Taken together, the obstruction theory and the theory of Grünewaldt do but cover a small part of sterility, which may be described as the part affecting scattered and sparse individuals, and giving thus its importance to these individuals, and to their advisers.

The obstruction theory and the theory of Grünewaldt make no room for that kind of prevention which we have described as of paramount importance. On the other hand, they open up great, indeed almost unlimited, fields for the activity of curers. But the failures of curers is so notorious, and the curing of sterility has so bad an odour in the nostrils of many, probably of the majority, of the best in the profession, that it is worth while to ask the question, Is sterility curable?

Before this question there comes another which is of great importance. Should sterility be cured, as it is called? That, in the interest of the community, it should be prevented I have no doubt; but, in this department of the subject, statesmen and economists have taken much interest, and I shall not meddle in it. I am of opinion also that it should, if possible, be cured. Yet a good argument may be made out for not curing it, in many cases at least. For the laws of sterility show that if it is, what is called, cured, there is a risk of some of its alternatives or attendants—morbid pregnancy, abortion, miscarriage, weakly children, excessive family, death of the mother, and others. But the practitioner hopes, by appropriate cures, to conduct his patient and her offspring in safety through these perils; and we do not, meantime, feel disposed to cavil with this perhaps over-estimated view of his rational expectations.

It will be admitted that reputation, even with well-informed medical men, is not sufficient to prove the reality of a so-called cure, and we are constantly meeting with instances of exaggerated credulity in reported cures of young women married between twenty and twenty-five, and who had not

lived three years in the married state, for it is common for such ardent young women to thus prematurely regard themselves as doomed to persistent sterility, and seek advice with a view to averting their dreadful fate. But there can, I think, be no doubt that sterility is often cured, and such cases as the following do all but absolutely prove that cure is possible, and the sufficiency of the proof will not be controverted by anyone if it is added that such cases, though rare, are sufficiently numerous to prevent by their number, apart from their other circumstances, the confusion of a coincidence with a consequence.

A. B—, married at twenty years of age, menstruated regularly since thirteen, has had dysmenorrhœa most of her life, but not very severe, has never been pregnant. Has had no uterine treatment till now, when the cervix was canalised by bougies in the usual way twenty-two years after marriage. No known change was made in her conjugal or other habits. She became pregnant at once after the treatment, and had a living healthy child at forty-two years of age. Now, five years after the birth, pregnancy has not recurred.

C. D—, married at nineteen years of age, began to menstruate at thirteen, and is regular, with pain for a short time on the first day. After fifteen years of married life has had no pregnancy. Has had much uterine treatment. Cervix canalised by bougies, and for the first time, according to her. No change made in conjugal or other habits. On resumption of cohabitation, two months after treatment, became pregnant, and had a healthy child at thirty-five years of age. Since this birth three years have elapsed, and she has been twice pregnant.

It is, however, desirable to go further than merely prove that cure is possible, that a cure has been effected; and I believe the most important means of curing sterility or relative sterility is improvement of the general health. In the case of plants, the value of digging about and dunging is well known, and so is the value of proper exposure to the sun, and so is the value and, indeed, the necessity of good air, not the air of large cities; and the use of these, when previously withheld, is certainly curative of sterility in many kinds. The cure is sometimes, as in apple or pear trees, removed from the shady side of a wall to a better exposure, accompanied by other changes in leafage and in growth of wood, which make better general health evident to the eye. But the cure may have no accompaniment of other signs of better general health, for some London trees which are sterile have a fine outward show of healthy vigour, and it can scarcely be doubted that return to a purer atmosphere would restore their fertility, though it could do little to improve their appearance. In the case of animals, a similar influence of general health may be noted. The starving of fowls diminishes or even arrests their fertility. We cannot doubt that the agouti, released from confinement and restored to its natural habitat, would produce healthy offspring instead of dead and ill-formed; and that, similarly treated, the lioness would have cubs without cleft-palate.

In the case of woman, the restoration to, or improvement of, general health involves such a variety of considerations as renders it very difficult of treatment, and the whole matter comes as much under the care of the general physician as of the gynecologist. But it may be mentioned that special means have been recommended, and are much used, such as the waters and baths of Germany. These are of different kinds: and the Schwalbach, Sp, Franzensbad, Ems, and Marienbad have great reputation. That they are often of some kind of service I have no doubt, just as I dare say that horse-riding, said to be recommended by Boerhaave against abortion, may also be sometimes valuable as a remedy of that tendency.

It may well be objected that general health is too vague a term, and that it would be better to profess ignorance than to ascribe to it such important and definite a result as sterility, and it will be justly asserted that the great mass of sterile women have the appearance of good health. The difficulty of the subject is well expressed by Darwin in a passage I have quoted treating of the causes of sterility in animals. After all, I think it best, in the present imperfect state of our knowledge, to group a large number of injurious ill-defined influences under the head of general health, and to consider its improvement a means of cure. Although an animal sterile under confinement appears healthy, one cannot

positively object to the statement that sterility is evidence that it is actually unhealthy, and the cure by restoration of freedom seems to confirm the view. Whatever may be the objections to the term "general health," everyone will recognise the importance of investigating the subject with a view to increasing our power over it, for it carries with it a strong influence not only towards the cure of simple sterility, but also towards the safety of the mother, the avoidance of morbid pregnancy, of miscarriage, of dead, ill-formed, and unhealthy children, and of excessive families.

Over-feeding and the production of fat are often spoken of as if they were identical; but this is plainly not the case, for many excessive feeders are not fat. What is the influence on sterility of over-feeding or feeding by particular foods without fattening, I do not know; but there are analogies which dispose the mind to suspect that influence may be thus exerted. Plants are habitually spoken of by gardeners as overfed by rich soils and manures, but they do not get fat. Mr. Thomson, recently showing me his tomato plants, pointed out some, set among strong manure, growing luxuriantly in wood and leaves, but producing little fruit; others, which had been similarly placed, he had restored to due fruit-bearing, with diminished production of branches and leaves, by diminishing the contact of their pots with the rich manure. The growth of stems and leaves some may regard as the equivalent of fat in animals, but in that case stoppage of growth would be equivalent to resorption of fat, which would be driving analogy too far.

Although the injurious influence of fatness in women on fertility is universally admitted, it has not been altogether proved. But universal consent is strong evidence, and it is corroborated by all we know of the power of this same condition in the lower animals. Generally, young women before commencing to breed are fat or at least plump. When they bear children they lose in weight by diminution of fat; again, as they cease to bear children, to resume the fat condition, the fat being now, however, differently disposed of in the body. The fat of the immature and of the post-mature is, within moderate limits, an indication of health. The fat of sterility is not an indication of health, but is, so far as I know, itself healthy, and indicates no active or positive disease. To obesity I only make allusion. I have known grossly fat women bear children; but facts about obesity are too few to justify its separation from the common exaggerated fatness of sterility here referred to.

Spencer makes a distinction between normal plethora and abnormal plethora as indicated by fat, and connects sterility only with the latter. I quote his ingenious remarks not so much for the sake of giving his description of a distinction, the force of which I cannot see, as for the sake of stating his general argument regarding overfeeding or plethora as indicated by fatness. Medicine recognises no normal plethora. For physicians plethora is always an abnormal condition whether accompanied by much deposit of fat or not. "Many facts," says Spencer, "may be brought to prove that fatness is not accompanied by fertility, but by barrenness; and the inference drawn is that high feeding is unfavourable to genesis. . . . There is a distinction between what may be called normal plethora and an abnormal plethora, liable to be confounded with it. The one is a mark of constitutional wealth; and this is the plethora which we have found to be associated with unusual fecundity. Abnormal plethora, which, as truly alleged, is accompanied by infecundity, is a superfluity of force evolving materials joined with either a positive or a relative deficiency of tissue-forming materials: the increased bulk indicating this state being really the bulk of so much inert or dead matter. Note, first, a few of the facts which show us that obesity implies physiological impoverishment. . . . Neither in brutes nor men does it ordinarily occur either in youth or in that early maturity during which the vigour is the greatest and the digestion the best; it does not habitually accompany the highest power of taking up nutritive materials. When fatness arises in the prime of life, whether from peculiarity of food or other circumstances, it is not the sign of an increased total vitality. . . . Of like meaning is the fact that women who have had several children, and animals after they have gone on bearing young for some time, frequently become fat and lose their fecundity as they do this. In such cases, the fatness is not to be taken as the cause of the infecundity; but the constitutional exhaustion which the previous production of offspring has left

shows itself at once in the failing fecundity and the commencing fatness."

The fatness of sterility is not apparently a matter of high or low general health, and seems to be of a different origin from that fatness which comes on men and women at the great climacteric, and on the latter whether they have borne children or not. Whatever may be its natural history, it is known to be in some degree under the control of the physician. Not by medicine, but by diet and exercise, he can restrain its production or cause its removal. For success in removing fat the co-operation of the patient is necessary, for on her part there is required change of habits and restraint of appetite. Little can be said regarding the cure of sterility by reduction of fat, but experience has furnished no reason to doubt the favourable influence generally expected from it.

THE CAUSES, SYMPTOMS, AND TREATMENT OF PHIMOSIS AND PARAPHIMOSIS. (a)

By LAMBERT H. ORMSBY, F.R.C.S.,
Surgeon to the Meath Hospital and Co Dublin Infirmary; Lecturer
on Clinical and Operative Surgery.

(Continued from page 315.)

5. Complete Circumcision.

This procedure in very aggravated cases of phimosis produces the best results. There are a great many ways of accomplishing it and few operators adopt an exactly similar mode of procedure (Fig 2). Circumcision by means of

FIG. 2.

Prepuce slit by single incision.

Ricord's forceps is performed, thus the prepuce is grasped and drawn forwards and placed between the blades of the forceps which is held firmly by an assistant downwards and forwards, when the prepuce is drawn forwards it should not be allowed to slip back. A needle armed with a double ligature is then passed through the slits in the forceps from side to side. They ought to be long enough so as to allow them to be cut in two. This needle should be passed through twice and care should be also taken to see that the ligatures are passed in the centre of the slit as well as through the centre of the prepuce, or the needle with ligature will pass between the skin and mucous membrane. When the ligatures have been introduced the assistant should be directed to grasp the prepuce firmly between the blades of the forceps, which should be held obliquely downwards and forwards, the prepuce in front should then be removed with one sweep of the knife. The forceps are then removed and with a hook or aneurism needle the ligatures should then be looked for and hooked out and

(a) Being a clinical lecture delivered in the Meath Hospital and Co. Dublin Infirmary

each ligature cut in the centre and tied to its other end at the side it belongs. In this way each separate ligature is tied all round, and by this means the external skin and mucous membrane are stitched evenly together (Fig. 3). It

FIG. 3.

Showing how Skin and Mucous Membrane are stitched together.

is generally better to nick in two or three places the mucous membrane and skin that is left behind to prevent contraction after the part heals. Such is the manner of performing the operation after Ricord's method, and with his forceps (Fig. 4). However, although being a very admirable method

FIG. 4.

Circumcision by Ricord's operation.

in theory it sometimes disappoints in the practice. In the first instance when the ligatures are not passed exactly in the centre of the slit they pass between the mucous membrane and the skin, and after the prepuce is divided and when the ligatures are looked for they are found in a situation perfectly useless, and have consequently to be

introduced through the skin and mucous membrane *de novo* giving rise to great pain. Again, a small vessel may be cut and, as a matter of necessity, it must be transfixed with the needle and ligature so as to arrest it. In this operation, therefore, the most painful part of it, and the part that takes the most time, is the passing of the needles armed with the ligatures so as to bring evenly together all round the skin and mucous membrane, after which it should be dressed with narrow strips of wet lint. Some surgeons in the first instance draw the prepuce forward and transfix it with a long pin or needle and cut the part off with one sweep of the knife in front, and then slit up for a short distance the divided portion with a pair of scissors so as to prevent subsequent contraction. From the foregoing it can be easily seen that no two surgeons operate alike, and ordinary dressing or long bladed forceps has been used instead of Ricord's. Complete circumcision is sometimes recommended and performed for the removal of a chancre on the prepuce, and it does not follow at all as has been said that the chancre will attack the part incised.

Acquired or Inflammatory Phimosis.

This condition may frequently be met with in those who are not particular about their persons and who allow the pent up secretion to become indurated between the glans and the foreskin, the prepuce from irritation becomes inflamed and the edges swollen and fissured; or again, it is sometimes a common condition in gonorrhœa, chancre, or herpes preputialis. If allowed to continue unchecked the inflamed prepuce becomes distended with serum and assumes a considerable size. Repeated attacks of this kind causes it to be permanently indurated and elongated, and its orifice contracted. Small multiple chancres around the orifice of the prepuce on healing nearly always become hard cicatrices behind, contracting the parts so as to produce acquired phimosis. Besides the inconvenience of this condition locally inasmuch as in the case of congenital phimosis, it acts as a great obstacle to complete urination, sexual intercourse, and proper ablutions of the part. We find it also producing other morbid conditions by reflex action. L'Allemand enumerates it among the causes of spermatorrhœa, irritation of urethra and bladder, finally cystitis, curvature of the spine, reflex paralysis, prolapsus ani.

Treatment.—At the very commencement when the condition is first observed the prepuce and penis will be very red, swollen, and painful, and the preputial orifice very much contracted. It is not good practice to think of an operation, either slitting up or circumcision, at this stage, it is always better to wait till the inflammation subsides, and very frequently with the subsidence of the swelling the cause or contraction disappears and the parts become as lax and soft as ever. Frequently, cases have been taken into hospital for the purpose of having circumcision performed, and owing to the recumbent position, rest in bed, non-inflammatory diet, the swollen condition soon subsided, and the previous contracted condition of parts disappeared leaving no occasion for any operation. The next treatment to carry out in the early stage is to keep the patient in bed, raise or elevate the penis up against the abdomen, encompass the prepuce with strips of lint saturated in a cold spirit or lead lotion, clear out the bowels, with a saline purge, and feed the patient on slops or milk diet. With such a line of treatment assiduously carried out the patient in a very few days is well.

Paraphimosis.

This signifies a condition of the prepuce when it gets behind the glans penis becomes contracted and cannot be returned. An unnaturally tight prepuce is no doubt a predisposing cause of paraphimosis. As previously mentioned those suffering from slight phimosis very frequently get paraphimosis when indulging for the first or second time in sexual intercourse. Newly married men (anxious to discharge their conjugal duties) frequently get this condition. Somewhat excited

at the time they forget or become unconscious that the prepuce has in their exertions become contracted behind the glans. Not thinking anything can be wrong they allow it to remain for some hours in its displaced condition. The glans soon become swollen, and the preputial band becomes tighter and tighter behind the glans every hour it is allowed to remain in its abnormal position. Modesty with some still delays the matter, they are ashamed to apply for relief, and tell about such a very "delicate" subject. In this way a day or two is passed in the greatest agony, the parts swelling in proportion, and the tissues surrounding becoming distended with serum. At last through sheer pain they put aside their modesty and apply for relief. I may mention the earlier they apply to be relieved the better for them, and the easier would reduction be effected. Little boys playing together sometimes have the habit of playing with the penis and denuding the glans of skin. When manipulated in this way for some time the glans become congested and slightly enlarged, the skin is then pulled back and allowed to remain for a moment or so, and when an attempt to replace it is made it is found to the boys' consternation that "the skin will not go back." The little boy, not through modesty, but through fright, hides this condition from his parents for fear of a good whipping and goes for some hours, perhaps days, until the pain makes him tell of his sorry condition. It may also occur in another way. A young timid man goes in the way of impure sexual intercourse, he has heard of the different diseases contracted by such connections, he fears he may be the victim of such a misfortune, and on the slightest feeling or sensation felt about the top of his penis he frequently in the day takes occasion to examine the supposed cause of his anxiety, in this way he is constantly denuding the glans backwards and forwards, this unnecessary manipulation may cause irritation, perhaps balanitis, and the skin gets behind the glans through carelessness, and the patient through ignorance and fright allows it to remain so, it soon inflames, becomes distended with serum, and oedematous, and reduction by the patient impossible.

Symptoms.—The glans is very much swollen and congested from arrest of circulation. If any time has elapsed the prepuce surrounds the corona glans with a circular distended and contracted collar of serous and oedematous tissue, in front of this belt or collar the swollen glands is seen, and behind the penis becomes also enlarged and painful, so that the contracted band appears to be in a hollow or sulcus between the swelling in front and behind. The swelling behind is not as a rule as large as that in front, it however depends to a great extent on the length of time the condition has existed. If the constriction remains for any time ulceration soon sets in, to be followed by partial gangrene of the glans owing to complete arrest of the circulation and strangulation.

Treatment.—Many plans have been suggested for the reduction of paraphimosis, sometimes it is comparatively easy, at other times remarkably difficult. I think it is always best to administer an anæsthetic. The reduction is very painful, and no matter how patients are held by assistants they give a great deal of trouble, and become at times most violent, therefore I strongly recommend the patient to be rendered unconscious. I then recommend that the glans penis should be slightly pressed upon with the finger and thumb, so as to press as much blood out of it as possible, I then get a three-cornered or surgical needle, and I prick the distended mucous membrane all round and squeeze out the serum which flows out in large quantities, having made the parts very lax by this premonitory line of treatment. I grasp the penis (as in fig. 5) behind the constriction with my two index fingers, I press on the glans penis with the tips of my two thumbs and I gently carry out two ideas in the attempt at reduction, first I endeavour to draw forward the prepuce with my index fingers, and at the same time press back the glans penis with my thumbs. If this plan is patiently and gently carried out for a short time I have seldom seen

it fail. Some recommend the parts to be well oiled, I find this only renders the parts slippery to your fingers without doing any good. Manipulation in all cases I

FIG. 5.

First method to reduce Paraphimosis.

consider, if properly carried out, will suffice for reduction. If a prolonged careful attempt at reduction fails it has been recommended to divide the strictured portion. If this must be done, although seldom necessary, it is best accomplished by passing a tenotome flat subcutaneously under the strictured portion until all tension disappears, or an incision may be made from without through the skin down through the contracted band, or a director passed in as far as it will go under the contracting band, and thus divided in the usual way on the groove of the director, before having recourse to any division with the knife. If the penis is grasped behind the constriction with the finger and thumb of one hand and gently but firmly endeavouring to pull it forwards, the glans with the finger and thumb of the other hand is then pressed and squeezed backwards (as at figs. 6 and 7). If the serum has

FIG. 6.

Second method to reduce Paraphimosis.

FIG. 7.

Third method to reduce Paraphimosis.

been previously evacuated in the manner directed, the

patient asleep so as not to interrupt your manipulations, and this method adopted for say one or two minutes at a time, at the end of which to suddenly flip the prepuce forwards with a jerk once or twice, I have very seldom failed to effect reduction. Ioe has also been recommended to apply to the part to produce shrinkage before reduction was attempted. After reduction is effected all that need be ordered is a cold spirit or lead lotion to allay the resulting irritation and slight inflammation which, however, soon subsides.

SIX YEARS OF EXPERIMENT IN THE TREATMENT OF SYPHILIS. (a)

By CHARLES R. DRYSDALE, M.D.,

Senior Physician of the Metropolitan Free Hospital of London ;
Physician to the Rescue Society of London, &c.

It is not a little remarkable that the question of the best treatment of syphilis, a question which has been very seriously discussed during the last twenty years both in Paris, London, New York, and Philadelphia, does not even at this moment seem to have been fully solved. I say this with the more emphasis because there is a wide interval between the practice of such learned practitioners as Dr. Alfred Fournier, of Paris, and of Dr. Keyes, of New York, the former of whom is in the habit of giving to all syphilitic patients intermitted courses of mercury for two years, and the latter tonic doses of mercury for three or four years, and that of the modern Edinburgh school, represented by Dr. H. Watson, which seems to treat syphilis without mercury altogether.

Since the year 1497, according to Dr. Meryon, in his "History of Medicine," the use of mercury externally was practised by those who had occasion to treat that disease in its early times, when it appears to have been so greatly dreaded, and so fatal, whilst it was a new and hitherto unheard of disease. It was not, however, until 1570 that mercury was administered internally, and the first to do so was Paracelsus. It is, I presume, now nearly universally recognised that the rude practice of these early days, although probably often better than no remedy at all, was often a most dangerous practice, since, when it failed to cure the disease it often poisoned the patients, and even in many instances destroyed life by its severity. Unfortunately, too, this powerful remedy in large doses was used to treat gonorrhoea and chancroids with just as much vigour as when syphilis really existed, so that at the commencement of this enlightened century it is hardly to be doubted but that mercurial disease was a perhaps more formidable affair than even syphilis itself.

The natural history of syphilis at that time was almost totally misunderstood. Thus, Pearson, of the London Lock Hospital, writing in the year 1800, asserted that no case of syphilis could possibly recover unless mercury intervened. We all nowadays are well aware that thousands of cases of the disease get well, although the patients remain without any treatment at all.

In 1812 there was a campaign of the British against the French in Portugal, and Dr. Fergusson learnt at the town of Evora that the Spanish treatment of syphilis, which seems to have been more or less what is now styled "expectant," or, at any rate, without mercury, was much less fatal and destructive to the health of the Spanish troops than the English salvation so heroically employed at that date.

Since Fergusson's time a prolonged and careful observation of syphilitic disease, when treated with and without mercury, has shown that the disease, just like scarlatina, measles, and variola, may in some instances be an extremely mild disease, scarcely, if at all, affecting the health of the patient, even when no remedies are used, whilst at other times it is a very grave affection, destroying the health of the patient so completely that he may never afterwards know what health is.

(a) Paper read before the Medical Society of London.

Dr. Keyes, of New York, in his work on Syphilis (New York, 1881) says truly that syphilis is a self-limiting malady, and its general treatment may be, and often is, left entirely to Nature. Many a woman, and occasionally a man, gets syphilis without knowing it, and gets well again without any treatment at all. Indeed, it has been doubted by some whether treatment of any kind can shorten the duration of syphilis at all, for this disease will and does crop out at remote dates, after any and all kinds of treatment, and there is no positive or certain test which can be applied to a person to determine whether he is, after treatment, free from the disease or not. One fact about syphilis is known very well: it has symptoms, and certain drugs will keep down these symptoms; and it is as wise and as just to say that the quinine which breaks tertian ague only prolongs the disease by suppressing the symptoms (and some do assert this) as it is to hold that mercury prolongs syphilis by keeping symptoms in check.

The disease is self-limiting, and symptoms cease to appear, in the majority of cases, in the long run, with treatment, without treatment, sometimes despite treatment.

The aim of a rational treatment, therefore, must be to suppress symptoms and prevent them from doing harm during their existence; to control symptoms and prevent relapse without harming the patient in any way, and so to manage the disease that it may not be contagious during its existence by keeping down such symptoms as yield contagious secretions, that the patient may be able to marry as soon as possible and produce healthy offspring, and that the symptoms of the disease during their progress shall be restrained from leaving unsightly scars or damaging the tissues or organs during their existence.

Professor Sigmund (*Wiener Med. Wochensh.*, No. 10, 1879) thinks that many cases of syphilis do better without than with general treatment. He thinks that forty per cent. of untreated cases have such slight eruptive out breaks that the patients do not notice them at all whilst ten per cent. of those with obvious symptoms get well quickly by local measures alone.

Dr. Zeissl (*Wien. Med. Zeit.*, Nos. 1, 2, 3, 4, 1879) adopts the expectant treatment of syphilis for a time, and uses mercurials only in severe and obstinate cases. In short, he gives less of the drug. On all sides, too, testimony is coming in favouring a reduction in the amount of mercury used in the treatment of syphilis.

Dr. Ricord, of Paris, and his distinguished pupil, Dr. Alfred Fournier, however, have recently been very decided in the position they have assumed as champions of somewhat prolonged courses of mercury in every case of true syphilis, whether mild or not, commencing from the period of the indurated sore. This practice, they hold, is the grand means of warding off tertiary syphilis altogether. In an address delivered by M. Ricord a few years ago at the summer meeting of the British Medical Association at Birmingham, he said that he invariably gave a six months course of small daily doses of mercury to all his syphilitic patients, following this up by another six months course of iodide of potassium.

Dr. Alfred Fournier asserts that the "true cause of the passage of syphilis into the tertiary stage is doubtless the absence or insufficiency of treatment. Whatever certain authors have asserted, syphilis, when neglected, has every chance of arriving at the tertiary period, and, according to daily experience, the consequences of expectation applied to syphilis are truly disastrous." . . . "The most simple prudence obliges us to keep ourselves on guard in all cases, to advise a treatment sufficient to attenuate, if possible, the effects of the diathesis in the present and for the future. . . . My intelligence refuses absolutely to comprehend how a remedy can moderate all the effects of a poison and pursue this poison through all the organs where it pleases itself to hide, can cure even successive manifestations and discrete symptoms of the diathesis, without in any part finding itself in relation and conflict

with the principle of the diathesis, and with the organic cause of these symptoms. Ninety-four cases out of one hundred in my notes show that syphilis when treated is usually benignant. Among syphilitic patients treated with mercury not five per cent. are rudely attacked. When not treated syphilis is most dangerous, and we have too often to observe in our patients the evil effects of expectation in syphilis." ("Leçons sur la Syphilis," p. 1035.)

According, then, to Alfred Fournier, mercury cures iritis, syphilitic psoriasis, and neuralgia, and acts on the diathesis. He recommends intermittent courses of six weeks at a time for two years, *i.e.*, ten months of small daily doses of mercury in all cases of syphilis as a means of preventing tertiaries. These remarks of Dr. Fournier I listened to in his clinique at the Lourcine Hospital in Paris in 1871, and knowing as I did what an excellent observer he was, I determined to give this plan of his a patient trial.

The Tonic Treatment of Syphilis by Mercury.

Dr. Keyes, of New York, alleges that the treatment of syphilis should not commence until the first general symptoms of syphilis appear; the chancre with the accompanying glandular eruption is not enough to go by. (Keyes on "Syphilis." 1881.)

The idea of the tonic treatment used by this distinguished practitioner is, that mercury in small doses tends to increase the number of the blood discs, and to fatten the patient, even when continued for years, whilst large doses are anæmiating. The preparation he uses the most is the proto-iodide of mercury, as put up in Paris by Garnier and Lamoureux, in the form of sugar-coated granules, containing one centigram each (1-6th of a grain). Or he uses half grain doses of blue pill either alone or with one quarter of a grain of the sulphate of iron, or one-third of a grain of grey powder, or one hundredth of a grain of the perchloride of mercury for a tonic dose.

The patient, according to Dr. Keyes, is to take one granule after each meal for three days. On the fourth another is added, and after another three days another, until six granules, and even twelve, are taken daily. As soon as the daily dose produces griping or redness of the gums the patient has reached his "full dose," which, being anything but tonic, is to be used only in cases of emergency; but as soon as that is over the tonic dose is to be given, which is one-half of the full dose, or, better still, one-third of it. Thus, if the full dose for a female patient be one grain of the proto-iodide of mercury in the twenty-four hours, the tonic daily dose to be kept up for three or even four years, by the advice of Keyes, is one third of a grain. If iritis supervenes, or neuralgia, or headache, then the full dose, one or two grains in the twenty-four hours, is to be given, in fractional doses of one sixth of a grain.

In tertiary cases, except gummata, that author recommends a solution of biniodide of mercury in iodide of potassium.

R Hydrag. biniodid., gr. ss. ;
Pot. iod., ʒij. ;
Amm. iod., ʒss. ;
Syr. aur. cor., ʒij. ;
Tr. aur. cor., ʒi. ;
Aq. dest. ad ʒiv.

S. Teaspoonful well diluted with water after each meal.

M. Diday, of Lyons, in his "Histoire Naturelle de la Syphilis," divided this disease into *mild* syphilis, which required no mercury, and *severe* syphilis, which required that remedy. I think that subsequent experience has shown us that no case of syphilis can, with safety, be called mild; nay, some authors of great ability (among others Dr. Broadbent and Mr. B. Hill) go so far as to maintain that the so-called "mild" cases of syphilis are the very ones most liable to be followed by tertiary accidents. Dr. Alfred Fournier's cases of cerebral syphilis seem to corroborate this view, as most of them were in persons where syphilis had been very slight in its early stages.

That is also my own experience. But there are many exceptions to this pathological rule.

For many years I was unconvinced of the value of administering mercury in syphilis, and waited until iodide of potassium was indicated, a practice also followed by the late M. Dolbeau, and Dr. Perrin, of Paris. Like other observers I have cited, I found the majority of cases did very well on the expectant system. I should mention that any topical symptoms were treated topically, and iritis was treated by the frequent local application of atropine. There was, however, I found, a minority of cases thus treated, which were followed by tertiary symptoms, and, although these usually did very well under the iodide of potassium, I could not help wishing there was some medicine capable of preventing the supervention of tertiariam altogether.

It was at that juncture that Dr. Fournier, in Paris, and Mr. Hutchinson, in London, so categorically asserted that the omission of mercurial courses was the commonest cause of tertiary syphilis. At the same epoch, too, the idea that syphilis was caused by some minute organism capable of being acted upon by mercury became one of the possible explanations of the phenomena exhibited, and I was thus led to look on mercury as probably a parasiticide antagonistic to the existence of the supposed germ not yet discovered by the microscope, but plainly seen by the mind's eye of many competent writers on the disease, such as Hutchinson.

Acting on the germ theory, then, I have, since 1873, treated all my patients with secondary syphilis, and with hard sore, and enlarged inguinal glands, with very small doses of mercury continued for a long period. At the Rescue Society's Hospital, to which I am physician, when the patients are young women rarely over 20 years of age, I commenced this treatment at first in 1876, by giving to all cases of syphilis a pill twice daily containing one-third of a grain of the green iodide of mercury with two grains of the extract of hyoscyamus. These pills were made by Mr. Morson, of Southampton Row, a chemist who is well-known to be careful in his manufacture of the green iodide of mercury. Finding by experience, however, that this dose, although a small one compared with that recommended by Dr. A. Fournier, not unfrequently caused stomatitis and griping, I reduced it to one-sixth of a grain. This pill was administered to the syphilitic patients for, in many cases, in somewhat prolonged courses, such as ten months, a year, or even more, if they stayed long enough in the hospital. I continued this pill for some years, and have to report that I never found any unpleasant symptoms I could put down to mercury after the smaller dose was commenced, and that the patients uniformly improved in health and strength whilst taking it.

In 1878 I changed the form of pill to that of one grain of mercury with chalk, made up with two grains of the extract of hyoscyamus, and have continued to use this pill to all patients with syphilis, or with hard sore since that date at the Rescue Society's Hospital. It would be tedious to narrate the details of the cases which have passed before my observation in that hospital during this experiment. In some rare cases I have had rupia to combat, and iritis in a certain number. In many cases there has been notable disturbance of the general health, such as rapid pulse, sleeplessness, pseudo-rheumatic pains, anæsthesia and analgesia, loss of appetite, and emaciation. I have had a few cases of secondary and tertiary disease of the rectum. The latter class of cases have done ill; indeed, there are few of the symptoms of syphilis so likely, in my experience, to lead to a fatal result as tertiary disease of the rectum, as internal treatment is seldom of much service, and surgical treatment alone does any good.

As a general rule, my patients in the Rescue Society's Hospital have recovered quite thoroughly after the treatment above-mentioned, and have been enabled to enter some situation as domestic servants, to which they have been fitted by their education whilst inmates of the hospital in laundry and other domestic work. The diet there

is good and substantial, but no alcoholic drinks are given, and I never have ordered any to the patients, who, I think, partly from this cause have proved most polite and tractable, which is more than can always be said for the inmates of the Lourcine Venereal Hospital at Paris.

With regard to the treatment of tertiary lesions, I have very rarely required to treat such at the Rescue Society's Hospital, and as far as I know none of my patients have had such after leaving hospital and entering into service. I have been inclined to hope that this fortunate result was due to the small doses of mercury used in prolonged courses which has continually acted on the germs and prevented the supervention of gummy products. Had I to speak, indeed, of the treatment of tertiary syphilis from my experience of it in the cases of that hospital, I should have but little to say.

It has, however, been my lot to have to treat elsewhere a number of cases of periostitis, of sloughing sore throat, and even of cerebral syphilis and spinal disease, due to tertiary or gummy deposits. I must confess that in such cases I have been often puzzled when to withhold and when to administer mercury. As a general rule, I think all persons of experience will admit that gummata, whether in the soft or hard palate, or in any other organ, give way very rapidly to large doses of the iodide of potassium. In a case of threatened sloughing of the soft palate—for instance, when not an hour should be lost—I think it not allowable for the practitioner to give mercury, which has very little effect, unless he at the same time administers really effectual doses of the iodide. The iodide, indeed, in such cases is all powerful alone, without any mercury at all. Hence the rule, I think, should be, when we have such an important case, to treat which may suddenly cause perforation of the palate or nostrils, to pour in large doses of ten, fifteen, or twenty grains of the iodide of potassium several times in the twenty-four hours, until danger is past. Afterwards, we may administer again some tonic dose of mercury, such as that of one-hundredth of a grain of the perchloride of mercury, dissolved in ten drops of the tincture of the perchloride of iron, several times daily, continued for months if we think fit.

It would not be necessary to say anything special about the treatment of the primary lesion of syphilis, the hard sore, were it not that Mr. Jonathan Hutchinson, the most illustrious of modern British writers on syphilis, has lately put forward the opinion that the soft sore, or chancre, bears the same relationship to syphilis that an abortive vaccination does to a true one. If this were conceded, perhaps some one might be inclined to administer mercury in the case of chancroids, as used to be done before Bassereau wrote. For my part, I hold that soft sores have nothing whatever to do with syphilis, and that they are as local as ringworm or as scabies. They should, therefore, be treated merely by some topical application, such as a strong solution of nitrate of silver, or iodoform, &c., whilst the initial lesion of syphilis is the sure sign that syphilis has been in the system at least ten days, and probably a month, and consequently, if mercury is ever to be of service, clearly it is when the germs are commencing to spread through the system. Mr. E. Erichsen used to use the expression many years ago that mercury met the poison of syphilis in the blood and attacked it there, thus being the prophet of more recent views.

Some cases of secondary syphilis are very obstinate and difficult to cure. Thus, when the patient is racked in the agony of secondary rheumatoid pains, a severe attack of iritis may supervene, or headache of the greatest intensity. In these fortunately rare but most distressing cases, a very heroic and prompt treatment is needed. Very large doses of iodide of potassium or iodide of ammonium should be administered, and mercurial ointment may be rubbed in alternately in doses of one half or one drachm in the axilla, groins, or thighs, or soles of the feet; or one-sixth of a grain of the green iodide of mercury given every two hours in the twenty-four. Or Professor Henry Lee's plan of calomel vapour baths may be used in such cases.

Conclusion.

The treatment of syphilis commencing with the initial lesion ought to be continuous, and should consist of very small doses of some mercurial salt, continued for months. When severe symptoms are seen, inunction, calomel vapour baths, or fractional doses of the mercurial salt should be given for a week or so every four hours, in combination with large doses of the iodide of potassium, sodium, or ammonium. Atropia drops should be frequently used in iritis. In gummy deposits the chief curative remedy is iodide of potassium in large doses; but a tonic dose of some form of mercurial salt may be added as a germicide. If cerebral symptoms supervene, they are to be treated energetically with the iodide and with immersion.

Mercury in such small doses seems to do no harm to the general health, and there is much evidence to show that it is a tonic, which may be given even for years with advantage in some cases of anæmia. All cases of syphilis, mild or severe, should be treated by these small doses of mercury in order to prevent the supervention of tertiary symptoms or gummy products. The germ of syphilis has not yet been seen by the microscope, but it exists in all probability, and this is the rational account of the useful action of mercury and iodine, which are both germicides.

Clinical Records.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

Two Cases of Chorea.

Under the care of Dr. C. E. ARMAND SEMPLE.

T. G. E., a boy, æt. 11, admitted under Dr. Semple for chorea on December 27, 1882.

On Admission.—Pale, anæmic boy, dark under eyes. Tongue white at sides, red at tip and centre. Protrudes tongue in a jerky way, and withdraws it rapidly. Movements very marked and general, affecting the head, arms, legs, and body. Grasp of hands very unsteady; about equal in power. Heart's action irregular. A loud blowing systolic murmur at apex, followed directly by the second sound, which is clear, but reduplicated. Apex beat in the fifth interspace. Dulness extends from the third to the fifth rib. No marked dulness over the lungs. Rhonchi in the left axilla, and some crepitations at both bases behind. Slight cough. Abdomen normal. Spleen cannot be felt. Urine, sp. gr. 1032, acid, no albumen or sugar. Deposit of urates.

January 1st.—Ordered

Liquoris arsenicalis, ℥ij;

Mistura ferri perchloridi ℥ij. Ter die.

Perspires profusely.

6th.—Movements rather less; can pick up a knife with either hand.

10th.—Bruit at apex loud; also a short diastolic apex bruit which has nothing presystolic in its character.

21st.—Movements much less.

27th.—Movements hardly visible. Bruit not so loud.

February 1st.—Discharged nearly well. Temperature never above 98°6.

T. S. W., a girl, æt. 12 years 3 months, admitted under Dr. Semple on December 27, 1882. About two years ago had a slight attack, viz., awkward and odd in manner. This soon passed off. The present attack dates from three weeks ago; it appears to have been bilateral from the first. From being at first mere awkwardness it has gradually attained the present very severe stage. No history of acute rheumatism or chorea in the family. Girl has had pertussis and measles, but not scarlet fever or acute rheumatism. Two weeks ago had some transient pains in her head and legs.

On Admission.—Patient is a fairly well-nourished girl. Tongue somewhat white; protruded rapidly, and instantly withdrawn. Choreic movements very general, and severe, affecting the head, arms, legs, and whole body. The eyes also are not kept steady. She is unable to grasp the hand, both arms being thrown about when attempting to do so. She is quite unable to feed herself. She cannot speak

distinctly, nor can she sit up without support. No dulness over lungs, nor any marked physical signs except an occasional rhonchus under the right clavicle. Heart's action thumping; no bruit. Impulse in the fourth intercostal space. Abdomen normal. Urine 1030 sp. gr., acid, no albumen or sugar. Temperature normal.

December 28th.—Ordered

Liquoris arsenicalis, ℥iij.;

Misture ferri perchloridi, ℥ss. Ter die.

30th.—Complains of headache.

January 1st.—Movements much less.

3rd.—Tongue when protruded is a good deal steeper.

Speech better. More control over the hands.

8th.—Movements less. Speaks intelligibly. Can pick up small objects with her hand.

9th.—Fed herself for the first time.

10th.—First sound of heart prolonged at apex.

13th.—Between second and third ribs to left of sternum, at the base of heart, the first sound is roughened. Can do needle-work.

21st.—To get up.

February 8th.—Discharged well. Temperature, 98° 8'.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 13TH.

The President, ANDREW CLARK, M.D., LL.D., in the Chair.

REMOVAL BY INTERNAL OPERATION OF A PIN FROM THE LARYNX OF A BOY, ÆT. 13, IN WHICH IT HAD BEEN IMPACTED THIRTEEN MONTHS, AND HAD CAUSED ANCHYLOSIS OF THE LEFT CRICO-ARYTENOID ARTICULATION.

DR. FELIX SEMON read notes of this case. The patient was a boy, ÆT. 13, who, on the 25th of November, 1881, held a pin head foremost between his teeth, when, during the act of laughing, it slipped to the back of his tongue. In his endeavours to get it out he pushed it still further down, and it became fixed in the left side of his throat. No immediate serious symptoms followed, but during the next twelve months he had several paroxysms of pain in the left side of his throat, difficulty of swallowing solids, and spasmodic cough. These attacks were separated from each other by perfectly free intervals; they got, however, more and more severe, and finally on two occasions short and slight paroxysms of dyspnoea were associated with them. The boy was then (October 30th, 1882), brought to St. Thomas's Hospital, and admitted under Mr. Sydney Jones, who examined him under chloroform, and felt the point of a pin through the mucous membrane of the lower part of the pharynx on the left side. Dr. Semon then made a laryngoscopic examination, which resulted in the discovery that the pin was not, as had been so far supposed, impacted in the œsophagus, but in the larynx, and that its point only projected into the gullet. The point, vividly contrasting in colour with the surrounding bright red mucous membrane, was seen to project about 1-8th of an inch out of the arytenoid end of the left ary-epiglottic ligament in close proximity to the base of the left arytenoid cartilage. All the parts in its immediate neighbourhood (left border of the epiglottis, left ary-epiglottic fold, and left arytenoid cartilage) were seen to be considerably tumefied, and the left arytenoid cartilage remained immobile during phonation and respiration. The voice was perfectly normal; there was no dyspnoea. Mr. Sydney Jones consented to attempts at internal removal being made before an external operation was resorted to. After removal of the excessively large tonsils, and after short preliminary practice by means of the laryngeal probe, the boy tolerated the introduction of instruments, and on December 26th, 1882, Dr. Semon succeeded in seizing, under the guidance of the laryngeal mirror, the pin with a pair of lateral serrated forceps, and extracting it. Its length was found to be 1½ inches. There was no reaction after the operation. Four days afterwards it was ascertained by laryngoscopic examination that the immobility of the left arytenoid cartilage formed a permanent feature, and the epiglottis being much better elevated after, than before, the operation, it was seen that both the left arytenoid cartilage and left vocal cord remained, on attempted inspiration, immobile in the position of phonation. There was no dyspnoea; though the glottis only opened to half

its normal breadth. On the other hand, on attempted phonation, the right vocal cord completely joined its immovable left companion, and the voice was perfectly normal. The boy was dismissed on the fifth day after the operation from the Hospital. Dr. Semon remarked that as yet successful extraction through the mouth of foreign bodies after so long an impaction, and after the production of such considerable lasting changes in the larynx, as were observed in this case, had been but rarely reported. Apart from this there were two other points of intrinsic interest in the case. The first was the fact that without any sign of a *suppurative* process ever having taken place during the time of impaction of the foreign body, yet lasting and important changes (notably the anchylosis) had been produced, which distinctly pointed to an inflammation of the perichondrium having formed part of the inflammatory paroxysms spoken of in the history of the case. The process, which, in his opinion, had led to these changes was an *adhesive* perichondritis, the existence of which form of inflammation, so far as the laryngeal cartilages were concerned, was scarcely mentioned or even admitted in text-books on diseases of the larynx, but to which he had already (in 1880) drawn attention in a paper on the subject, published in the *Medical Times and Gazette*. The second, and, perhaps, most important point was the fact that so great a change as complete immobility of one half of the larynx had been produced, and was still present in this case, without the slightest alteration in either voice or respiration drawing attention to the larynx. Dr. Semon wished to urge this point, not only for the sake of this individual case, or of joint affections of the larynx, but with regard to a point of still greater importance, namely, the diagnosis of not only laryngeal, but also cerebral and thoracic diseases. He had shown elsewhere (*"Archives of Laryngology,"* 1881) that there existed a distinct proclivity of the *abductor* fibres of the recurrent laryngeal nerve to become affected sooner than the *adductor* filaments, or even exclusively in cases of acute or chronic, central or peripheral lesions, which affected apparently either the whole of the centres or the whole of the trunks of the motor nerves of the larynx. In such cases the laryngeal changes would consist in an immobility of the vocal cord, the muscles of which are supplied by the affected nerves, in the phonatory position, *i.e.*, in the position occupied by the left vocal cord in this case. It was evident that a similar absence of all symptoms, subjective and objective, might attend such a *neuropathic* change as existed in this case, in which the immobility was due to *mechanical* causes, and the natural conclusion from this was that the absence of all abnormal phenomena did not justify the inference of a perfect integrity of the part—in other words, that limiting the examination of the larynx to those cases only in which certain symptoms imperiously demanded its inspection meant, possibly, depriving oneself of a very important and valuable aid in arriving at a positive diagnosis.

ERYTHEMATOUS ERUPTION IN ENTERIC FEVER. (TWO CASES.)

DR. WHIPHAM related the particulars of two cases lately under his care in St. George's Hospital in which an eruption resembling that of scarlatina occurred. The first was in a cabman, ÆT. 36, who had been addicted to drink, but who for twelve months previously to his admission had been a teetotaler. The fever symptoms had commenced 14 days before, but the bowels had been regular and the motions natural. On admission the man complained of sore throat and headache, and had a bright erythematous eruption on the trunk, legs, and arms. The right tonsil was much swollen. His tongue was thickly coated, his pulse 128, and his temp. nearly 105. Next day the eruption was more marked on the arms and legs and had extended to the feet. On the third day after admission the patient became very restless and delirious, and the bowels which had been up to this date obstinately constipated were opened freely by a purge. The diarrhoea thus set up, though somewhat moderated towards the last, continued more or less up to the time of the man's death, *i.e.*, four days after his admission. No typhoid eruption was present. At the autopsy extensive ulceration of Peyer's patches was found. The second case was that of a child, ÆT. 4, who was received into hospital on October 6th, 1882. He had already suffered from scarlatina, measles, and whooping cough. Feverish symptoms manifested themselves on the day before his admission, and when he came under observation his temp. was 104·2, pulse 120. His tongue was red at the tip and edges, and the papillae protruded from a central white coat. On the day after his admission a red eruption was noticed on the

child's legs and he was therefore isolated. Next day the erythema had greatly extended and was very brilliant, the tonsils were red and swollen. The bowels were constipated. On October 10th (four days after admission), the eruption had faded considerably. The bowels remained inactive and a purge of Carlabad salt was administered, which acted freely. On the 11th the red eruption had disappeared. On the 13th the temperature reached 105, and the pulse 132; the child was delirious and had fits of screaming. The bowels acted once after castor oil, the motion being partly formed, and of a clay colour. On October 17th characteristic spots of enteric fever appeared, but there was now nor at any time any desquamation. From this date the symptoms were clearly those of enteric fever, and the child died on the 19th day after admission. The post-mortem examination revealed extensive ulceration of Peyer's patches and great swelling of the mesenteric glands. Mr. John Harley, in "Med. Chir. Trans." vol. lv., gives twenty-eight cases in which scarlatina was accompanied by swelling of Peyer's patches, but in only two of which ulceration was found, and also a second series of six cases in which scarlatina preceded enteric fever, and further narrates three cases of "mixed scarlet and enteric fever." He also quotes two similar cases recorded by M. Forget. Dr. Murchison says that in many cases of enteric fever the characteristic eruption is preceded by a delicate scarlet rash, and adds that "this is not peculiar to enteric fever but occurs in other forms of pyrexia." Sir W. Jenner speaking of a red rash in enteric fever says that the disease was mistaken for scarlatina. Dr. Whigham had lately seen a case of variola which was preceded by erythema of the abdomen and thighs. The question is, are these really cases of double poisoning, of mixed scarlet and enteric fevers? The absence of desquamation and the fact that an erythematous eruption is not uncommon in variola, pyæmia, and other forms of pyrexia, led to the conclusion that they are really instances of enteric fever preceded by erythema and not mixed cases of scarlatina and enteric fever.

Dr. MAHOMED said he was familiar with the occurrence of a roseolous rash in early stages of typhoid fever, and he had seen several instances of it which were not referable to scarlatinal symptoms. He mentioned the case of a patient admitted to the Fever Hospital under Dr. Cayley, for supposed scarlet fever, and who, six days later, showed evident signs of this disease, with high temperature, &c. The patient died, and, on post-mortem examination, marked lesions of the ileum were discovered, so that it was evident that preliminary symptoms on admission were not those of scarlet, but of enteric, fever. Recently another example of roseolar rash in a case of typhoid had come under his notice in Guy's Hospital, and his experience led him to the conclusion that marked desquamation did not at all follow as a necessary consequence of such rash any more than of those that occurred in typhoid. He was accustomed to teach students that there were four types of typhoid rash. The rash under discussion was, he considered, a form of eruption common to all forms of specific fever; in typhoid cases, however, there was not found a true roseola.

Dr. CAVAFY observed that rashes oftentimes produced by action of drugs might be quite indistinguishable from that of scarlet fever. Surgical scarlatina and the rashes of the puerperal state, and of menstruation, required also to be distinguished, and it was probable that all these forms of eruption were united by a common bond supplied by the connections of the nervous system, paralysis of the vaso-motor nerves affording a likely explanation of the phenomena. Important as he admitted it to be that diagnosis of erythematous from true scarlatinal rashes should be facilitated, Dr. Cavafy regretted his inability to suggest the means for making it. At the moment he had under his own care a patient who was taking salicylate mixture, and in whom an erythematous rash and punctate patches were observed, followed by sore throat, after the appearance of which the rash and punctæ disappeared, but a copious desquamation succeeded; eruptions set up by genuine medicines have also been seen to end in desquamation. Diagnosis in all these different conditions was consequently a most difficult matter.

Dr. ANDREW CLARK expressed himself convinced of the connection of the nervous system with the phenomena. He referred to the fact that exposure of the chest in nervous women during medical examination is followed by production of erythematous rash, the extent of which varies according

to the temperament of the patient; and he had proved that in many cases even desquamation followed afterwards. Dr. Clark said also that he had observed erythema occurring in the course of typhoid fever, and always in anomalous cases complicated by nervous symptoms.

Dr. BROADBENT said the only erythematous rash with which he was familiar as occurring during typhoid was that described by Murchison, and which could not readily be confused with scarlatina. He had, however, no doubt of the concurrence of typhoid and scarlet fevers, having witnessed it in many cases with marked desquamation. He regarded the second of Dr. Whigham's cases as one of scarlet fever preceding typhoid. Dr. Broadbent quoted a case in which every time the patient, a man of general nervous temperament, was stripped, a deep erythematous rash spread over the chest, abdomen, and back, fading away subsequently in patches.

Dr. ANDREW CLARK remarked that certain forms of erythema medicorum persisted for as long as thirty-six hours.

Mr. PAGE had seen cases, one of which he had published, of small-pox commencing in papular rash, which faded away as the typical eruption came out. In one of his own children chicken-pox had been preceded by the appearance of a scarlatinal rash (another child having previously suffered from chicken-pox alone), which rash faded away without desquamation. He ascribed these phenomena to peculiarities of the individual nervous system.

Dr. WHIPHAM agreed with Dr. Cavafy regarding the difficulty of diagnosing such rashes. He drew attention particularly to the fact that in the case of the boy no desquamation followed the eruption. He could not contest Dr. Broadbent's opinion of the case.

Mr. BERNARD ROTH, F.R.C.S., on

A CASE OF LATERRA L CURVATURE OF THE SPINE, ILLUSTRATING ITS TREATMENT WITHOUT THE USE OF MECHANICAL SUPPORTS.

(Photographs and Patient Shown).

The treatment employed has been described in the *British Medical Journal*, of May 13th, 1882. The following is a summary of that paper:—(1.) The importance of noticing osseous deformity, if any, of the spine and ribs, and whether the patient can be at once restored to the normal position, and if not, to what extent. (2.) If even slight osseous deformity be present complete cure is impossible. (3.) Even severe cases of lateral curvature often have no osseous deformity and can be at once temporarily restored to a normal position. (4.) A patient with confirmed curvature, with or without osseous deformity, is so habituated to the vicious position that his attempts to improve the spine increase the deformity unless instructed by the surgeon. (5.) Exercises of the spinal muscles with or without resistance by the surgeon while the patient is in the improved position are absolutely necessary. (6.) Good positions should be assumed at all times, especially in sitting, by means of suitable chairs. (7.) Moderate walking is beneficial. (8.) Lying prone or supine is not curative as the spinal muscles are not strengthened by it. (9.) All spinal supports, where the patient can by an effort maintain an improved position of the spine even for a few seconds, are injurious or useless. (10.) Swinging by the head does not strengthen the spinal muscles. (11.) By avoiding all vicious positions, by good ones being shown and maintained, and suitably prescribed exercises carefully practised, better and quicker results are obtained than by any other treatment hitherto proposed. *Case*.—Miss W., æt. 18, a student at the London Academy of Music, consulted me on March 4th, 1882, with this history:—Up to four years ago strong and well, then without any apparent cause she began to stoop and have backaches. Becoming gradually worse a Brighton hospital surgeon examined the spine, and finding curvature ordered the patient to lie down for two hours daily. At the end of a year as the patient became worse, an ordinary stee support with arm crutches was ordered. This had been worn for two years when she consulted me, the patient having become more deformed and suffering more. On examination, the patient presented confirmed lateral curvature, the whole spine being convex to the left, the right scapula more than two inches below the left, with considerable exaggeration of the cervico-dorsal antero-posterior convexity, causing poking of the head, flat chest anteriorly,

and undue prominence of the abdomen. There was slight permanent rotation to the left of the lumbar vertebrae, and slight increase of the convexity of the left ribs posteriorly. The patient although so apparently deformed could be placed in an almost normal position and maintain it by a great effort for a few seconds. The spinal support was ordered to be left off completely and a few simple exercises shown. December 8th.—The patient visited me for the second time. I found the state of the spine unaltered from the first visit. On December 20th these six photographs were taken. Above are the posterior, lateral, and anterior views of the patient in her habitual position; below, the corresponding views in the best possible position in which I could place her. The contrast between the two sets of photographs is very marked. The improved position always feels very unnatural at first as in this case. I maintain that no instrument yet invented can put or keep a patient in the improved position as shown in these three photographs. My prognosis was that she could be so strengthened by three months daily treatment that this temporary improved position involving such great effort when the photographs were taken, would become a permanent one without any effort, and that all pain would disappear. That is, practically, a complete cure although a slight permanent rotation of the lumbar vertebrae would remain. On December 23rd she began daily treatment. The same prescription of exercises as that quoted from the *British Medical Journal* was used. On January 13th the patient passed the whole day without backache for the first time for two years, and on January 16th the dress-maker had to widen her dress five inches across the chest. On examining the back I found the habitual position decidedly less deformed than on December 20th, less than a month ago. Her family notice a decided improvement in her position at home. Her appetite much better, especially at breakfast. Since January 20th the patient has been practising a prescription of which the "keynote" is a position with the right arm directed upwards, the left arm outwards, while the spine is rotated to the right and slightly flexed laterally to the left. The patient has continued to improve up to the present time, and I see every reason to expect that my prognosis of a practical cure at the end of three months' treatment will prove a correct one. Measurements of the arcs of the different curves in a case of lateral curvature are misleading if a note be not also taken of the improvement which can be effected by the patient's voluntary effort properly directed by the surgeon. Lastly, rough and ready gymnastic treatment such as advising a patient to swing on a trapeze with one hand higher than the other, or to use a skipping rope, is not to be compared in efficiency with systematic localised exercises (medical gymnastics) while the patient is placed in the improved position. The latter continued with attention to the avoidance of all injurious positions during the day constitute the most successful and rapid treatment of lateral spinal curvature.

Mr. HERBERT PAGE ON

A CASE OF TABETIC ARTHROPATHY IN WHICH THE TARSAL BONES OF BOTH FEET WERE INVOLVED.

This case was originally shown in the museum for living specimens at the International Medical Congress. The patient was a man, *æt.* 30, who, in October 1880, began to have swelling of his right leg and ankle. The foot gradually increased in size, and when first seen in February, 1881, there was great enlargement in the region of the tarsal bones, which were freely movable on one another in any direction. A month later, broken cones appeared on the sole, with an ulcer on the big toe. These sores were absolutely painless; as, indeed, was manipulation of his foot; a circumstance which led to the discovery that the patient was the subject of *tabes dorsalis*, the knee-jerk being absent, and the pupils presenting the "Argyll-Robertson phenomenon." There was no ataxia in gait. While under observation the left foot became affected in a similar way to the right, very rapidly and without pain. Four years previously he had severe lightning pains down the limbs, and two years before he had an illness called "nervous debility," of which the most noticeable feature was profuse vomiting every day for nine months; which began and ended quite suddenly without known cause as to its origin or its termination—a true gastric crisis. Attacks of a similar kind have occurred since the patient has been under the author's observation, and each of them has begun with

severe rigor, and been marked by the passage of large quantities of blood in the urine, associated, at the same time, with profuse vomiting, diarrhoea, and increased lightning pains. The patient has now been free from these attacks for some months, and the swelling of the feet has subsided. The feet however, are strangely deformed, owing to an alteration in the relative position of the affected bones. The other symptoms of *tabes dorsalis* remain the same, but there is still no ataxia. The history of this case having been given at considerable length, the author avoided speculation about it expressing the belief that he should not do wrong to be content at present with the clinical study of the disease. He pointed out the rarity of this particular form of arthropathy, only one instance of which had been seen by M. Charcot. Though rare, it had however, many features in common with the arthropathies affecting the larger joints. He laid stress on the practical importance of recognising these diseases in the surgical wards of hospitals where they are most likely to be found, the common symptoms of ataxia being often absent, and therefore rendering the diagnosis more difficult. One foot of his own patient would in all probability have been removed—so bad was it—had not the cause of the affection been accidentally revealed by the symptoms. The arthropathy has subsided, however, and left a useful, though deformed, limb. The occurrence of attacks of paroxysmal hæmaturia was a striking feature in this case, and the association thereof with the other symptoms of a crisis seemed to indicate that it was not less a symptom of the disease than the vomiting, the diarrhoea, and the joint affections. The history may therefore suggest a new line of observation and inquiry in the study of these cases of paroxysmal hæmaturia or hæmaturinuria, whose cause and origin are so often obscure.

Dr. ALTHAUS objected to the term "tabetic," urging that "tabic" would be a more correct form of the adjective.

Dr. BUZZARD suggested that cases of paroxysmal hæmaturia might be really instances of ataxia masked by the more prominent symptoms. A case had recently been reported in the *Lancet* in which gastric crises had been associated with Charcot's joint-disease, and which occurred in the experience of a provincial practitioner. In this case two healed perforating ulcers of the foot had been observed. Dr. Buzzard had lately met with another form of trophic disorder characterised by the appearance of ecchymosis beneath the left great toe nail, and subsequent falling away of the nail itself. The patient was ataxic, and had lost the corresponding toe nail of the right foot a year previously.

Dr. MAHOMED said he had under his treatment a case of locomotor ataxia, in which, in addition to atrophy of the optic discs, polyuria had been present at first, but which had almost disappeared at the time of speaking. This evidently pointed to renal neurosis.

Mr. PAGE said that within the past few days he had received a copy of a thesis by an American physician, in which spontaneous loss of the toe nails was described in connection with *tabes dorsalis*. Dr. Mahomed's case was interesting as an example of kidney neurosis in connection with *tabes*. He (Mr. Page) had purposely avoided to use the term "crisis;" he had seen the term "nephritic crisis" employed by a French physician. He was of opinion that paroxysmal hæmaturia might be associated with *tabes*; it was easy to ascribe it to the effect of cold.

[A patient was exhibited by Mr. Barker, on whom the latter had performed subperiosteal amputation at the hip.]

France.

[FROM OUR SPECIAL CORRESPONDENT.]

TYPHOID FEVER.—M. Peter continued his discourse on typhoid fever on Wednesday at the *Académie de Médecine*. He criticised particularly the doctrines of M. Pasteur relating to their application in surgery. He would admit that the researches of the discoverer of microbes were interesting in two points of view, which were that of natural history and pathological physiology; thanks to the works of M. Pasteur great progress has been made in surgery and obstetrics, but he could not see what services had been rendered to medicine by the so-called vaccinations. He did not under-

stand the denomination of Pasteurian vaccinations. Jenner inoculated a benign malady in order to ward off a grave disease, and that was vaccination; but M. Pasteur did not vaccinate, he inoculated. Before Jenner inoculation was practical, but it was found that often serious accidents followed, as the virus was in no way modified. Trousean thought to re-establish inoculation, but was forced to abandon it. M. Pasteur himself confessed that the direction of preservation against the virus of charbon did not exceed a year, and in many instances grave results followed the inoculation. In concluding, M. Peter said that, in his quality of philosopher and doctor he was obliged to affirm that all those pretended discoveries over which so much noise had been made have enlarged very little the circle round which the human mind revolves.

UMBILICAL EPITHELIOMA.—At the Société de Chirurgie M. Després communicated the case of a woman of sixty-five upon whom he operated for an epithelioma of the umbilicus. He circumscribed the tumour by two semicircular incisions, not only was the peritoneum attacked but also the epiploon, parts of which had to be removed. The tumour extirpated, he plugged the wound with the epiploon, replacing the cancer by an epiplocele. The patient left the hospital cured in a fortnight. M. Nicot said he did the same operation for a fibrous tumour of the umbilicus, in which he had also to open the peritoneum, but the patient had a good recovery.

TREATMENT OF FURUNCLES.—It is well known to-day that the matter of furuncles is inoculable spontaneously, and it is considered that this spontaneous inoculation is encouraged by the softening of the epidermis from the employment of the poultice so often used in this affection. The primitive boil becomes thus the point of departure for secondary ones, which manifest themselves in the neighbourhood. To prevent this inconvenience M. Labbé had the idea of employing successively for the dressing of furuncles a solution of chloral or phenic acid, but he perceived that this dressing, which was undoubtedly antiseptic, did not hinder the softening of the epidermis; it was thus he had recourse to collodion, a layer of which he placed around the furuncle. The result answered to his expectations, for no secondary evil appeared. M. Pasteur discovered the microbe of the furuncle which he found situated at the summit of the pustule. However, it will be borne in mind that secondary evils do not always depend on auto-inoculation, but often are the result of a diathesis at present not well understood.

CHLOROFORM BREATH IN GASTRIC DISTURBANCE.—There is a symptom of gastric disturbance in children which I have never yet seen mentioned in any text-book, French or English, and yet it is almost invariably constant and generally to be met with at the *début* of the affection, so that it may be considered as a sure premonitory sign, I mean that of the breath, which smells as if the child had freely inhaled chloroform. I have always found that this "chloroform breath" not only commenced with the gastric disturbance, but continued during the whole period of the malady, and that its cessation indicated also a cessation in all the other general symptoms, fever, vomiting, &c., and consequently a return to health. I have remarked this peculiar odour in children of every age, and once in a grown up person, it was then very strongly marked. I do not pretend to be bringing to light anything new, but I have never heard this peculiar symptom alluded to anywhere. In gastric derangement or *embarras gastrique* as the French call it, the breath has always been described as possessing a heavy odour, but that is very different from the chloroform smell which is sometimes

so pronounced as to be liable to induce the medical man to believe that the patient had been using the anesthetic.

ERRATUM.—It is hardly necessary to say that in the paragraph on the treatment of chronic diarrhoea by oxide of zinc which appeared in a recent number "ulceration of the intestines," should be substituted for "ulceration of the uterus."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 18, 1883.

THE MEDICAL BILL—A NEW DANGER.

IN common with most of those who have been engaged in watching and reporting the progress of the new Medical Bill, we have permitted one of the dangers surrounding it to pass unnoticed in the hurry of attending to what have been deemed to possess more pressing importance. The question of the title to be conferred on those who succeed in passing the final examination to be instituted under the Bill has, notwithstanding, again and again presented itself to our consideration; and ere long it had been intended to refer more particularly to the points raised in connection with it. Now, however, delay is no longer possible, for the Royal College of Surgeons, in a way that might very properly be commented on in severer terms than we care to employ, has seized on the weak points presented by the title of registration, and has urged on the Lord-President of the Council the desirability of substituting for it—nothing at all. Should our information be correct—and we have no reason to suppose it is other than accurate—a proposal has been made to those in charge of the Bill to amend the clause referring to titles forthwith, and to provide that whoever passes the examination in medicine, surgery, and midwifery appointed to be passed before registration shall thereby be entitled to go on

the Register of medical practitioners, but shall not by reason of it possess the right to use *any title whatsoever*.

Seriously as we have disagreed on more than one occasion with the action pursued by the Royal College of Surgeons, it has never fallen to us to chronicle such utterly unworthy opposition on its part as is shown by this attempt to emasculate a measure which promised so much real good. The consequences that must flow from the passing of a Bill pruned down to the extent dictated by the College are easily imaginable. One of the first will be depreciation of the *status* of those practitioners who are on the Register merely by virtue of the State examination. It is true they will be entitled to all the legal privileges attaching to registered medical men; but notwithstanding they will be as nameless for professional purposes as the most innominate of structures; they will possess no means of calling themselves medical men even, for absolutely *no* title will be accorded to them; and unless they transform themselves into perambulating book rests bearing the Register open at the pages wherein their names are recorded, they can never hope to appear in the world as members of an honourable profession.

On the other hand, whoever possesses a qualification which carries the right to employ significant titles and letters, whether obtained prior or subsequent to passing the registration examination, will rank incomparably superior to the equally registered practitioner, who, however, is debarred from parading any title indicating medical and surgical qualifications. The College, it is right to suppose, has had its wits sharpened by fear of losing its income, and with the quickness of dread has seen a possible escape from threatened obscurity. "If," it probably argues, "we can secure that registration shall confer no title, then our membership will continue, though it be but an ornament, and non registrable alone, to be a coveted qualification; and *we* shall continue to reap the rich annual income we have so long and so pleasantly enjoyed. In order, therefore, to bring about so desirable a consummation, we will not hesitate to convert, if by our efforts we can, a good and useful measure into a pitiful and ridiculous failure; it is surely better for us to preserve our fat and agreeable pickings, than it is to resign them after so long an enjoyment just for the sake of advancing medical reform. If the reforms proposed are brought about, we must suffer to some extent at least. We decide that we will not suffer at all."

This statement of the case is doubtless harsh and unsympathetic towards the College; and we are keenly alive to the fact that it is so. But we contend, that in the face of a danger so grave as that with which the progress of the Bill is now threatened, it is incumbent on us as guardians of medical interests to speak plainly out at whatever cost of pain or inconvenience. Moreover, the position of the Royal College of Surgeons as a great intellectual centre is so high and universally acknowledged, that its own safety is compromised by the action last taken by its Council. By as much as it is an important corporation, and by as much as it has exerted an influence in the past, it will be urged by those whom its suicidal attacks on reform are aggravating to

resistance, that danger lurks within it, and that its powers should be restricted within the narrowest possible limits. We should grieve to see this come to pass; but by-and-by the profession will demand to have its voice heard as well as that of a numerically small though unquestionably eminent minority; and when this time arrives, there will be little power of resisting the urgent claim that will be then advanced.

Had the College less glaringly insisted on its own rehabilitation; had it confined itself to objecting to the title of Licentiate of the Medical Council in Medicine, Surgery, and Midwifery, *per se*, it would have commanded sympathy in many quarters. Few of us, indeed, are agreed that this title is the right or proper one to adopt; and there remains much to be said ere it or a more appropriate one shall be accepted. But between selecting a better title in place of a bad one and abolishing the title utterly there is a vast and impassable gulf, and almost the only characteristic of the latter proposal is the cool effrontery of the proposers. It is, of course, evident that a vast majority of future practitioners under this Bill will affiliate with one or other of the medical corporations; but the scheme of the College would introduce the system of compulsory affiliation in every case except that of the men who would contentedly accept a position in which they would necessarily be regarded as distinctly inferior in *status* to the most ordinary possessor of a *qualification*, however easily obtained.

The attempt of the College is, in fact, an attempt to degrade the profession to the utmost depths, by introducing the most invidious possible distinctions. Should it by any ill chance happen that the proposed amendments pass into law, then, instead of improving the profession of medicine, legislation will have succeeded in plunging it back to a condition a hundred times worse than it was in 1858.

THE SHARE OF EACH LICENSING BODY IN THE MEDICAL WORK.

THE *status* of each of the licensing bodies in the Kingdom will no doubt be hotly debated when it comes to be settled what representation each of them should have on the divisional board which is to be established by the Medical Bill, and what the claim of each may be upon the surplus funds which the Medical Council will have at its disposal. The remark which fell from Lord Carlingford when he moved the second reading of the Bill, to the effect that the Irish Universities might be entitled to larger representation, would seem to indicate a contemplated amendment of the Bill in this direction. But we may ask, upon what ground should the demand of a licensing body to a voice in the divisional board be decided? The Scotch and Irish Universities have answered that they should have a prior voice in the board because they do the chief part of the licensing work of Scotland and Ireland; and as they have thus adopted extent of the licensing work done as the basis of assessment, it is essential that we should know what right to consideration each licensing body possesses on this ground.

With a view, therefore, of comparing the output of

Licentiates by each University and College throughout the Kingdom, we have tabulated for the three last years the annual returns made by these bodies to the General Medical Council—which returns can be found in the minutes of the Council—and we have worked out the average percentage of rejections by each body for these years. We have, of course, taken no cognisance of higher degrees, nor of special licences such as midwifery diplomas, and our calculations are made exclusively upon the results of the final examinations through which the Licentiates passed into the profession.

We place the various licensing bodies in the order of the amount of their licensing work.

Annual Number of Candidates passed at Final Examination for the Working Qualification of each Licensing Body, with Percentage of Rejections. Average of Three Years, 1879-80 81 :—

ENGLAND :	Passes.	Percentage of Rejections.
M.R.C.S. Eng....	421	34.2
L.S.A. ...	221	17.8
L.R.C.P. Lond.	92	20.2
M.B. Lond. ...	41	25.4
M.B. Camb. ...	18	32.8
M.B. Durham ...	15	15.2
M.B. Oxon. ...	6	18.5
SCOTLAND :		
L.R.C.P. & L.R.C.S. Edin.	155	40.6
M.B. Edin. Univ.	125	19.1

M.D. & M.Ch. St. And.	1	0.0
IRELAND :		
L.R.C.S.I. ...	110	25.5
L.K.Q.C.P.I. ...	99	19.8
M.D.Q.U.I. ...	63	28.0
M.B. Dub. Univ.	32	13.3
L.A.H. ...	31	27.8

These figures put beyond dispute that the Colleges do three-fourths of the qualifying work of the profession throughout the Kingdom. The London College turns out a greater number of practitioners than all the other licensing bodies in England put together. The Colleges of Physicians and Surgeons in Edinburgh also make as many Licentiates as all the other licensing bodies of Scotland combined, but they have very formidable competitors in the Universities of Edinburgh and Glasgow, which institutions monopolise more than a third of the Scotch licensing work.

In Ireland the disproportion between Collegiate and University work is equally well marked. The Irish College of Surgeons and Physicians send out between them nearly double the number of practitioners qualified by all the other Irish licensing bodies, and the College of Surgeons, standing alone, qualifies a considerably larger number of Licentiates than the two Universities put together.

We think, therefore, it must be admitted that, if

numerical preponderance in the work of licensing is to be the test of representation in the divisional board, the Colleges ought to send to each board the majority of its members. But it will no doubt be pleaded on behalf of the Universities that the Colleges obtain this numerical preponderance by ease of examination. If such an argument be used, we invite a comparison of the rejection percentages which we have given. In every country it appears that the proportion of candidates refused by the Colleges is, in almost every instance, greater than that which is shown by the University rejections. We shall not add further comment on these figures. We have produced them because we think it unfair that Universities should claim a position as licensing authorities to which they are not entitled, and should attempt to obtain a dominant influence in the medico-educational arrangements of the future by means of statements which, when examined into, turn out to be inaccurate.

THE MEDICAL BILL.

THE opposition to the principle of the Bill which, it was anticipated, would be embodied in a motion that the second reading should be deferred for six months, completely collapsed on Thursday week, and the Bill passed without any serious resistance the stage at which its principle was to be discussed. The Huxley proposal that all licensing bodies should continue to grant all the registrable diplomas they pleased, subject to supervision by coadjutor examiners appointed by the Medical Council, was not even mentioned in the debate, and may now be said to be *hors de concours*. The neck-or nothing opposition by Earl Cairns, which we were told would be pressed on behalf of the University of Dublin, resolved itself into a demand for reasonable amendment of the Bill at a future stage, and the promised thunder of opposing Lords was heard so mildly that it would almost seem as if those "who came to curse remained to bless."

The stage of Committee will be taken on Thursday (to-morrow) and we trust that the differences of opinion and interest between teachers, licensing bodies, and reformers may then be satisfactorily composed. The Irish Universities want a larger representation on the divisional board, and they ought to have it, if they can show that they are doing the largest share of the medico-educational work of Ireland, but not otherwise. The Rev. Dr. Haughton has published a manifesto in support of the claim of the Dublin University on this ground, and he, with characteristic audacity, takes credit for all the medico-educational work done by the Queen's University as so much good service performed by Dublin University.

We may, we presume, leave to the Senate of the Royal Irish University the duty of claiming credit for the chief part of that good service, and relegating the University of Dublin to the fractional portion of the work which has been hitherto performed by it. We do not contend that the right of a licensing body to representation on the divisional board should be judged altogether by the number of its licentiates, which Dr.

Haughton seems to consider the proper test of merit; but if output of practitioners is to be the basis on which the dispute is to be settled, we expect that the Royal Irish University, and not the Dublin University, will be the body to profit by this method of assessment.

The Irish College of Physicians—having very unwisely thrown itself into the holy war against the Bill of which Dr. Haughton had raised the standard—shares in the defeat sustained by that opposition. We hope that the College has thus learned the wisdom of seeking what is attainable, and will now devote itself to obtaining fair terms for the Irish School of Medicine and Surgery, and achieving a reasonable settlement of admitted abuses, instead of baying the moon in an unmeaning howl against reform.

We congratulate the profession on affirmation of the principle of the Bill by the House of Peers, and we trust that their efforts will not be relaxed until a good, thorough, and practical measure of reform has received the Royal assent.

Notes on Current Topics.

Poisoning by Gelsemium Sempervirens.

AN interesting case of this nature is reported by Dr. L. Friedrich, of Philadelphia. The patient was a little girl, *æt.* 14, who had taken by mistake a teaspoonful of the fluid extract of the drug. She had mistaken it for the bitter wine of iron, which she had been taking for nervous debility and weakness. Symptoms of dizziness, headache, great prostration, muscular relaxation, convulsions, a reeling and staggering gait, want of co-ordination throughout the entire system, widely dilated pupils, double vision, paralysis of the upper lids, and of the lower jaw, overflow of saliva from the corners of the mouth, congestion of the face, difficulty of speech, marked dysphagia, immediately followed, whilst the heart sounds were heard as if far distant. A semi-comatose condition supervened. The face from being congested became pale and death-like, the surface of the body cold, clammy, and finally covered with cold perspiration. There was a marked fall in the temperature of the body, but the number of degrees of temperature is not given. The pulse, at first quick and bounding, became feeble and thready. Respiration, at first normal, became gasping. The patient lost consciousness altogether. The treatment adopted was stimulation, and futile efforts to secure emesis. No stomach-pump was obtainable. Sulphate of zinc, mustard and water, and tickling the throat all failed. Strong infusion of coffee, artificial respiration on Sylvester's method, hot affusions, mustard to the extremities and spine, and the hypodermic administration of whisky, used seventeen times, were the means employed. Eventually the patient recovered.

THE use of Dudley House having been generously given by the Earl of Dudley for a concert last week, Madame Cellini has been able to hand over to Mr. Dobbin, the secretary of the Brompton Hospital for Consumption, the very handsome sum of £674 as the proceeds.

An Obstetrical Phenomenon—Crying of the Fœtus in Utero.

Dr. HARLOW, of Detroit, an accoucheur of forty-six years practice, and whose position, honourable character and credibility are vouched for by the editor of *Michigan Med. News*, reports a case of the above extraordinary, and apparently incredible nature. He declares that there is no possibility of his being mistaken or deceived. The following is his report of the case:—The lady was about forty years of age and in her fifth confinement, eleven years having intervened since giving birth to her fourth child. Upon digital examination, I found the waters just gathering, and after one or two additional pains the membrane broke and the amniotic fluid quite flooded the bed. It was a vertex presentation of the sixth variety, according to Baudelocque. Before the labour had further progressed, and while the head was yet engaged in the superior strait, the child made two distinct audible screams that could be plainly heard in any part of the room. Being greatly surprised at what I heard, I gently passed my hand up the vagina and found the head still in the superior strait. I made several ineffectual attempts to disengage it from its fixed position, but did not succeed in getting any descent of the head, and during this time the child had several spells of crying, the same as was heard at first, the tone and voice being unmistakably that of a child. During a lull, the pains did not entirely cease; and generally following each one the child would cry as before. I subsequently applied the forceps, and delivered the woman of a large female child. I afterwards took occasion to fully investigate this remarkable phenomenon. The patient told me 'the child first commenced crying four weeks before it was born, and kept it up at intervals till its birth, since which time it has not cried at all.' This lady declared and persisted that she went four weeks over her regular time. At first, she said, she was greatly surprised and alarmed, but as this peculiar freak of nature continued without producing any particularly alarming symptoms, she became so accustomed to its frequent repetition that her alarm vanished. To any doubting the facts stated, I can only say that I have reported my case accurately and truthfully in every particular, which I know to be so from personal knowledge."

The Fruits of Anti-Vivisection.

THERE has long been a false unwillingness among writers in medical journals to utter the truth concerning the necessary consequences of anti-vivisectionism. That this feeling is an unwise one there can be little doubt; and we are equally certain that a little wholesome awakening of the public to the danger they incur by pandering to sentimental opposition to science will be of real and lasting benefit. We are glad, therefore, to find our influential contemporary *Nature* addressing itself in downright earnest, and in simple and comprehensible language, to the task of enlightenment. Too much prominence cannot be given to the fact that, as Mr. Cartwright pointed out in his speech on Mr. Reid's Vivisection Abolition Bill, if experiments on animals are prohibited, then human beings must necessarily become the subjects of the roughest possible treatment. Refinements of research

under these circumstances, moreover, would be simply impossible, and every medical man would perforce become, whether he wished it or not, a vivisector of his patients; for it cannot be gainsaid that the attendant's duties to his profession are a higher claim than any advanced by the men and women who come to him for cure and relief. These truths are great and important, and they deserve to receive the utmost public attention at the present time.

Lady Doctors Wanted.

THE following encouraging information respecting the pressing need for female medical practitioners in other countries will be gratefully read by many of our English qualified women who find their hopes of practice at home most sorely disappointed. Miss Howard, M.D., an American, has for some time engaged in the practice of her profession in China, where she was fortunate enough to be called to attend the mother of a highly important official, Li Hung Chang, and subsequently the wife also of the same distinguished personage. Her fame as a physician has, it appears, spread over all North China, and Miss Howard is now besieged with applications to attend the wives and female relations of wealthy natives, who are entirely averse to consulting a foreign male physician, but who are nevertheless sufficiently alive to the value of skill and experience gathered in the Western schools. This eagerness for advice at the hands of a competent female doctor shown by the Chinese women may be considered as a phase of the general feeling of the kind prevalent in the East, and we trust that it may be accepted as a "call" to work by the growing number of young ladies who devote themselves to medical studies here at the commencement of each winter session.

American Opinion on the Medical Council.

OUR American contemporary, the *New York Medical Record*, devotes a leading article, in its issue for March 31st, to the prospects of medical reform in this country. After dwelling on the shortcomings of the Royal College of Surgeons and other examining bodies in the past, it gives brief attention to the Medical Council, which, being about to meet for a renewal of its usual business, so excellently described below, may find something more than cause for amusement in the following passage:—"The new Act will also create a reformed Medical Council, to which will be handed over the funds accumulated by the present one. It is to be hoped that the new Council will do more useful work for the profession than the present one has done. Most of its income has been devoted to the salarizing the members, who hold an annual sitting which begins and ends in—talk." Without flattering unduly, our contemporary has successfully evaded error in this description; its reference to "salarizing" being perhaps as correct a statement as any other that could be made of the application of the funds of the Council.

Royal College of Surgeons of England.

AT the regular quarterly meeting of the Council of the Royal College of Surgeons, held on Thursday last, after several reports had been received and other formal business transacted, an election to the Fellowship was

carried out in the cases of Professor Huxley and Mr. John Tomes. Both these gentlemen being members of the College of twenty years' standing, became eligible for election to the higher qualification without examination, and they, therefore, now enjoy the distinction this title confers upon its holders.

Death of Dr. Palfrey.

DR. PALFREY died on Tuesday, the 10th inst., at his residence in Brook Street, Grosvenor Square, after an illness of some weeks' duration. The deceased physician was well known as a successful gynaecologist and obstetrician, and was widely esteemed for his genial and generous disposition, while students particularly will feel that in him they have lost an earnest and enthusiastic friend and supporter. Dr. Palfrey had been for some years Senior Obstetric Physician and Lecturer at the London Hospital, where his loss will be keenly and for a long time felt.

The Jacksonian Prize.—Royal College of Surgeons.

AT a meeting of the Council of the Royal College of Surgeons of England, held on Thursday last, the above prize was awarded to Mr. Anthony Alfred Bowly, F.R.C.S., of St. Bartholomew's Hospital, for his essay on "Wounds and other Injuries of Nerves, their Symptoms, Pathology, and Treatment." The subject for this prize for the present year is—"The Pathology, Diagnosis, and Treatment of Obstruction of the Intestines in its various forms in the Abdominal Cavity," the essays for which must be sent in to the College on or before December 30th next.

Volunteer Medical Corps.

A MEETING was held on Wednesday last at Charing Cross Hospital in furtherance of a scheme, referred to in our last issue, to raise an ambulance corps among medical students. It was decided that such a corps should be formed, and speeches in favour of it were delivered by Surgeon-Major Evatt, Mr. Cantlie, and others.

Anti-Vaccination.

IN the House of Commons Mr. Burt inquired last week of Sir Charles Dilke whether it was the intention of the Government to introduce in the present session a measure to repeal or to mitigate the severity of the compulsory clauses of the Vaccination Acts,—and Sir C. Dilke replied that in the present state of public business he could not hold out any hope of legislation on the question during the present year.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 27, Bombay 37, Madras 36, Paris 30, Geneva 27, Brussels 23, Amsterdam 31, Rotterdam 31, The Hague 20, Copenhagen 30, Stockholm 23, Christiania 20, St. Petersburg 41, Berlin 24, Hamburg (State) 28, Dresden 27, Breslau 37, Munich 27, Vienna 34, Prague 34, Buda-Pesth 30, Trieste 37, Rome 30, Turin 27, Venice 31, Lisbon 33, New York 29, Brooklyn 23, Philadelphia 23, Baltimore 25.

Encouragement of Sanitary Research.

IN connection with the sanitary research scholarships and prizes instituted by the Grocers' Company, it is announced that any British subject, male or female, under 35 years of age may obtain one of the scholarships, and the £1000 prize is open without restriction to the whole world. A committee of selection, to which the duty of nominating scholars is confided, has been chosen, and includes the following well-known names: Mr. John Simon, C.B., F.R.S., Professor John Tyndall, F.R.S., and Dr. Buchanan, F.R.S. The first election will take place in May next, and the candidates must lay their claims before the committee during the present month.

A PAPER was read last evening at the meeting of the Statistical Society, by Mr. Noel A. Humphreys, on "The Recent Decline in the English Death-Rate, and its Effect upon the Duration of Life."

THE Emperor of China has received permission of the Government of India to send a certain number of youths to India, with a view to their studying European medicine and surgery at the Calcutta medical colleges. This is a bold step of the "heathen Chinese."

PROFESSOR FLOWER, F.R.S., delivered a lecture at the Working Men's College, Great Ormond Street, on Saturday evening, on "Fashion in Deformity." The chair was taken by Professor B. Thompson Lowne, F.R.C.S. This was one of the free popular lectures, and it was numerously attended. Tickets for the remainder may be obtained on application to the secretary, at the College.

THE election of a Professor of Practice of Medicine in the Irish College of Surgeons in place of Dr. James Little, who has resigned, is fixed for Saturday, June 2, the day when the College assembles to receive the annual report of the Council. The election will, in accordance with the charter, be by seven councillors chosen by lot. Dr. J. W. Moore and Dr. Arthur Wynne Foot, both physicians to the Meath Hospital, are mentioned as probable candidates.

It gives us pleasure to record the acquittal of Dr. Forbes, Demonstrator of Anatomy in the Jefferson Medical College, U.S., of the charge of complicity with the grave-robbers who were last fall tried and convicted. It would have been a great hardship had Dr. Forbes been convicted. He was doing what has been done, and is done, and always will be done; he desired to procure enough material to enable his students to properly prosecute their anatomical studies, and he went about it in the ordinary manner.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their population were—Salford, Birkenhead 18; Portsmouth, Halifax 19; Bristol, Sunderland, Newcastle-on-Tyne 20; Bradford 21; Derby, Wolverhampton 22; Birmingham, Brighton 24; Leeds, Cardiff, London, Bolton, Norwich 25; Edinburgh, Blackburn 26; Leicester 27; Plymouth, Preston 28; Huddersfield, Nottingham 29; Sheffield

Hull 30; Oldham 31; Liverpool 32; Glasgow 33; and Manchester 35.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class, per 1,000 of the population, were—from whooping-cough, 1.5 in Bradford, and 3.8 in Hull; from measles, 1.5 in Manchester, and 1.6 in Sheffield; from scarlet fever, 1.1 both in Preston and Leeds; and from fever, 1.4 in Blackburn, and 1.7 in Sunderland. The 35 deaths from diphtheria included 20 in London, 6 in Glasgow, and 5 in Edinburgh. Small-pox caused one death in London, and one in Newcastle-upon-Tyne, but not one in any of the other towns.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

SOMETHING WRONG SOMEWHERE.—At the first examination at the University of Edinburgh, just concluded, out of 200 students, nearly 100 failed to pass the test. Surely there must be something wrong in a system which produces so many failures; either the students are more idle than they are proverbially supposed to be, or the tests are too severe, or the teachers fail to attract the attention of their pupils. It may not be easy to explain the cause for so many failures, but there cannot be a doubt that the enormous size of the classes is detrimental to the proper supervision of the students, many of whom are mere boys. A professor may lecture to five or six hundred students, but it is absurd to suppose that he can teach more than a third of that number.

THE EXTRA-MURAL SCHOOL OF MEDICINE, EDINBURGH.—At a meeting of the lecturers of the Surgeons' Hall division of the School, held last week, the resignation of Dr. Argyll Robertson owing to his appointment to the Lectureship on Ophthalmic Surgery in the University, was read, and it was resolved that another meeting be held shortly to fill up the vacancy.

UNIVERSITY OF EDINBURGH SCIENCE DEGREES IN PUBLIC HEALTH.—The following gentlemen have passed the examination for the degree of Bachelor of Science in the Department of Public Health:—W. E. Bailey, M.B., C.M. (Glas.); James Crombie, M.B., C.M.; Francis William Grant, M.B., C.M.; W. A. Harrison, M.B., C.M.; H. Aubrey Husband, M.B., C.M.; and William Robert Smith, M.D.

EDINBURGH UNIVERSITY GENERAL COUNCIL.—We understand that Emeritus-Professor Mackay will be proposed as representative of the Council of Edinburgh University at the University Court, in room of Dr. Balfour, resigned. At the same time we hear that strenuous efforts are being made by the medical graduates to further the election of Dr. D. R. Haldane, late President of the College of Physicians, and formerly a Lecturer on Medicine in the Extra-Mural School.

THE LORD-RECTORSHIP OF THE UNIVERSITY OF GLASGOW.—The Liberal students of the University having communicated with Mr. Fawcett, M.P., and proposed that he should consent to allow himself to be nominated as a candidate for the Lord-Rectorship, the right hon. gentleman has complied with their request. The Conservative students have determined to run the Marquis of Bute, who has consented to be nominated as a candidate for the post.

THE GLASGOW MEDICO-CHIRURGICAL SOCIETY AND MEDICAL REFORM.—A *pro re nata* meeting of the Glasgow Medico-Chirurgical Society was held in the Faculty Hall, to consider the "Medical Act Amendment Bill in its relations to the interests of the profession generally." Professor Gairdner, President of the Society, occupied the chair. Dr. Ebenezer Watson moved the first resolution: "That this meeting approve of the Medical Bill in so far as it provides for the formation of a conjoint board in each division of the Kingdom to examine all candidates seeking registrable medical licences." Dr. Watson remarked that there were some minor matters in the Bill which he could not approve of, such as the representation at the Divisional Board and at the Medical Board, which was to take the place of the General Medical Council, but he thoroughly approved of the attempt which was made in the Bill to have uniformity of examination, and a general licence for all practitioners. The Bill, in its own way, proposed a thing which the profession had for long wanted, and which they still desired. He hoped they would endeavour to get the measure amended in its details, and to get it passed, because its general object was an extremely good and desirable one. The interests that were at stake—University interests and corporation interests—were very much *à d. interests*; and looking at it from a professional point of view, he held that the demand at present was for a shorter education and a cheaper licence. Let those of them who had the means and the talent afterwards seek for a higher education and for higher titles, and possibly for greater remuneration. Dr. Morton seconded the motion, which was unanimously carried. Dr. D. C. MacVail moved, in a long and forcible speech, "That this meeting is of opinion that the profession should have direct representation, not only on the Medical Council, but also on the Divisional Boards, and that in Scotland the profession should elect four of the eleven members of the Board, thus giving to the Universities four members, to the corporations three members, and to the profession four members." Dr. Lapraik seconded the motion, which was adopted. Dr. McEwen moved, "That this meeting is of opinion that when the Examining Board is instituted, there should be a rule that no candidate for the diploma of the Board be examined by any member of the Examining Board who may have been his teacher on that subject." Dr. Stirrin seconded, and the motion was also unanimously adopted.

ABERDEEN UNIVERSITY. — THE FIFE-JAMIESON GOLD MEDAL.—The result of the competition for this medal has just been announced, the medal being awarded to Mr. Patrick Whyte Rattray, Aberdeen, who gained 93.5 per cent. of marks in the combined written and oral examinations. Two other competitors were regarded as worthy of special mention—Mr. John Marshall Lamb, Aberdeen, 87 per cent.; and Mr. Francis Grice Jones, Denbigh, 80 per cent. The medal was founded by subscription last year in memory of the late Dr. Fife Jamieson, Demonstrator of Anatomy in the University, and is open to all students in the anatomy class.

GLASGOW SOUTHERN HOSPITAL.—Despite cogent criticisms against this scheme, progress does not seem one whit retarded. At a time when the social and moral effects of all hospitals are philosophically inquired into, this is saying not a little for the business enterprise of Dr. Eben. Duncan and his friends. The committee appointed for the purpose have made their award as between the competing plans, the premium going to the plan sent in under the motto "Hygiene," No. 1, the authors of which are Messrs. Campbell, Douglas, and Sellars,

architects, Glasgow. There were other very meritorious plans, and there were no less than 46 competitors.

ABERDEEN UNIVERSITY COURT.—This body met on Tuesday, the 10th inst., Dr. Bain, the Lord Rector, presiding. On the suggestion of the Lord Rector, the following resolution (endorsing a motion which had been adopted by the University Council at the instance of Professor Struthers) was passed without remark:—"The Court heartily concurs in the desirableness of an addition to our bursaries for the benefit of students of medicine, and has much satisfaction in recording the recent gifts by Mrs. Marr and Mr. Thompson, of Pitmedden, for that express object." Professor Geddes then moved "That the cordial thanks of the Court be given to Mrs. Marr and George Thompson, Esq., of Pitmedden, for their munificent donation to found medical bursaries." In supporting this resolution Dr. Geddes showed how much was wanted at the Aberdeen University to fit it in the highest degree for the work it should perform. In the course of his remarks he referred to the Universities Bill for the purpose of showing that, as it sought to divorce the Scotch Universities from the Treasury, an effort must be made on the part of the general community to supply the deficiency in funds that would thus be occasioned. Dr. Bain strongly approved of the vote of thanks to the two donors named. As to the Universities Bill, he remarked that the money given for University education was a mere trifle compared with the cost of some of the petty wars in which the country engaged. Other members thought the Universities Bill should not be discussed in this incidental way, and the subject was allowed to drop.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 7th inst., rose from 86 to 112, and the death-rate was 25 per 1,000 per annum. There were 12 deaths under 1 year, and 39 above 60, of which were 60 years. Diseases of the chest accounted for 60 deaths, and zymotic causes for 12, of which 2 were due to fever, 1 to diphtheria, 1 to scarlatina, and 2 to measles—the intimations for these diseases for the week being 6, 1, 28, and 15.

ACCIDENT TO A MEDICAL MAN.—On Friday, the 6th inst., as Dr. Meikle, of Melrose, was stepping into his conveyance at his own door, his foot slipped off the step, and the wheel of the machine coming in contact with his side, two of his ribs were broken. He is, however, doing well, and it is expected that he will be able to resume work shortly.

Obituary.

JAMES PALFREY, M.D., M.R.C.P. Lond.

We have to announce with deep regret the loss of one who, in the forty-sixth year of his life and in the prime of activity, has been somewhat suddenly taken from amongst us. By the death of Dr. Palfrey, not merely the London Hospital and its staff, but the entire profession, have been deprived of one of their most enthusiastic and able workers.

Dr. Palfrey was born at Deal in 1837, and at fourteen years of age was apprenticed to Mr. George Mason, of that town. He graduated M.D. in 1858, and became a member of the Royal College of Physicians two years later. In 1859 he married Ellen Mary Anne, the only daughter of the late Dr. Lever, and found in her the prize which, by the distinction he had gained as a successful student of Guy's Hospital and by his devoted attachment to her father, he had fully won. In 1861 he was elected Assistant Physician to the Metropolitan Free Hospital, and four years subsequently Assistant Obstetric Physician to the London Hospital. He now rapidly became known to the professional

world as a specialist of the first order—a specialist whose intimate acquaintance with that department he had selected to devote his attention to had been built on the sure foundation of a sound general knowledge of medicine and surgery. We are indebted to Dr. Palfrey for many steps in the advancement of obstetrics and gynecology, and to his genius and mechanical skill, displayed in the invention of several valuable instruments, among which may be mentioned incidentally his craniotomy forceps and tumour forceps, for many therapeutic resources.

On the death of Dr. Head in 1875, Dr. Palfrey was elected Senior Obstetric Physician to the London Hospital, and Lecturer on Midwifery and Diseases of Women in its Medical College—in these positions gaining the confidence of his patients, the good-will of his pupils, and from his colleagues the respect due to high professional attainments. An operator of unusual care and brilliancy, an able and eloquent lecturer, clear and orderly in his thoughts, and always commanding the attention of his audience, he was acknowledged by all who knew him to be a teacher of great capacity. Not merely was he a munificent supporter of every undertaking conducive to the recreation of students, but also supplemented the Obstetric Scholarship of his hospital by an annual gift of fifteen guineas to the second candidate. Another instance of the great interest he always evinced in the welfare of students is to be found in his valuable labour and advice which has contributed so materially to the successful formation of the Medical Union Society—the advantages of which as a bond of union between senior and junior members of our profession Dr. Palfrey ably set forward in a presidential address which he delivered at the inauguration of the Society at the commencement of the winter session. This was almost the last occasion on which Dr. Palfrey appeared in public. Even then a peculiar bronzed condition of his skin might have been noticed. He soon presented other symptoms of Addison's disease, and though evidently his health was fast breaking up, he nevertheless attended to his professional duties at irregular intervals throughout the winter, and quite recently had remodelled his lectures for the coming session. On the 6th of April, feeling much stronger than usual, he transacted business in his consulting-room. Unfortunately, he became chilled, and signs of hypostatic pneumonia and peritonitis appeared, to which complications he succumbed on the afternoon of the 10th inst. These conditions were verified by an autopsy made the following day.

Dr. Palfrey's remains were buried in the family grave at Norwood on Saturday afternoon, in the presence of a large and sympathetic body of mourners. Among those who attended the funeral, however, owing no doubt to a misconception as to the time fixed for the ceremony, no representative from the staff of the hospital to which the deceased was attached was noticed; and this omission of respect to one who has done so much to reflect distinction on an important school will be felt to be a negligence for which the authorities will be the first to feel regret.

This sad occurrence has caused a wide-spread gloom among his relatives and his numerous friends—a gloom which will spread still further. The public have lost a faithful servant, the profession one of its most eminent members, students a true friend, and the London Hospital Medical College one of its most successful teachers.

Literature.

MICRO-PHOTOGRAPHY. (a)

THE author of "Micro-Photography" tells us in his preface that the publication of his book has been undertaken with a view of encouraging the practice of the art, and assisting in its application to the various branches of science. He proceeds to thank his several friends for the assistance afforded him in its preparation, his especial thanks, he believes, being due to the Rev. G. B. Powell, "who revised all the proofs." Mr. Malley's confidence in his friend has, we fear, been a little misplaced, since we have rarely read through the pages

of a work containing so many typographical errors as that of the manual before us.

The first twenty-four pages of the book are devoted to the optics of the microscope, and these might have been omitted without in the least impairing its usefulness, as no one unacquainted with the use of the instrument is at all likely to take up with micro-photography. This portion also displays in many pages a great want of careful revision in describing optical phenomena, such, for instance, as occurs on page 10, paragraph 4. The author, in tracing the course of a ray of light passing from one substance through another, stops short in his description. It should read as follows:—"A part is reflected at the incident surface, a second is absorbed in its passage, a third is reflected at the second surface, and a fourth is transmitted." Again, on page 13, he speaks of lens A, fig. 10, as a "concave form and low curvature," whereas, if it is anything at all, it is a *divergent meniscus*; and on page 15 he bestows praise on an object-glass, because of "the ingenuity displayed in overcoming difficulties," but which has long been obsolete and thrown aside. On page 16 we learn that it is difficult to form an opinion of the penetrating power of an objective, whereas there is no difficulty in the matter, and this the author fairly well explains a few pages further on; and what is more singular is that, having admitted the superiority of the numerical method of estimating aperture, he at once reverts to the use of the old misleading term "*angular aperture*," when speaking of the magnifying power of the objective. By a further confusion of ideas, he says that "by using oblique light we may increase the angular aperture, since it enables the rays illuminating the object to pass through at a greater angle," &c.

We are not a little surprised to find a practical man saying of the mechanical arrangements of the microscope of the present day that they "are an insult to the skilled microscopist, and a means of perpetuating clumsy manipulations;" and of "all accessory apparatus," that they are "not only useless, but a decided hindrance to accurate investigation." Our own experience leads us to quite another and opposite opinion; and with regard to micro-photography, we know that Dr. Woodward's finest photographs were obtained with a Powell and Lealand's microscope, stand, and an achromatic condenser. It would require far more space than we have at command to furnish errata for the manipulatory part of the book, and for reconciling confounding directions, such as those on page 32: "The best light for micro-photography is sunlight;" and a little further, page 38: "Artificial light has so many advantages over sunlight." And, again, errors in quantities of chemicals employed, page 75; in the time of exposure, page 77; seconds for minutes; and in the method of preparing the plates, &c. But these, fortunately, are matters which time and practice will be sure to correct, as even the tyro in the art will discover. There is, however, a growing desire to employ photography in the domains of pathology, histology, and natural history; and since Dr. Woodward and Dr. Maddox have shown those who are not draughtsmen that micro-photography can be made to take the place of the pencil for the delineation of minute structure, in spite then of the defects alluded to, our thanks are due to Mr. Malley for his attempt to bring together in a handy volume the best known processes and economical forms of apparatus necessary to ensure success in micro-photography.

ST. BARTHOLOMEW'S HOSPITAL REPORTS. (a)

OF the present volume the best and briefest ver list that we can give is that it is fully equal to its predecessors, and so far, completes a medical series alike scientific and practical. There is a good paper upon fitful or recurrent vomiting, which is followed by a note on "Exophthalmic Goitre," by Dr. Wickham Legg, who gives full credit to Graves as the pioneer in describing this affection, resisting the certainly piratical claim of the countrymen of Von Basedow to that distinction. There is an interesting account of several cases in which deviations of the nasal septum, congenital and the result of injury, were cured after the lapse of years. There are some very good notes on orthopædic surgery by Mr. Howard Marsh; also by Dr. Harris, on "The Diagnostic

(a) "Micro-Photography." By A. Cowley Malley, B.A., M.B., &c. London: H. K. Lewis. 1882.

(a) "Saint Bartholomew's Hospital Reports." Edited by W. & Church, M.D., and John Langton, F.R.C.S. Vol. 18. London Smith, Elder, & Co. Royal 8vo. Pp. 439.

Value of Cardiac Murmurs." There is an account of the typhoid epidemic of 1881-2; and a very interesting paper by Dr. Humphrey on the tubercle bacillus in lung disease, in which he shows not only the infective character of phthisis under certain circumstances, but its power of secondary self-infection in the same individual. A very remarkable feature in the volume is the paper by Dr. Wahabam, "Is Trephining of the Skull a Dangerous Operation *per se*?" The writer goes through the literature of the subject most minutely, and gives a luminous abstract of 122 cases. His conclusion is that the mortality in trephining, properly performed with anti-septic precautions, is about 10 per cent. There is a most interesting (historically speaking) paper by Dr. Norman Moore "On the Physicians and Surgeons of St. Bartholomew's before the time of Harvey." Portions of this read like a romance—the account of Vicary, military surgeon to the Emperor Charles V., of Lopez, the Portuguese Jew, who was hanged for conspiracy to poison Queen Elizabeth, and the adventures of medical men in pursuit of their profession in the "good old times." It would be manifestly impossible in the limits of a review to do justice to this volume, which concludes with the Transactions of the Abernethian Society. We have said enough to show our readers the necessity of perusing it.

DRINK AND STRONG DRINK. (a)

We commence by smiling at the enthusiasm with which the eminent author took up the cause of total abstinence, but end by becoming convinced that there is a great deal in what he says, and some of his writings will convey conviction into a wider circle than the present volume. When the Blue Ribbon (teetotal) Army was first started it was the subject of unlimited ridicule, particularly among the London publicans, who adopted the following mischievous but humorous device:—A number of slips of blue ribbon were kept in a bowl under the counter, and, whenever a customer was leaving so drunk that he would be served no longer, the barman, pretending to help him out, used silyly to tie a blue ribbon in his button-hole. Bacchanalians used then to stagger home to the scandal of the elect and the mirth of the ungodly. This is all over now, and the Blue Ribbon Army exceeds four millions in number, and has brought the average annual consumption per head of alcoholic drinks from nearly four pounds sterling for each head of the population to considerably under three pounds, and there is no doubt that this great social revolution represents hundreds of thousands of happy homes and vast sums of money in the savings banks. If any candid reader will ask himself (after reading Dr. Richardson's little volume) whether alcohol can in any way be regarded as a necessary of life the answer must be in the negative; but at the same time, even the author himself admits that in certain diseases, in old age, and in certain constitutional conditions, it must be regarded as a potent and indispensable remedy. Here, however, he contends that it must be administered under medically-regulated doses of diluted spirit of a standard strength, and not in the vague and varying forms of wine, whisky, brandy, ale, &c.

"Drink and Strong Drink" is a careful and accurate historical, chemical, and physiological disquisition upon alcohol in all its forms. To the medical man there is nothing that is new, but to the layman much that is instructive, and that too couched in language of the utmost simplicity and clearness. All technical words or expressions are explained, and their derivations given; in fact, any average national school pupil of twelve ought to master the contents. This is Dr. Richardson's great contention, for he maintains that while it is creditable to be able to take alcohol in the strictest moderation, it is better for the healthy man to do without it altogether. What he advocates is that a race of boys and girls will grow up who will regard it as an evil, will never taste it or desire to taste it; who will in fact avoid it as we all avoid opium, looking upon it as a poison to be used under medical advice only.

We would commend to our readers the perusal of the curious story of the carman (p. 180) who lost a race by drinking a second "nip" of whisky; as also the graphic description of the effects of general teetotalism in two places,

one in Ireland (p. 189), and the other in America (p. 141). The first of these is described by the author, and the second by the late Hepworth Dixon. There is also a curious personal incident (p. 133) related by the late Dr. Cheyne, of Dublin. All these instances are well worth reading, but are too long to quote. The author truly says, "If you question those who indulge in strong drinks they will admit that, after the excitement from the wine or spirit has passed away, they are often depressed, irritable, or seedy, that the sad hours are much longer than the merry ones, and that there is no abiding enjoyment in their pleasure." Can anyone deny this statement?

We would not be surprised if this little volume in time doubles the number of the Blue Ribbon Army, and produces great solid effects. The decrease of the alcoholic revenue is likely to become a serious question for future Chancellors of the Exchequer, few of whom will be able to repeat the celebrated *bon mot* of the Right Hon. Robert Lowe when presiding over our finances. He had to unexpectedly provide several millions of money to pay the compensation to the United States awarded by the Geneva Congress. Being asked how he accomplished this without a loan, he wittily replied, "Oh, the British nation drank themselves out of that little difficulty." We doubt if the same will be possible twenty, or even ten years hence.

Notices to Correspondents.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

DR. DAWSON.—We can find no reference to the work in any published catalogue. Possibly you have not given the title accurately. We shall be glad to help you if it is possible for us to do so. The date of the inscription is 1791.

AN AGGRIEVED PRACTITIONER.—A patient has a perfect right to dismiss you and call in another practitioner, or his friends may do so, and you have no legal remedy; but this is an arbitrary proceeding, not often resorted to, so far as our knowledge goes. Of course, we are aware that patients are often unjustly impatient, and become so irritating to the medical attendant, that he is apt to ask, as did one of old, "Am I God, to kill and to make alive?" and your lost patient is probably one of this kind. But you can have no cause for grievance against your brother practitioner, who will probably be treated in the same unceremonious fashion as yourself.

DR. C. K.—You attach far too much importance to the accurate reproduction of the original. In most cases the resemblance is but slight, and it can never be considered sufficient cause for such extreme measures if the points insisted on are but slightly repeated.

A. B. (Birmingham).—Your supposition is correct. He is a member of the staff of St. George's Hospital, and has been identified for a long time with careful study of the disease in question. The work you mention is published by Messrs. Smith, Elder, and Co.

MR. CARRINGTON.—With two exceptions the numbers can be supplied to you. The lectures delivered by Mr. Hutchinson, "On Temperament and Diathesis," were published in our columns in 1882. Apply to the publisher.

CARITAS.—There is abundant opportunity for the exercise of such charity as you can dispense; in every crowded neighbourhood the claims of the poor call for sympathy, and an earnest intention needs no other direction than the promptings of its own good spirit.

GEORGE L.—Thursday, April 19th, at 2 p.m.

F. W. H.—Drs. Murrell and Ringer have conducted a large number of experiments with the drug. Consult their published researches.

AN ANXIOUS POOR-LAW OFFICER.—The Bill is not yet printed; and although we have a knowledge of its provisions, it would be inconsistent on our part to anticipate the measure. Doubtless we shall be in a position to give publicity to it in our next issue.

DR. S. E. B.—*Convolvulus majalis* is said to be superior to digitalis, in so far that it does not exhaust the contractility of the heart and arteries. We have it at present under test; but you will find sufficient reference to its value in the Lettsomian Lectures of Dr. Sansom, published in the early numbers of the present volume of the *Medical Press*.

A FIRST YEAR'S MAN.—Either of the works named will answer your purpose; you must get into the habit of forming a judgment for yourself. A casual examination at a library would have convinced you.

RHEUMA.—The subcutaneous nodules have been brought into considerable prominence since the narration of instances by Dr. Barlow at the Congress of 1881. Since that time several cases have been shown at the Societies, among others by Dr. S. Mackenzie, who exhibited the one you refer to at the Clinical Society of London.

A CASE FOR GENERAL SYMPATHY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—May I venture to direct the attention of the profession to the sad case of Dr. Hurford, which may be briefly stated thus:

Having filled the office of house surgeon for five years at Dr. Stillwell's Asylum, Hillingdon, in 1890 he obtained an appointment in the British Guiana Medical Service, and, having married, proceeded to

(a) "Drink and Strong Drink: a Series of Readings." By Benjamin Wapp Richardson, F.R.S. London and Glasgow: Wm. Collins and Sons, Limited, Foolscape Sq. Pp. 160.

Demetara. At the expiration of two years and a-half, through the ill-effects of the climate, he became mentally deranged, was compelled to resign his appointment, and, with his wife, to return to England. After three months' detention at Bethlehem Hospital he apparently recovered and was discharged.

Subsequently, with the assistance of friends, he furnished a house and purchased a small practice; but soon again his mind gave way, and it became necessary to place him a second time in Bethlehem Hospital, and to break up the recently acquired home.

The opinion of the medical men at that institution is that he will never be fit for his work again. He and his wife are entirely without means, and there are two children, one aged two years, and a baby nine months.

It is proposed to raise a fund which will, it is hoped, suffice to provide a home for the family upon whom this crushing blow has fallen. My excuse, if excuse be needed, for calling the attention of the medical profession to Dr. Hurford's case is its peculiar and exceptional sad-ness. A capable, earnest, and robust worker is suddenly cut off from his career by an attack of what is probably general paralysis of the insane, which renders him unfit for duty, though in the prime of life, and which makes it impossible that he shall ever again contribute to the support of his family.

I will only add that the Medical Benevolent Fund has given a donation of £20; other friends about £150, in sums of half-a-guinea and upwards, and that I shall be glad to receive and acknowledge any contributions, however small, towards the fund which is now being raised for Mrs. Hurford and the children.

I am, Sir, your obedient servant,

HENRY C. BURDETT.

89 Gloucester Road, Regent's Park.

SLIGHTLY ARCTIC.—Verchojansk, in Siberia, would appear to be the spot of all others on earth where the cold is most intensely felt. On Dec. 30th we are informed that the thermometer reached the lowest point ever observed, i.e. 63° below zero. In this favoured region a triple covering of reindeer skins is scarcely sufficient to preserve the blood from freezing. Each movement of the respiratory organs is painful, almost insupportably so to the throat and lungs. The breath exhaled congeals at once into minute nodules of ice, which, in rubbing against one another, produce a slight noise like the rustling of silk. It is said that a crow flying through the ice-cold air leaves behind it a long train of vaporous matter.

THE SECRETARY, UNIVERSITY OF EDINBURGH.—We have only space to insert the final "Pass-Lists" of the various Colleges, not the results of the preliminaries.

A CANDIDATE.—The two Board of Trade appointments referred to are limited to "registered medical practitioners who have served as medical officer on board passenger or emigrant ships for at least two years." The salary attached is £300, rising by £15 to £400 per annum. For further particulars we must refer you to the Marine Department of the Board of Trade in London.

A QUESTION OF CONFIDENCE BETWEEN PATIENT AND MEDICAL ATTENDANT.

JUVENIS asks our opinion on the following matter:—Parents bring a daughter whom they have observed to be alling to a medical man. She has missed two or three periods. On examination, the practitioner considers the indications denote early pregnancy. The parents have no suspicion. On intimating his opinion to the patient, she reluctantly admits, but implores the doctor not to reveal the state of matters to her parents, as she hopes to get married before they become aware of her condition. Now what is the medical man's duty when asked his opinion by the parents? Should he be candid with them, or should he keep the secret of his patient, as we are told the secrets of a patient should be inviolable?

[Our correspondent has been consulted by the parents, not by the girl, and he is bound to give them his opinion if asked. It would be useless for parents to call for medical advice if the doctor were precluded from giving it by the wishes of the patient. If, however, the girl had consulted our correspondent, he would not be bound or justified in communicating the result of his examination to her parents or any one else.—Ed.]

DR. E. SYMES THOMPSON.—Paper on "The Winter Health Resorts of the Alps" received, and will appear in an early number.

DR. YELLOWEES (Glasgow) is thanked for his note.

DR. C. (Bradford).—The volumes are now scarce, and will probably be very acceptable to the Society. A note to the Secretary will satisfy you on this point.

DR. T. F. PEARSE.—We hope to find space for the invention in our next.

DR. FRENCH.—Hazeline is most likely to be followed with successful results.

ECCLIASTICAL JUDGMENT IN MATTERS MEDICAL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Considerable interest having been excited by the reports of the sensational case in the Spanish Courts, in which the wife of the son of Marshal Serrano (formerly Prime Minister of Spain) sought judicial separation on the ground of her husband's incompetence, I am induced to send you a note on the subject from *La Presse*, as it possesses much interest for medical readers. Marshal Serrano's defence of the marriage simply amounts to this: that as, after examination, the Church pronounced his son perfectly competent to perform the marital functions, that therefore he must be. His wife, however, seemed to think otherwise. Your readers will excuse me if I give the note without translation:—

"*Un Procès à sensation.*—Le Maréchal Serrano vient de faire publier en brochure un long article justificatif concernant le mariage de son fils avec Mme. Campos. La science médicale a tout comme le latin des immunités d'expressions dont nos lecteurs ne devront pas s'effrayer. Voici la partie essentielle de ce document humain:—'Les docteurs José Benavides, J. Diaz Benito, et C. Fernandez y. Losada, membres de l'Académie Royale de Médecine de Madrid, ont examiné avec la plus scrupuleuse attention M. le Comte de San Antonio. De

leurs recherches il résulte que le dit comte est un jeune homme de vingt ans, brun, de constitution sèche, mais robuste, d'une bonne taille, et de tempérament sanguin. L'ensemble de toutes ses fonctions démontre l'accomplissement régulier de chacune d'elles. Les organes génitaux se trouvent à l'état normal, et leur examen prouve qu'ils ont fonctionné et sont à même de pouvoir, par la suite, répondre à toutes les exigences de la vie conjugale. Du reste, les habitudes de marche, de cheval, de chasse, d'écurie, indiquent les conditions physiques d'une parfaite virilité.

"Enfin, il faut ajouter à ces témoignages celui du tribunal ecclésiastique. Il paraît que l'examen du plus scrupuleux de ces juges a coïncidé exactement avec la décision de la science. Du moment que l'Église n'a pas dit 'non' à rien de ce qui a été dit."

Now, Sir, wishing to be in strict concordance with the last sentence, and the last words of same in above, I have nothing more to say.

Houghton-le-Spring, Durham,

Yours, &c.

April 6th, 1883.

J. O'FLAHERTY.

DR. RICHARDS.—The alkaline bicarbonates may be prescribed in all such cases with perfect confidence, and in considerable doses. We cannot recommend a more useful book than the one you name on the subject. Gant's "Surgery" gives full particulars of the operation you ask about.

MR. KAY.—Calcium sulphide has gained much reputation as an anti-suppurative; it has also been employed with success in many cases of an obstinate kind. It is quite worth your while to try it.

DR. W. (Bath).—We are much obliged for the information, and gratefully acknowledge the trouble you have taken in collecting it. The matter is under consideration, and will be reported on shortly.

PLUMBUM.—Mineral acids and alum cannot be prescribed with acetate of lead, because, producing a precipitate on addition to the latter, they are incompatible with it. The nitro-hydrochloric acid would probably be of equal service if given by itself or combined with a vegetable tonic.

MEETINGS OF THE SOCIETIES.

WEDNESDAY, APRIL 18TH.

HARVEIAN SOCIETY OF LONDON.—At 8.30 p.m., Dr. Symes Thompson, On a Case of Ectopic stimulating Relapse in Enteric Fever.—Dr. Dew, On a Case of Gastro-enteritis stimulating Typhoid.—Mr. Henry Morris, On Ten Years' Experience of Cancer of the Breast.

FRIDAY, APRIL 20TH.

ACADEMY OF MEDICINE IN IRELAND (Medical Section).—At 8.30 p.m. Specimen by card: Dr. McSwiney, Thoracic Aneurism.—Paper: Mr. Stokes, The Therapeutic Value of Nerve-stretching in Tabes Dorsalis.—Dr. McSwiney, A Fatal Case of Thoracic Aneurism without symptoms during life.—Mr. Story, Three Cases of Exophthalmic Goitre.—Dr. Walter Smith, Successful Removal of a Laryngeal Polypus by Voltolini's Method.

TUESDAY, APRIL 24TH.

ROYAL INSTITUTION.—At 8 p.m., Prof. McKendrick, Physiological Discovery.

Vacancies.

Baillieborough Union, Kingscourt Dispensary.—Medical Officer. Salary, £90, and £20 10s. as Medical Officer of Health. Election, April 24th.
Children's Hospital, Birmingham.—Resident Medical Officer and as Assistant Resident Medical Officer. Salaries, £50 and £-0 respectively. Applications to be sent to the Secretary not later than May 3rd.
Denbighshire Infirmary, Denbigh.—House Surgeon. Salary to commence at £85, with board, &c. Applications to the Chairman of the Committee of Management.
Leigh Local Board.—Medical Officer. Salary, £50. Applications to be sent to the Clerk on or before April 23rd.
Liverpool Royal Infirmary.—Resident Medical Officer. Salary, £100, with board and lodging. Applications to be addressed to the Chairman of the Committee on or before April 25th.

Appointments.

COLMER, P. S. H., L.R.C.P. Ed., L.F.P.S. Glas., Medical Officer for the Second District of the Yeovil Union.
HORTON, H., M.R.C.S., Medical Officer for the Knightwick District of the Martley Union.
LESLIE, L. G., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Third District of the Pembroke Union.
MCWILLIAM, J. A., M.D., C.M. Aber., Demonstrator of Physiology in University College, London.
MAXWELL, T., M.D. Camb., B.Sc. Lond., F.R.C.S. Edin., Surgeon to the E Division of Metropolitan Police.
MILLER, J. W., M.D., L.R.C.S. Ed., Certifying Surgeon to the East-end Factories, Dundee.
PALEY, W. E., M.B. Dur., F.R.C.S. Eng., Honorary Physician to the Peterborough General Dispensary and Infirmary.
WHITLOCK, A. W. F., L.R.C.P. Ed., L.R.C.S. Ed., Medical Officer for the Wells District of the Walsingham Union.

Deaths.

ALEXANDER.—April 10th, at Cheltenham, Archibald Alexander, M.D., J.P., Deputy Inspector-General of Hospitals, aged 71.
BLEASE.—April 14th, at Clairville, Aitricham, Thomas B. Blease, L.S.A. Lond., aged 78.
FLOOD.—April 12th, at Headford, co. Galway, John Coady Flood, M.D., aged 30.
PALFREY.—April 10th, at his residence, 29 Brook Street, Grosvenor Square, London, James Palfrey, M.D., aged 45.
WIDDUP.—April 9th, at Wexford, John Widdup, M.D., of 77 Wellington Road, and Penzance, co. Wexford, aged 81.

The Medical Press and Circular.

The Gulstonian Lectures

ON

STERILITY IN WOMAN.

Delivered in the Royal College of Physicians, London,
February, 1883.

By J. MATTHEWS DUNCAN, M.D., F.R.C.P.L.,
Physician-Accoucheur and Lecturer on Midwifery at
St. Bartholomew's Hospital, &c.

LECTURE III.—PART II.

ITS PREVENTION AND CURE.

THE regulation of desire and pleasure cannot be passed over without some remarks. Of the moral condition of those in whom these feelings are absent, or in whom they are in excess, I shall say nothing; and this silence is not because the moral condition is either unimportant or without influence on bodily health and on sterility, but because there is little that requires to be said. The healthy performance of the function of childbearing is surely connected with a well-regulated condition of desire and pleasure; and a well-regulated condition is not a reduction to a minimum or total absence, neither is it excess. I have already said that both desire and pleasure may be, and not rarely are, entirely absent; and it is my opinion, founded partly on the distinct testimony or concurrence of married women who are examples of the evil, that an education injudiciously ascetic, as it may be called, sometimes produces this deficiency, which is a source of much disappointment and disaster in married life; and this view is corroborated by what is quite certain—namely, that by indulgence the feelings may be, and not rarely are, produced or increased. Writing on sterility, Ambrose Paré gives directions how to increase desire with a view to conception. Equally important is excess of desire and pleasure, and its reduction within moderate limits is equally advantageous. Religion, morals, bodily health, and childbearing all combine to exalt the value and importance of moderation, and to show the evils of absence or of excess. The influence of separation of married people, or of living without cohabitation for a long time—a period, say, of several months—is very widely recognised; and it is probably dependent on the increase of

desire and pleasure in those who have little of either, and on the restoration of them in those who have been rendered nearly impotent by excess. This power of separation has appeared to me to be far more frequently operative in women who have had a family than in those who are absolutely sterile; and remarkable examples are not rare.

I have heard and read of, but have not personally witnessed, the disappearance of sterility after recovery from a fever; and this result is ascribed to the prolonged separation caused by the illness. The explanation may be correct, but it does not appear to be the natural one, for fevers are powerfully injurious to general health, and are known to disorder the ovarian and uterine functions.

I have already spoken of sterility as caused by marriage, especially in the young, and we know the sterility of prostitutes and the sterility of confined animals who couple freely or excessively, and it is probable that all these infertilities may have a bond of union in their being due to excessive desire and pleasure, or to excessive sexual indulgence, or to both combined.

In animals, especially in cows and mares, the semen is described as being not rarely expelled from the vagina soon after coitus; and this failure to retain is said to be, in some cases, owing to the animal not being duly in heat. Attempts are made to cause retention by dashing cold water over the buttocks and external parts. A like failure to retain the semen is frequently complained of by women, who describe it as coming away either immediately after coitus, and without leaving the horizontal position, or only on getting up. In either case women often attribute sterility to this failure of retention, and seek a cure of it with a view to fertility. Further, I have repeatedly been distinctly informed by careful women who habitually have this disagreeable imperfection, that conception has followed the rare occasions on which they have, as they noticed at the time, retained the semen. That this non-retention is often only partial is made probable by the occurrence of pregnancies in women who describe themselves as invariably suffering from it. It is rarely complained of except by the sterile, and I believe it is rare among the fertile. I have also a very strong impression, which I have no data to corroborate statistically, that it is especially common among those sterile women who have not sexual pleasure. I know nothing that modifies this condition, but believe that the production of sexual pleasure may have favourable influence.

It probably depends on the failure of the timely dilatation of the cervix uteri, and perhaps of the uterine openings of the tubes so as to admit the semen, and on the failure of the simultaneous production of a condition of increased temporary negative abdominal pressure, or of that aspiratory action of the abdomen which numerous old and recent authors invoke to explain the mechanism of fecundation; or it may depend on the failure of both of these conditions of ordinary successful coitus. Before leaving the subject I must add that the facts as to this profluvium seminis are not of the highest degree of security; for, so far at least as I am concerned, they are not more than the statements of intelligent wives. They are probably quite accurate, as they are certainly given in good faith; but it is possible that mucous discharges or glandular secretion through the ducts of Cowper or Duverney may be, in some cases, mistaken for semen.

The immoderately great consumption of alcoholic drinks by women, without their necessarily ever reaching the stage of drunkenness, is so common and so potent a cause of disorder and disease that it requires special mention. It is possible that much of the influence of this drinking might be justly ranked as part of mere overfeeding, whose injurious effects we have already spoken of, but this is far from certain. Indeed, while I am unable to give any strong evidence of the specially injurious action of alcohol, considered as an article of diet, I am much disposed to this view, being led to it by the good results in practice which I believe justly attributable to desisting from the use of it. The instances on which I rely are cases in which I have, by physical examination and other modes of inquiry, been unable to discover any evidence of disease of the internal genital organs. It would not make the conclusion more assured to enumerate cases which are not in number or other circumstances sufficient for a demonstration. But I may mention the leading features of one which could not but strike the most careless observer. This patient was brought to me to be cured of sterility, and, as some prolonged treatment was expected, she proposed to reside near me for a time. She was between twenty and thirty years of age, and had been several years living in fruitless marriage, absolute sterility. On two occasions, with at least two years of interval, I declared my inability to do anything against the sterility by local means because I could discover no disorder or disease of the womb or its appendages. Having some suspicion of too liberal use of alcoholic drinks, I recommended teetotalism. After the lapse of a few years the patient, now a happy mother, was again brought to me on account of some trifling complaint, and I was told as follows: Her drinking habits having increased, she was induced to go into seclusion with rigid surveillance, and in this she lived for about a year without any kind of alcoholic drink. When she came home again she had lost much flesh, but was in good health, and she maintained what were now teetotal habits. She immediately became pregnant, and pregnancy recurred. Such cases are not singular, and induce a belief in a special hostility of alcoholic drinking to fertility.

But alcoholic drinking has, in addition to the general or constitutional disorder which it produces, well ascertained power, in certain cases, to induce disease of the internal genital organs. That which is most easily and distinctly made out is chronic ovariitis. It often comes and goes in the presence or absence of the cause. When it is present sterility is not always a result, but frequently so, and its cure is often followed by the disappearance of the sterility.

We have, lastly, to consider the power of various local and chiefly uterine diseases and disorders, which have too much engrossed the attention of the profession hitherto. As I have already remarked, there can be no rational doubt that these local affections have a very limited scope of action; are, indeed, quite subordinate to the great causes of sterility affecting populations or classes. That they should have been the chief study of practitioners, as distinguished from statesmen or medical officers of health, is not only natural but in a sense just; for the practitioner cares not for the population or the class, but for the individual. If he is to do any good to the individual it is by discovering something amiss and providing a remedy that he must work. And where is a practitioner first to look for a special cause of sterility if not in the essential organs of generation? Here he finds several diseases, only in recent years the subject of scientific investigation, so-called ulcerations, displacements, strictures, subinvolution, and others, upon

which he easily finds a theory, generally a mechanical one, of the sterility which he at once proceeds to attempt to cure. If he fails to cure that does not discourage him; for, in the present state of therapeutics, the reputation of remedies is founded more upon faith than upon evidence.

The wisest practitioner is he who, giving due weight to all items of knowledge acquired in regard to a disease or an unnatural condition, sets limits to his faith or his expectations, and scrutinises the evidence on which a treatment is based, and this all the more severely if a certain result of the treatment is gain to himself.

Spasmodic dysmenorrhœa is the most striking morbid condition connected with sterility. It has its seat in the womb or its neighbourhood, and it is by most gynecologists regarded as a purely local affection, having as its cause obstruction to the passage of the menstrual blood from the womb into the vagina by local or general congenital contraction of the canal of the cervix uteri. The nature of the affection and the place it occupies in the theory of sterility make me believe it to be a local affection in only a very limited sense—only in the same sense as irregular action of the heart or of the bronchi is a local affection. Its frequency, apart from numerous other considerations, is enough to make the pathologist hesitate to accept an alleged deformity of the cervix uteri as its cause. Besides, when the very rare alleged cause has really presented itself in rare cases of real pin-point os uteri, dysmenorrhœa has not been always present; in my practice it has been always absent.

When evidence is led in favour of the obstruction theory of dysmenorrhœa the argument from the success of treatment by enlargement of the passage is generally held to be irresistible, and its force to be, if that is possible, increased by the cure of sterility which often accompanies the cure of the dysmenorrhœa, or, at least, follows the enlargement of the passage. The frequent success in curing or relieving dysmenorrhœa by this treatment, and the occasional success in curing sterility, are not matters of doubt. I have, indeed, no hesitation in saying that while many other pieces of advice are of great value in the treatment of the associated conditions of dysmenorrhœa and sterility, and in the treatment of them when not associated, this is the only medical interference that approaches in dignity to a cure. By this means, and chiefly by this alone, have cures such as concern us here been effected. In attestation of this utility we may cite the very great number of much-vaunted means by which the object is effected, by very many kinds of knives, many dilators, many expanders, many scissors, by tents of various kinds, by bougies of various shapes, all of them, when put into use, producing enlargement of a part or of the whole of the passage through the cervix uteri.

For those who deny the existence of contraction it is not necessary to say a word further against the explanation of cure by mere enlargement. For them that is certainly not the explanation. And it is easy to frame theories of the cure of dysmenorrhœa by enlargement of the passages, which may have the great superiority over that founded on obstruction, that they may also explain the cure of the associated sterility. Now, though the very simple cervical obstruction theory has been held sufficient to account for the sterility as well as for the dysmenorrhœa it is plainly in this respect impotent.

While it is doubtful whether any menstrual blood is regularly passed through the internal extremities of the tubes into the uterus, it may justly be held sufficient by the dysmenorrhœal obstruction theorists to consider the passage of menses through the cervix alone. But they, of course, extend their theory of causation and cure to sterility, and here it is semen whose passage has to be studied, not menstrual fluid, and the cervix is not the only narrowed part of the semen's route, for it must pass not only through the cervix, but also through the Fallopian tubes. And if the seminal obstruction theorists find impediments in the cervix with its comparatively considerable dimensions, such as to allow their knives or scissors to work, what will they say of the closed capillary channel of the internal extremity of a tube? Their cure of sterility merely enlarges a passage where there was no apparent mechanical obstruction, and leaves untouched a passage where there is apparent entire impermeability.

That the obstruction theory (in all except its absolutely certain applications, as in imperforate hymen—cases to which we here make no reference) is excessively exaggerated must be plain to everyone who regards the almost imm-

merable cases of fecundation in extraordinary circumstances—cases without penetration; cases of impregnation in peculiar conditions, through the rectum or through the urethra; cases in advanced uterine cancer; cases in proclivity with great cervical hypertrophy; cases in extreme distortion by fibroids; and others. In this matter the appeal to comparative anatomy is most instructive, and the argument from it very evident. The apparent mechanical difficulties in the way of the semen passing the cervix are, in some mammals, increased in an extreme and often a curious manner, without any consequent obstruction. To this matter Kehrler and Lott have paid particular attention, and have shown that the apparent mechanical difficulties affect the construction of the male organ in its relation to the female passage as well as the female passage itself.

To me it appears theoretically reasonable to connect the dysmenorrhœa and sterility with rigidity of the cervix, and the opinion that it is so is confirmed by its being actually discovered in most cases. Anyone familiar with the use of increasingly sized bougies in dilating the cervix must recognise the greater force required in dysmenorrhœal than in healthy women, and the increase of painfulness of the process as the force used, slight though it is, increases. The overcoming of this rigidity by temporary dilatation, not the overcoming of a mechanical obstruction, seems to me in some mysterious way to exert a generally beneficial influence on that part of the process of fecundation in which the uterus is implicated during insemination. For it may be held as almost certain that during the natural sexual orgasm in coitus the internal ends of the tubes, which we almost never see but as absolutely closed passages, are temporarily opened inside, and that the same happens to the cervix; and while it is probable that such wide opening of the cervix is not essential for fecundation, it must be held as facilitating it or rendering it more probable. Besides, this opening is an indication that the whole nervous arrangements as well as the physical organs are co-operating to produce the object in view. The opening here pointed out has, in its natural or healthy performance, and in the obstacle from rigidity, close analogy with similar processes going on during the premonitory and first stages of labour; and the dysmenorrhœal pains have analogy in the irregular painful and useless contractions and pains of these stages of labour, and of the hours immediately following delivery.

No other disease, local or presumably local, has such importance in the theory of sterility as spasmodic dysmenorrhœa. This great place is established by the frequent association of the two conditions, and by the probable connection of the dysmenorrhœal neurosis with profluvium seminis, with disorder of sexual desire and pleasure, and with other derangements of the sexual orgasm of coitus. But dysmenorrhœa has its place confirmed in a unique way, for its cure is universally admitted to be a distinct and direct step towards the cure of sterility, and this can be said of no other local condition.

During recent times no disease has more engaged the attention of gynecologists than the catarrh and peculiar changes of the cervix uteri connected with it, known generally by the name of ulceration of the neck of the womb. To it, even when in a very slight form, has been ascribed a very great pathological importance, and the Croonian Lectures of West seem to have had less effect in bringing the profession to a just judgment of its comparative insignificance than the overshadowing influence of some other temporary novelty. Among other evils which this very prevalent disease has been alleged to produce is sterility; but there is not a tittle of evidence that it has any special influence in preventing conception; and we have, for guidance as to this matter, our best help in the fact that conception and natural pregnancy are extremely common during its continuance. Among twenty-six cases observed by Grünwaldt, with a view to the study of the changes of the cervix uteri in the first month of pregnancy, he found only eleven with a quite healthy state of the cervical mucous membrane. Six had papillary and nine catarrhal ulceration, which no doubt existed before conception.

Almost identical statements may be truly made regarding versions and flexions, and I do not repeat them. But in this department of gynecology increase of knowledge not only tends to diminish importance, but to show that the great mass of versions and flexions are conditions of simple health.

The importance of those diseases which prevent the com-

mencement of uterine pregnancy, or render such commencement improbable or difficult, needs only to be mentioned. To Grünwaldt we owe a careful statement of the extent and potency of this class of diseases, and for them he, as already said, vindicates a morbid superiority over those conditions which prevent conception.

The diseases and disorders of the genital organs, whether they act in preventing conception, in preventing uterine pregnancy, or in interfering with its natural healthy progress, are operative in individual cases, and demand the most careful study of the practical physician, for it is chiefly through his power over them that he can hope to cure sterility. That in the early stages of the study of these diseases their influence should be exaggerated is natural. At all times there can be no doubt their study and treatment will be most important, not only on their own account, but with a view to the improvement of the general health. In the case of those local diseases which may be proved to have no special influence in diminishing fertility, their removal, by increasing the general health, will help towards a removal of sterility.

THE THERAPEUTICAL ACTION OF RHAMNUS PURSHIANA (CASCARA SAGRADA.)

By PROSSER JAMES, M.D.,

Lecturer on Materia Medica and Therapeutics at the London Hospital; Physician to the Hospital for Diseases of the Throat and Chest.

A FEW years ago a somewhat amusing controversy took place respecting an alleged new remedy indigenous to California introduced under the name of Cascara sagrada. This turned out to be the common Spanish name of the Rhamnus Purshiana, which flourishes on the Pacific coast of North America, and possesses properties allied to those of Rhamnus catharticus, and Rhamnus frangula. The plant is also locally spoken of as shittim, and some one has speculated that it is therefore the same as yielded shittim wood for Solomon's Temple. This, however, is a mere fancy. Hebrew scholars now translate shittah as acacia. The Rhamnus Purshiana was named after F. Pursh, who first fixed its botanical position. It is now widely used in the United States, and is becoming known in this country. It seems to be rather milder than the other rhamnins, and not so likely to disagree, although this may partly depend on the preparation. It is well-known that considerable changes take place in the other rhamnins during storage, so that it is better to keep them a year or two before using, and as the chemical qualities are rather similar probably the same rule applies.

Prof. A. B. Prescott separated three distinct resinous substances from the bark, besides a crystallisable body. Their relations to similar bodies found in the other rhamnins have not yet been determined. An extract is sometimes made, and is available for pills. I have used the fluid extract made by Parke, Davis, & Co., as well as an aromatic mixture prepared by them under the name "Cascara cordial."

The drug is recommended very strongly in habitual constipation, and for this purpose is usually given in small doses, once, twice, or thrice a day. In full doses it is an efficient aperient. It takes ten or twelve hours to act, and therefore is most conveniently given at bed-time, when used as a simple purge. It will then act the next morning. Usually, a drachm of fluid extract will act as freely as an ordinary pill or a black draught. Now, many people dislike pills, and have a horror of black draught, and in many cases these doses are unsuitable. A liquid aperient, therefore, is often desired, and a teaspoonful of the fluid extract in water will serve the purpose. The only objection is the bitter taste. This is effectually disguised in the cordial, which is, however, much less active, the dose required being 4 to 6 drachms or more. This can be taken by the most fastidious, and rarely fails to act.

In constipation, quite small doses—sometimes called tonic doses—are recommended, 10 or 15 or 20 minims

twice or thrice a day a little before meals. The remedy is to be continued until the bowels act with regularity, the dose being gradually diminished rather than increased.

With regard to the mode of action, I have no doubt that it increases peristalsis. Yet it does not appear to do this to such an extent as to cause griping as we know buckthorn often will. Perhaps it also increases intestinal secretion. It may claim to be a cholagogue in some sense, for it certainly seems to add biliary colouring matter to the evacuations. It irritates so slightly that it may be given in hæmorrhoids, but I cannot help thinking that much must depend on the preparation, and that a badly made extract from fresh bark would be as uncertain, and as liable to gripe and irritate as some specimens of buckthorn. If the *Rhamnus Purshiana* prove destitute of the acrid resin which probably causes these symptoms, it will be a great advantage. I will add one or two illustrations of its use.

1. A young woman of 23, with laryngo-bronchial catarrh—taking small doses of Dover's powder at bedtime. To counteract the constipating effect cascara cordial also given in two drachm doses. Three doses failed under these circumstances. The next night \mathfrak{zj} . of fluid extract—was followed next morning by two free evacuations.

2. A gentleman with laryngeal catarrh was taking morphia. The bowels became rather confined, acting only on alternate days. The motions scanty, pale, and putty like. He had hæmorrhoids, and the intestinal canal was so sensitive that very small doses of any aperient produced extreme distress. Was therefore unwilling to take them. He tried \mathfrak{zj} . of cascara cordial at bed-time. It acted once, producing a coloured stool of soft consistence without griping. Thus encouraged, he next night took a double quantity, \mathfrak{zss} . This produced some griping in spite of the morphia, but not much. It caused two evacuations, soft, and of deep brown colour. He has often taken a dose since, and can always get rid of the putty or clay stools by one or two doses.

3. An elderly lady with habitual constipation. One drachm of the cordial twice a day. In this case it did not suit—sometimes acted too freely, at others not at all. After a few doses it gave rise to frequent movement for little effect, and she therefore refused to take more.

INDIAN MEDICAL NOTES.

By Surgeon-General C. R. FRANCIS, M.B.,
M. R. C. P. Lond.,

Late Professor of Medicine in the Medical College, Calcutta, &c.

Malpraxis in Native Indian Surgery.

A HINDOO beggar was one morning brought to the hospital of the 37th N. I., then stationed at Nusseerabad, in Rajpootana, in the hope that something might be done for his left leg, which was in a very remarkable condition. From Poupert's ligament almost to the knee, all the skin, with the subcutaneous tissues, had been removed. There being no fasciæ, the several muscles hung loosely in their places; the femoral artery was seen pulsating in its upper and middle third; in fact, it was quite possible, with a pair of forceps, to demonstrate every muscle, nerve, and vessel situated on the front of the thigh.

The poor man told me that he had consulted a native surgeon on account of rheumatism in his leg, and that the man had applied some leaves bruised and made with water into a poultice. This was fixed upon the thigh in front, and allowed to remain for some hours. The part soon became very painful; and, when the poultice was taken off, it was found that the skin had become violently red and inflamed. After a few days it, said the poor man, dropped off. No doubt a huge slough had formed, and become detached. On inquiring for the native

surgeon, he was *non est*. Fearful of consequences, he had either left the neighbourhood, or concealed himself for the time. The beggar did not linger long. I had thought of amputating at the hip-joint, but there was diseased structure above, the mischief from the application having extended; and the state of health was against it. I could not ascertain what plant the leaves belonged to, exactly; though from the description I believe it was the *Calotropis gigantea* (*vern mudar*), one of the *Euphorbiacæ*. An acrid milky juice exudes from every part of the plant if cut into. I have known this milk to be used for toothache, a drop being put into the hollow tooth on cotton-wool. I once met with a case, in a poor native, where it had been rubbed on the outside for an aching tooth, and caused violent pain and inflammation. The bark of the root of the dried plant powdered is sometimes used by European and native practitioners with great benefit in place of ipecacuanha in dysentery.

Fatal Shock from supposed Snake-Bite.

J. B—, an Eurasian drummer attached to the band of the old 37th N. I., of which I was then in medical charge at Nusseerabad, was sleeping on a cane matting outside his quarters in the lines on a very hot night in April. About midnight he was suddenly roused from his sleep by something creeping over one of his naked legs, which were only partially covered by the loose drawers usually worn at night in India. He immediately, having an innate dread of those reptiles, jumped to the conclusion that it was a cobra, and the bystanders who, in response to his cries, began to collect around his bed, not unnaturally thought so too; and he was treated accordingly. Incantations, such as are customary amongst the natives on these occasions, were had recourse to, and the poor fellow was flagellated with twisted cloths on the arms and legs, in view partly to rouse him but principally to drive out the evil influence (spirit!) that for the time being had got hold of him. This practice was continued—the crowd of course increasing—through the night till gun-fire (about 4 a.m.), when I was sent for. With the first light of dawn the cause of the fright was discovered in the shape of a harmless lizard—a species of *lacerta*—which was lying crushed and half killed by the side of the poor drummer. But it was too late. From the moment when he believed that a poisonous snake had bitten him till about an hour after I saw him, he remained in the same state of utter and increasing collapse, from which he never recovered. He died at 6 a.m. The drummer was not a strong lad, and the shock was too much for him.

Clinical Records.

GLASGOW ROYAL INFIRMARY.

Notes of a case of Congenital Malformation of the Heart, Opening between Aortic Valve and Right Ventricle.

Under the care of Dr. CHARTERIS.

Reported by Dr. McNish.

WILLIAM F., itinerant, æt. 53, whose social circumstances were of a most uncomfortable nature, was admitted on December 23rd, 1882, complaining of pain in the right hypochondriac region, and in the pericardial region. A fortnight before admission, while sitting quietly reading, he was suddenly attacked by a sharp lancinating pain in the right hypochondriac region. On admission he was found to be somewhat emaciated, with a yellowish tinge of the conjunctivæ, but the skin showed no appearance approaching that of jaundice. The countenance was anxious. He complained of great thirst and vomited nearly everything he took for the first few days. The respiratory system was normal, but on auscultating over the heart a well-marked V.S. murmur was heard most distinctly at the apex, and fading away as the stethoscope approached the base.

During the whole illness the patient only complained of

pain in the right iliac region, which was increased on pressure and for which he had poultices of conium applied, and afterwards hypodermic injections of morphia. Neither, however, gave relief. He had very little cough, and no expectoration; neither did he complain of any difficulty of breathing. There was no dusiness of the countenance, or swelling of the feet until the last few days. The murmur determined during life and heard loudest at the apex following the first sound seemed mitral in origin, and as such was considered. It was also faintly heard at the inferior angle of the scapula.

Post-Mortem.—Pericardium contained about two ounces of serous fluid, and over the right ventricle there is a localised thickening of the pericardium. There is slight hypertrophy both of right and left ventricle, accompanied by dilatation of both cavities. The pulmonary artery is dilated but competent (3.5 cm.), but there is no evidence of valvular disease. On the anterior wall of the right ventricle there is considerable endocardial thickening occupying an area of a square inch, and nearly corresponding in position to the pericardial thickening above described. The tricuspid valve transmits three fingers easily. The chordæ tendinæ of the tricuspid valves are threatened, and at the attachment to the papillary muscles there is considerable endocardial thickening, which in some instances spreads to some distance from the attachment of the chordæ tendinæ. The left curtain of the aortic valve is considerably enlarged, and the aorta itself is dilated, so that when slit open it measures 3½ inches. The right curtain of the valve is slightly thickened at the line of contact, and immediately under the curtain there is an opening communicating with the right ventricle. The margins of the orifice are rounded and very firm, and there is no indication of any valvular arrangement. It is a point worthy of note, that the endocardial thickening in the right ventricle corresponds in position to the pericardial thickening in the same ventricle. The margins and surrounding tissues of the orifice are firm and rigid, so it appears quite evident that the opening must have been patent at all times.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND. OBSTETRICAL SECTION.

A MEETING of the Obstetrical Section of the Academy of Medicine in Ireland was held on Friday evening, Feb. 23, at the King and Queen's College of Physicians, Dr. JOHN DENHAM, President of the Section, in the chair.

Dr. WILLIAM C. NEVILLE, Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

EXHIBITION OF SPECIMENS.

Dr. J. S. POOLE showed for Dr. Kidd the uterus, heart, and lungs of a puerpera who died suddenly on the sixth day. The post-mortem conducted by Mr. P. S. Abraham showed a small abscess at the junction of the right Fallopian tube with the uterus opening into the peritoneal cavity. Here the vermiform appendix and an epiploic appendage were seen adherent, the right ventricle of the heart was largely transformed into fat, the left ventricle hypertrophied with but little degenerative change; the valves and auricles healthy. A large clot was seen *in situ* completely blocking a primary branch of the right pulmonary artery for about 1½ inches. Dr. J. S. Poole also exhibited an anencephalous fetus, the second born of slightly premature twins, the first of which was born healthy and living.

Dr. J. R. KIRKPATRICK showed a uterus and appendages with large fibroid tumour in anterior wall.

Dr. WM. C. NEVILLE, Sectional Secretary, exhibited for Dr. H. Macnaughton Jones: (1.) Fœtus and placenta of sixth month, of which delivery complicated by deformed pelvis and transverse presentation was effected by version with removal of detruncated head by perforation and craniotomy forceps. (2.) A large fibroid polypus which sprung from the cervix uteri and filled the vagina. It was removed by the écraseur and obstetric forceps with perineal laceration. There was also a dermoid tumour of bladder from the same patient. (3.) A unilocular ovarian cyst and a multilocular ovarian cyst, both removed by operation.

LIVING SPECIMEN.

Mr. STORV showed a patient who had a symmetrically

placed supernumerary finger growing from each hand. A brother had a similar deformity.

Dr. ATHILL read a paper on

METRIA (SO-CALLED PUERPERAL FEVER).

He commenced by saying that our knowledge of the various affections included by the Registrar-General under the term "metria" was still far from perfect had, of late, been steadily increasing. It was now all but universally conceded (1) that there is no such single disease as puerperal fever properly so-called, that is, a specific disease in the same sense as scarlatina or small-pox; (2) that inoculations and absorption of septic matter conveyed from without formed a not infrequent cause of one form of metria, viz., puerperal septicæmia; and (3) that puerperæ frequently become self-inoculated by poisonous material generated within their own bodies either by the decomposition of retained clots or shreds of membranes or placenta, the resulting fever being by some called puerperal septicæmia. He held that the septicæmic form of metria could only be communicated from one puerperæ to another by the actual transfer of the pathogenic matter either by the hands of an attendant, the nozzle of a syringe, sponges, napkins, &c., but not by the medium of the air. To two points he drew special attention, the frequent occurrence of metria in puerperæ who are preyed upon by remorse or mental distress and the occasional outbreak of a very fatal, infectious, and essentially epidemic form of metria which he believed could not be due to septic absorption. The influence of remorse and mental distress was well seen in the high mortality attending puerperality in women who had been seduced; and if such cases were excluded he thought the mortality of the Rotunda Hospital would only amount to one-half its present rate. Here fretting and a quickened pulse were the earliest symptoms of danger, a severe form of metria manifesting itself after twenty-four hours. These cases of metria were usually due to self-inoculation, the putrid matter finding a ready inlet because of the deficient post-partum contraction of the uterus seen in such patients. Occasional outbreaks of an epidemic and very infectious form of metria were also known to occur, the disease spreading widely among the inmates of a hospital. He could not accept Dr. Evory Kennedy's explanation of these outbreaks as due to the aggregation of puerperæ, nor could he admit of their septic origin, since septic material was not communicable through the air. He held rather that these outbreaks occurring simultaneously with epidemics or other zymotic fevers were really examples of these zymotics specially modified by the physiological state of puerperal women. The infection of erysipelas could thus induce an attack of infectious metria in a puerperal woman, while conversely, such a form of metria could impart erysipelas to her offspring. In the same way scarlatina grafted on a puerpera might result in metria and not in scarlatina. This infectious form of metria tending to assume an epidemic character was therefore to be considered as consisting of specially modified cases of the prevalent zymotic disease. As strengthening this view Dr. Athill noticed the fact that in his experience bronchitis or pneumonia occurring in a puerperal patient was likely to be complicated by abdominal symptoms of the same kind as those which were seen in puerperal septic fever. These views he exemplified by a history of such an epidemic of infectious fever occurring in the Rotunda Hospital in August last, and which, in the author's opinion, depended for its origin and infectious character upon an imported case of typhus fever in a puerperal patient. The outbreak was completely stamped out by closing and thoroughly disinfecting the hospital for a fortnight. The severe symptoms and rapidly fatal course of this epidemic form of metria differ essentially from the more insidious and less painful progress of puerperal septicæmia, on the characteristics of which he dwelt at length, emphasising the good prognostic import of a furrowed, as opposed to a glazed and cracked, tongue during its progress. Diarrhœa, he thought, was in such cases by no means to be considered an unmixt evil. In discussing the treatment of the different forms of metria he observed that, while all but useless in the epidemic form, it was often of great service in the septicæmic cases. He formulated the following conclusions as founded on his experience:—(1) That a disease of a highly infectious nature, differing essentially in its symptoms and course from that the result of septic poisoning, and capable of being propagated in the same manner as other zymotic diseases, occurs

from time to time among puerperal women; (2) that this disease originates from the introduction into the system of a puerperal woman of the infection of some well-known zymotic disease, such as erysipelas, scarlatina, typhus, and probably typhoid fever, the action of the infection being modified by the peculiar state of the system, and of the blood which exists in puerperal women, and that it therefore develops in them an apparently totally different disease; and (3) that the disease thus originating can be stamped out with as great ease, and by the same means as are known to be efficacious in the case of ordinary zymotic diseases. He was satisfied, however, that the majority of cases of so-called puerperal fever are the results of septic poisoning, such form of the disease not being capable of spreading through the air.

Dr. McVIGAN stated he had seen a case in which nervous shock from the sudden news of the Phoenix Park murders had seemed to him to be the exciting cause of puerperal fever.

Dr. POLLOCK had lately been called to see two cases of fatal metria occurring one after the other in the same district, and attended by the same midwife. Both began soon after labour, as an erysipelatous rash over the gluteal regions, and he subsequently learned that the midwife's daughter was suffering from erysipelas during the time in her own house.

Dr. HENRY KENNEDY had formerly seen many cases in the Rotunda Hospital in which the sickness had preceded labour, and he had made *post-mortem* examinations in many fatal cases. He usually found the inner surface of the uterus in a state of slough, with but slight appearance of peritonitis. The tissues mostly attacked were the cellular tissues which, commencing in the pelvis and spreading up behind the kidneys were always in a state of complete slough.

Dr. FRASER recommended that hand, instruments, &c., used about a puerpera should be cleansed first in a solution of Condy's fluid and then in one of oxalic and sulphurous acids.

Dr. KIDD recognised the epidemic, and the septicæmic or pyæmic form of the disease. He had long been aware of the former as distinct from the latter. It usually began outside hospitals and spread into them. The last epidemic in the Coombe Hospital had followed only after the disease had been everywhere prevalent around them. At the same time typhus was very prevalent, the Hardwicke Hospital being unable to accommodate it, and other hospitals being proportionately full. The cases of epidemic metria were very rapid, very fatal, and commonly showed symptoms of the disease before or during labour. He had recently been consulted about a lady who had only survived delivery by a little more than twenty-four hours. She exhibited well-marked puerperal symptoms, abdominal pain, tenderness, vomiting, diarrhoea, and fever. Dr. Atthill had succeeded most remarkably in stamping out the outbreak which he had described so easily, that he (Dr. Kidd) felt some difficulty in thinking that those cases depend on epidemic rather than local, causes. He had always found it very difficult to eradicate a genuine epidemic of metria. During the last Coombe epidemic, that hospital was closed and thoroughly disinfected, yet on re-opening the epidemic again broke out. Again, the newly admitted labour patients were transferred to the entirely separate gynaecological hospital which was fitted up for them. There fever appeared, and deaths occurred; nor did readmission into alternate beds into the freshly disinfected and whitewashed labour wards put a stop to the epidemic, which died slowly away of itself. These facts seemed to him to show that it was not hospitalism which sustained the outbreak. This form often occurred concurrently with epidemics of scarlatina and erysipelas, but he could not state the exact relation between them. When a certain epidemic constitution prevailed, all sorts of zymotic diseases flourished. He did not accept Dr. Atthill's view that these different diseases could result in one another; that if they sowed typhus they would reap scarlatina or metria. As in cholera, the first cases of the epidemic were most virulent, after a time some, and then more patients, beginning to recover. The majority of septicæmia cases were, he believed, autogenetic.

Dr. MACAN said that of late the belief had been gaining ground that this disease arose simply from septic poisoning. He regretted to see Dr. Atthill subsiding into another belief. The connection between puerperal fever and such other fevers

as scarlatina was not proved, and led only to confusion. On the other hand it had been clearly shown that there existed a close connection between it and erysipelas, amounting almost to proof that it was, as Virchow had said, a kind of internal erysipelas. When puerperal fever occurred in a hospital it was carried in a variety of ways from patient to patient, and thus the epidemic broke out. The difficulty of their getting rid of the septic poison became very great. The disease was easily carried and in this way spread. He disbelieved in the miasmatic theory of its spread and held that auto-infection was very rare compared to hetero-infection. The puerperal wounds were closed before the lochia or retained membranes were likely to become foetid. Treatment of acute septicæmia was almost hopeless, though he employed antiseptic washings of the uterus. Prophylaxis was chiefly to be regarded. Doubtless, the capacity for absorbing septic poisoning was greatly influenced by the nervous condition of the woman.

Dr. NEVILLE (Secretary) had difficulty in accepting Dr. Atthill's view that prevalent zymotics might give rise to a peculiarly epidemic form of metria. If typhus or scarlatina gave rise to puerperal fever he saw no reason why lying-in hospitals should ever be healthy, since the students attending them daily, attended also the fever wards of general hospitals. The general practitioner also attended all sorts of cases including midwifery, and although it might be so, it had not been proved that his midwifery mortality was on that account above the average. Could puerperal fever itself derived from scarlatina infect a third person with scarlatina? Such a case would never be recorded. The majority of cases attacked during an outbreak were primiparæ, a fact which could be foretold on the septic theory, but which could not be explained on the modified zymotic one.

Dr. ATTHILL in reply, said that Dr. Kidd had shown cases in which women had been attacked by the fever before labour. He thought that in such cases the fever was caused by the infection of scarlatina, typhus, or erysipelas, specially modified by the woman's physiological condition. He did not say that all these diseases had a common virus, but he did believe that they might all cause an epidemic form of metria. This form of the disease he did not think was more frequent in primiparæ than in others. He believed it spread equally through a hospital as in the example he had given. It was quite distinct from the septicæmic form which chiefly attacked primiparæ, and of which 75 per cent. of cases were autogenetic.

The Section then adjourned.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 15TH.

B. WALKER, M.R.C.S.E., President, in the Chair.

THORACIC ANEURISM.

DR. DE BARTOLOME exhibited a patient, the subject of thoracic aneurism. The man was æt. 43; had been in the militia for twenty-one years. About twenty-one years ago he contracted syphilis. The sore on the penis lasted three months, and was accompanied by bubo. He presents no present symptoms of secondaries. He has been twice married. By the first wife he had two children, neither of whom presented any symptoms of being syphilitised. By the second wife he has had no children; she has had several miscarriages. No particulars were given as to her age, or the probable cause of these accidents. Five months before the present notice, he felt pain in his right shoulder. Shortly afterwards a conical swelling was noticed some few inches (two to three) above the right nipple, and a little to the N.E. This swelling, at first conical, has latterly become flattened and diffused; a distinct thrill could be felt in it; a well-marked systolic murmur was heard on placing the stethoscope over it. The voice has changed. The right pulse is distinctly weaker than the left. Throbbing of the vessels of the neck noticeable. Pupils irregular, the right showing marked dilatation, and acting sluggishly to the stimulus of light. The face seemed bloated and congested, and was suggestive of anxiety and some distress. Dr. de Bartolomé described its appearance as typical of the facial appearance in aortic disease. The man had been rather a hard drinker, thus completing a typical history of predisposing causes. Dr. Bartolomé is treating him with five-grain doses of iodide of potassium four times a day. The

man refuses to enter hospital, so that there is no chance of trying the rest and diet treatment. Dr. de Bartolomé thinks that the rapid penetration of the chest wall, with so little previous constitutional disturbance, is a point worth noticing; he anticipates an early and fatal ending. The case was interesting from its well-marked features, and in the existence of alteration of the voice and affection of the eye.

SECONDARY LATERAL SCLEROSIS OF THE SPINAL CORD.

Dr. BANHAM exhibited a man, *æt.* 44, who had recently come under his care in the Sheffield General Infirmary, presenting well-marked features of this form of disease. Twenty years ago he had had fits; eighteen years ago had syphilis, which left cicatricial marks behind. At that time he noticed weakness in the right hand and wrist. Sixteen years ago weakness of the right leg began, sensation becoming impaired in the paralysed limb. Two years later the voice altered, its tone becoming harsh and unpleasant. There are no active movements in the right leg. The forearm is pronated, and flexed upon the arm; the hand is flexed upon the forearm, and the fingers are strongly flexed into the palm of the hand; the limbs are cold. The extensor muscles of the leg prevail over the flexors. The superficial reflexes are diminished, and the deep reflexes are exaggerated on both sides, but mostly so on the affected side. The periosteal reflexes are easily obtained over the tibia and lower end of the radius; ankle clonus is also beautifully marked. Well-marked anaesthesia present on the affected side.

BRAIN THEORIES.

Dr. HARDWICK read a paper on the subject of cerebral circulation, based upon Dr. Moxon's Croonian Lectures for 1881, on "The Influence of the Circulation on the Nervous System," in which the influence of mere congestion in producing disease is called in question, and, in fact, denied altogether. The paper gave rise to a lively discussion, in which the PRESIDENT, Drs. LAW, MARTIN, and Messrs. BROWNING, and JAMES took part. Some of the members exhibited a manifest reluctance to abandon the old and convenient term, "Congestion of the Brain," as an explanation of some pathological conditions.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

THE PARIS MUNICIPAL LABORATORY.—It occurs to me that a brief description of this establishment may not be uninteresting to those of your readers who may be acting in the capacity of medical officers of health. This institution was erected in 1881, and in it all qualitative analyses are made gratis, the reports being given in the following words, "good, passable, bad (not injurious) bad (injurious)." A tradesman whose place of business is pointed out as one in which adulterated articles are sold, is visited by two officers, (inspectors). They request to be allowed to examine the products on sale, and do so, both microscopically, and chemically, on the spot, with the means they carry with them. If article appears to be adulterated, two samples, one for examination at the laboratory, the other to be preserved in case of dispute, are taken, and attested by the signatures of the tradesman and both officers. Suspected samples can be lodged at the nearest bureau of police where they are placed in a special chest for the purpose, and forwarded to the laboratory at the prefecture of police, by means of the prison van. Every article that enters the laboratory is analysed quantitatively, the result, however, being only made known to the sender on payment of a fee varying according to the nature of the substance, from five to thirty francs. It is upon the figures obtained in this analysis that the chief of the laboratory bases his opinion. Each analysis is registered in a book for the purpose which remains at the laboratory and forms part of an important collection. Photographic apparatus have been provided, affording the analysts the advantage of

putting before the eyes of the jury and judges a palpable proof of the detected adulteration, for instance, in pepper, flour, and confections, or showing them the presence of trichini, cysticerci, &c. The cost of the laboratory amounts to £5,200 thus divided:—

1 Director of the Laboratory	£240
1 Sub-Director	180
1 Analyst (1st class)	96
3 Analysts (2nd class), £72 each	216
16 Inspectors (1st class), £105 each	1,680
16 Inspectors (2nd class), £72 15s. each	1,164
3 Employés, Porters	200
General Expenses	192
Total			£3,968

The rest of the sum is applied to the purchase of instruments, books, &c. Drugs are not liable to be analysed at this laboratory. In France *pharmaciens* can only be inspected by members of the School of Pharmacy, who alone have the right of entering into their *officini*. It is interesting to note the report for last year of M. Charles Girard, director of the establishment, as a sorry evidence of misplaced confidence in what the public swallow. In butter alone, there were only eleven samples pure out of sixty-two examined. Preserved vegetables on examination showed the presence of copper in eleven out of 35 samples. Milk showed oatmeal, white of egg, dextrine, sugar, brain matter, oils, and fat. Wines showed oxide of lead, alum, salt, salicylic acid, and sometimes arsenic in liquids coloured with fuchsin. In the matter of wines M. Charles Girard values the loss annually sustained by the Treasury at more than £140,000. Beer showed picric acid, gall, aloes, colocynth, cocculus indicus, cubeb mixed already for use with nux vomica and carbonate of soda, strychnine, box leaves, juniper, &c. The report even mentions amongst various adulterating materials in different articles, *residus of secula manufactory*. It is pleasant to find that the endeavours of the laboratory have brought on a notable decrease in the number of adulterated articles sold in Paris and in France generally. One would like to see the crusade against adulteration and unsatisfactory conditions of food carried out even more rigorously than they are at present in Great Britain and Ireland. Healthy and health giving food is a matter of primary importance to the welfare of the nation. Money spent in securing so important a desideratum should not be spent with a grudging hand, nor should there be any soft-heartedness or leniency shown towards offenders against the adulteration law. Wilful dishonesty is certainly not to the credit of the nation amongst whom it is allowed to flourish. Practically speaking, the difference in cost, between the genuine and the adulterated article, is as much pocket-picking as if the often highly respectable, and possibly even *pious* vendor, were guilty of the felon's act of inserting his hand into his customer's pocket and taking the money itself.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 37, Madras 34, Paris 29, Geneva 26, Brussels 30, Amsterdam 32, Rotterdam 25, The Hague 27, Copenhagen 25, Stockholm 25, Christiania 17, St. Petersburg 41, Berlin 36, Hamburg 29, Dresden 25, Breslau 36, Munich 33, Vienna 37, Prague 41, Buda-Pesth 32, Rome 32, Turin 35, Venice 34, Lisbon 37, New York 29, Brooklyn 23, Philadelphia 24, Baltimore 24.

THE GENERAL MEDICAL COUNCIL.

THE Thirty-fourth Session of the General Medical Council commenced on Thursday last, under the presidency of Dr. H. W. Acland, F.R.S., who said that letters had been received from Mr. Teale, who was unable to attend in consequence of serious illness, and from Prof. Haughton, who was also unable to attend.

Dr. Acland read the following

PRESIDENTIAL ADDRESS.

Besides the ordinary duties of the Council, three special subjects demand your attention at this its thirty-fourth meeting. It is not necessary that any one of these should long detain you. Since it was not desirable to defer their consideration till a later period of the year, I have thought it well to arrange the present meeting so that it might be easily concluded before the Summer Session begins in the several Medical Schools.

The three subjects are as follow:—

- (1) *Alleged or proved misconduct on the part of certain practitioners*, which has been found to demand your judgment under Section XXIX. of the Medical Act.
- (2) *The Report of the Committee on Unqualified Assistants.*
- (3) *The Report on Professional Examinations*, which you directed last year to be forwarded to the Medical Schools.

I. The cases of alleged or proved misconduct of practitioners, which has been found to demand your judgment, are, I regret to say, five in number. They are not alike. The first is the case of Mr. Prosser, M.R.C.S.Eng., L.S.A., against whom the President and Fellows of the King and Queen's College of Physicians in Ireland have made the charge that, should certain facts be proved to be as stated by Mr. O'Leary, L.K.Q.C.P. Ireland (who had been committed for manslaughter on a charge wherein Mr. Prosser had given evidence in June, 1880), then the conduct of Mr. Prosser, socially and professionally, deserves to be termed "infamous." The Branch Council for England, to whom the case was referred on July 6 of last year, acting under Clauses 1 to 5 of Chapter XIV. of the By-laws of the Council, have come to the conclusion that there are not grounds for finding Mr. Prosser guilty of infamous conduct in a professional respect. The Branch Council will accordingly lay before the Council the evidence of the case, together with the opinion of the Solicitor to the Council, and their own resolution thereupon. The second case is one of a different character, and bears upon a subject of wider significance than that of a charge against an individual. This will hereafter come before you in another shape. It is that of Mr. Thomas Gray, M.R.C.S.Eng. and L.S.A., who, having been charged by the Medical Alliance Association with systematically giving false certificates of the cause of death in cases where he had never seen the deceased persons in their illness, was convicted at the Thames Police Court in the single case of a false certificate as to the death of Minnie Lucy Wadsworth. No further evidence can be obtained than that bearing on this one instance, and the case therefore against Mr. Gray rests on this single conviction. The Council will be called upon to decide whether on that conviction they will remove the name of Mr. Gray from the Register, under Section XXIX. of the Medical Act. He has been summoned to appear before you to-morrow. The third case is that of Mr. Hoar, M.R.C.S., who, having been co-respondent in a suit tried before the Divorce Court, was found guilty of adultery, and damages were assessed at £5,500. The co-respondent was in the relation of family medical attendant to the respondent and her husband. This circumstance separates it from the cases in which no such professional relation existed, and which, therefore, are only amenable to the ordinary civil actions at law. Mr. Hoar has been summoned, under Clause 4, Section XIV. of the By-laws, to appear before the Council to-morrow at 2 o'clock. Fourthly, Mr. Arthur Augustus Sadgrove has been summoned to appear to-morrow before the Council on account of a conviction before the Wallingford magistrates, and in respect of an accusation made by the Faculty of Physicians and Surgeons of Glasgow, to the effect that he had claimed diplomas which he was not entitled to use, and in respect of other facts which will be laid before the Council in a report from the Branch Council for England. It will be for the Council to decide whether the facts adduced bring Mr. Sadgrove

within the scope of the 29th section of the Medical Act, and if so, whether the Council will see fit to remove Mr. Sadgrove's name from the Register. The fifth case, that of Mr. Dry, is another which relates to the signing of false death certificates. Mr. Dry has also been summoned to appear. It has to be here noted, in respect of the judicial duties of the Council, that a practitioner whose name had been erased from the Register under Section XXIX. of the Medical Act, has presented a petition by which he seeks restitution to the Register. Up to the present time this power has been exercised by the Council in four out of the thirty-seven cases in which names have been removed from the Register for criminal offences or professional misconduct. Some doubt was, at your last meeting, expressed as to whether it is within the terms of the Act to restore a name so removed. Counsel's opinion, that the power to restore does exist, will be laid before you. It will be for the Council to consider whether it sees fit on this occasion to exercise this power, as it has done in the before-mentioned four cases. I have been led thus briefly to sum up these cases, partly because, in a Bill now before Parliament, changes are proposed in the power and in the mode of procedure in respect of the judicial duties of the Council. The changes are, in principle, these two:—1. It is made certain in the Bill that the Council may remove from the Register for a fixed period the name of a practitioner whom it does not consider to deserve the extreme punishment of permanent civil disability, as such; whereas, as I have said, it has been held to be doubtful under the existing Act. 2. A power of appeal is granted against the decision of the Council to the High Court of Justice, in such manner as may be determined by rules of Court. These changes will, I doubt not, approve themselves to the Council. I mention them here because if, on the contrary, the long experience of the Council should seem to call for any modification in the proposed amendments in respect of an onerous office of peculiar delicacy imposed on us by Parliament, it would be clearly the duty of the Council to make such conclusion known to the Government, for the improvement of the clauses in question.

II. The next business to which your special attention is this year invited is the Report of your Committee on Unqualified Assistants, appended to which is a statement of the documentary evidence on which it is mainly based, with a letter from Dr. William Ogle, of the Registrar-General's office. This subject is closely connected with that of false death certificates, just now alluded to in the case of Gray. It is a many-sided question, affecting largely the health and well-being of the poor throughout the country, and one which has to be handled with great care. That grievous abuse exists cannot be doubted. The case of Mr. Gray, which has been alluded to, is, without any reasonable doubt, only one of many the particulars of which are never known. The statement which has been prepared by the Chairman of the Unqualified Assistants' Committee teems with evidence as to the relation which the habit of employing unregistered practitioners bears to the safety of the sick, to the education of medical students, and to the habits of a certain number of registered practitioners. It is easy to see that the three special subjects which come to-day before the Council in the ordinary discharge of its duties are closely connected. They will hereafter demand dispassionate inquiry and careful consideration with respect to the methods of instruction and the opportunities afforded in the several schools and hospitals both in this country and abroad in training young medical men. Persons well qualified to judge differ much as to the value, for the purpose of learning the practice of the profession, of apprenticeship, of residence with country practitioners, and of employing students in towns, either during their pupillage, or after it is ended. In one respect probably all will agree, that when pupils and teachers act with singleness of purpose for the real good of the sick, when the pupils have had a good previous education and are of exemplary personal character, when the masters and teachers are conscientious in the care they bestow alike on the pupils and on the patients, the best results for all three—teacher, pupil, and sick—may, and habitually do, follow. Anyone acquainted practically with the conscientious labour and benevolence of many teachers and students in the great cities of England, Scotland, and Ireland, knows that good untold is hourly done, and blessing poured on giver and receiver alike, by sending students among the sick poor. Witness, as examples, the well-known lives of Alison and Stokes, both when they were youths and when they were men. The subject, therefore, of employing "unqualified men" as assistants will have to be fully weighed before pronouncing against carefully directed

methods of employing students, on account of the misconduct of some few legally qualified practitioners. On the other hand, the Council will not be deterred from considering such changes in the law as the important letter from Dr. William Ogle seems to suggest.

III. Copies of the Report on Professional Examinations, drawn up by Professor Gairdner, Mr. Stokes, and Mr. Teale, together with the remarks of the bodies visited, and the resolution of the Council thereon, as directed by you, were sent by the Registrar to all the medical authorities and medical schools of the United Kingdom immediately after your last meeting. Under this third head I am led to observe that a considerable change of power is proposed in the Bill to which I just now referred, in respect of the teaching in the medical schools. By Clause 21 of the Bill it will be the duty of the Medical Boards in the three branches of the Kingdom to inquire into the sufficiency of the arrangements for teaching, by inspection or otherwise, in all recognised medical schools. It is impossible to exaggerate the importance of the provision contained in these few words. Those schools only will be recognised which reach the adopted standard of educational requirements; and those which do not reach it will cease to be recognised. It is well known to members of the Council that the opportunities are very different in different institutions, and that when once a so-called school is established it may attempt to teach over a range of subjects for which it has not adequate means, and which are better taught elsewhere. Small schools even undertake functions of scientific teaching which are best performed in the Universities. They may also profess to have the clinical opportunities which can only belong to hospitals that, either from size or situation, have large choice of varied and typical cases, or, as in Germany, have special relations to the municipalities. I venture to say that a combination of some Schools, like the combination of Colleges recently adopted in the University of Oxford, might be easily effected and be of the greatest service. The power of inquiry, distinctly given to the Medical Council by the new Bill, into the plant and method of schools, was held not to exist under the Medical Act of 1858. The Committee appointed last year to inquire into and report upon the deficiency of subjects for anatomical and surgical teaching and examination has not completed its inquiries. The subject of the Preliminary Examinations will be brought before you in a Report by a Committee appointed for the purpose at the last meeting. It is not without interest to note here that, in the Returns from the Army and the Navy Medical Departments, it appears that whereas in the year 1864, out of 49 candidates for the Navy, only 28 passed, and 21 failed, 16 being found deficient in anatomy, 4 in medicine, and 14 in surgery, none who went in for the examinations last year were found to be deficient in any subject; and whereas in the year 1864, out of 151 applicants for places in the medical department of the Army, 31 failed, 12 having failed in anatomy, 14 in surgery, and 23 in medicine, in 1882, 60 out of 69 candidates passed so as to qualify. Before quitting the subject of our educational arrangements, I had intended to have called to your notice some points connected with the conjoint scheme of examination, which, after many difficulties and much discussion, had been elaborated by all the licensing bodies in England; which received your sanction in 1877; and which has never come into operation—and then to have named other and more recent attempts made in the same direction. But circumstances have arisen which make it undesirable thus to occupy you on the present occasion—nor is this to be deplored—since, if the Bill, which is this day to be considered in Committee of the House of Lords, become law, all such agreements will be of no effect, and they will leave behind them nothing save the lessons of experience, and therefore of much labour, expended not wholly in vain. The Pharmacopœia Committee will present a report stating the steps which have been taken in the revision and preparation of a new edition of the Pharmacopœia.

IV. The Council will have noticed that allusion has been made more than once to the Medical Bill introduced into Parliament by the Government. Copies of the Bill were forwarded to me for the use of the Council. I therefore beg to be allowed to say a very few words, on presenting it to you, in relation to the progress of legislation in respect of the Department of Medicine. The disjointed and unsatisfactory state of medical education in the first half of this century had long baffled the endeavours of many honourable men who desired to remedy its defects. After years of discussion the present Council was formed in 1858. At least one great advantage immediately followed. Men who

were supposed to represent conflicting interests met together, and after a short time set themselves to the national task of securing a more uniform and better education for all medical students in each branch of the kingdom, of establishing uniformly wise and good examinations, which are the key to modern education, and of diminishing the number of the examining boards in the kingdom. Two Governments carried through the House of Lords Bills which would have completed these and other required improvements. A collateral issue as to the construction of the Council raised in 1871 obstructed further progress. In the Council and in the several licensing bodies any complete combination and any finality for examination arrangements have been paralysed by this question. For thirteen years students, teachers, examiners, and institutions have been hindered in the attempts they were making at securing in one way or another a sound, permanent, national standard for medical training. Those who have followed the progress of modern biology in all its branches, normal and abnormal, can alone estimate the evil of this suspense. It is quite sufficient to remind you of the names of Brodie, Green, the two Pagets, George Burrows, Thos. Watson, James Arnott, Cæsar Hawkins, Rolleston, the two Woods, Syme, Allen Thomson, Lister, Stokes, William Baly, Sharpey, Parkes, William Lawrence, Teale, Christison, Begbie, Hastings, Rumsey, to recall to your thoughts what a variety of force, what power of goodness, what devotion, what intellect, what public spirit, what self-sacrifice have been during the last twenty-five years thrown within this Council alone into the task of aiming to secure for the next generation, by improved medical education, the welfare of the sick, the health of the nation, the strength of our soldiers and sailors, the progress of natural knowledge, the higher general culture of the medical student, and the social position to be reached by all educated medical practitioners, without distinction of place or station. That great improvement has taken place in all these respects, no one who knows our medical students will for a moment question. But until the settlement of various disputed questions, which Parliament alone can settle, the Council is unable to ensure for either teachers or students the stability of any sound methods of education upon which agreement can be obtained. It remains for us, as I said last year, until Parliament see fit to relieve us from the labours imposed upon us twenty-five years ago, to continue to labour as faithfully and efficiently as circumstances permit, and, when relieved, to hand over to our successors such work as we have been able to accomplish for the public good, wishing them, with additional powers and the experience of the past, a hearty God speed. It is possible that this may be the last time that I shall be called upon to address you, except for the most formal business; and in this case I would wish my very last words to be the expression of gratitude for kindness accorded to me for twenty-five years from the whole Council, for support during nine years as your President, and to leave a record of strong personal affection to many whom I have for so long owed so much.

The following committees were then elected:—

Business.—Dr. Pitman (Chairman), Dr. Aquilla Smith, and Dr. Haldane.

Finance.—Dr. Quain (Chairman), Dr. Pitman, Dr. A. Smith, and Dr. Scott Orr.

On the motion of Dr. Pitman, a table showing result of examinations held in 1882, was received and entered on the minutes.

DR. AQUILLA SMITH pointed out the increased proportions of rejections shown in these tables as compared with former years, and which showed a vast increase in the severity of examination tests.

MR. MACNAMARA urged the importance of this subject, and thought the percentage referred to by Dr. Aquilla Smith ought to be entered on the minutes. The small number of rejections at the College of Physicians of Ireland was explained by the fact that candidates first passed the examinations of the College of Surgeons. The rejections at the latter were numerous. On the motion of Mr. Macnamara, percentage tables of this kind were directed to be prepared for publication with the tables, and covering the years 1879, 1880, 1881, and 1882, thus continuing the series already completed as far as 1878.

Various returns relating to examinations conducted by the Army and Navy and other bodies were received and entered on the minutes.

THE CASE OF MR. PROSSER.

The case of R. A. Prosser, whose conduct had been considered by the Branch Council was reported on to the following effect:—

"That the Branch Council, in accordance with the resolution of the General Council of July 6, 1882, having obtained the information contained in the statements relating to the case and considered these statements, and having also heard the opinion of the Solicitor to the Council, resolve that there are not grounds for finding Mr. Prosser guilty of infamous conduct in a professional respect."

To this Dr. Lyons moved an amendment, to the effect that Mr. Farrer, solicitor to the Council, be requested to attend the Council and state the grounds on which his opinion was based. Considerable discussion took place on this amendment, in which Mr. Simon, Prof. Humphry, Dr. Aquilla Smith, Mr. Macnamara, Prof. Turner, and the President joined. On a vote being taken the amendment was lost. Dr. A. Smith next moved an amendment to refer the report back to the Branch Council. Dr. Lyons seconded this amendment, which also proved the subject of discussion by several members of Council, and was eventually lost, when the original motion was carried by a considerable majority.

PETITION FOR RESTORATION TO REGISTER.

A petition was considered from George Stratten Symmons for restoration of his name to the Register, from which it had been erased in 1877. In connection with this case counsel's opinion was read, in which it was stated that the Medical Council had power to restore names erased from the Register. It was pointed out that the applicant sought to have only the L.S.A. restored to the Register, this qualification not having been taken from him by the corporation which granted it, notwithstanding, as was stated by Mr. Bradford, that the Apothecaries' Society was empowered to deprive licentiates of their qualification by the Act of 1874.

Dr. CHAMBERS moved that counsel's opinion, as read by the Registrar, should be entered on the minutes.

Dr. PYLE seconded the motion.

Dr. STORRAR opposed it on the ground that last year a similar course of action was strongly opposed by the solicitor to the Council.

The motion was lost.

Strangers were then requested to withdraw while the Council proceeded to consider the circumstances of the case before it, and as a result of the deliberations it was subsequently announced that "the Council do not feel that they would be justified in complying with the application. The qualification of M.R.C.S. Eng. formerly held by Benthon Puynter Morison having been taken from him by the College of Surgeons, the Council directed its erasure from the Register."

SECOND DAY.—FRIDAY, APRIL 20TH.

The first subject considered on the second day's meeting was that of a rejected medical practitioner named William Hoar, who was found guilty of adultery in 1882, the act having been committed under circumstances which brought the conduct of Mr. Hoar within the province of the Council as infamous conduct in a professional sense. Mr. Hoar having been summoned to attend before the Council, the latter body considered the matter, and resolved that Mr. Hoar had been guilty of conduct infamous in a professional sense, and directed the removal of his name from the Register.

THE CASE OF A. A. SADGROVE.

The next case was that of Mr. A. A. Sadgrove, who had been prosecuted in 1881 for having employed titles to which he could lay no claim. The facts are briefly as follows:—

Being appointed surgeon to a company, and possessing only the qualification L.A.H. Dublin, he made use of the titles L.R.C.P. Lond. and L.R.C.S. Edin., and was prose-

cuted and fined at the instance of the former body. There was a further suspicion that Mr. Sadgrove had exhibited a diploma of the Faculty of Physicians and Surgeons of Glasgow as proof of his being a licentiate of that corporation, but which, it was contended by the accused, was a Latin diploma of the "Knights of Malta," an order in Freemasonry, admittedly employed with a view to retaining his post. The similarity of this document with the diploma of the Faculty was insisted on by witnesses at the trial in 1881, and the Secretary to the Faculty testified to abstraction of such a diploma from the office in which they were preserved at the time Mr. Sadgrove was present as a candidate (unsuccessfully) in Glasgow.

The circumstances following on the exhibition of the document to the manager of the company were somewhat remarkable. This gentleman intimated to Mr. Sadgrove his intention to write to the Faculty on the day of his interview with him with the object of satisfying himself with regard to the genuineness of the document shown to him. A letter was written and posted on that day addressed to the Faculty of Physicians and Surgeons, Glasgow, inquiring whether Mr. Sadgrove held the licence of the Faculty. This letter never reached the Faculty, nor was it received by any person connected with the Faculty. Nevertheless, a letter in reply was in due course received by the manager of the company, having the printed heading "Faculty of Physicians and Surgeons, Glasgow," and purporting to be signed by Mr. Duncan, the Secretary of the Faculty, to the effect that Mr. Sadgrove was a licentiate of the Faculty and duly qualified to practise surgery. That letter was a forgery, and was not written by anyone connected with the business of the Faculty. The paper on which it was written, the heading, the handwriting, and the signature were of a kind foreign to anything known in the office of the Faculty.

In view of the above facts, and of others pointing in the same direction, the Council of the Faculty were of opinion that they would be chargeable with a dereliction of duty towards the public and the profession did they shrink, at whatever cost and with whatever result, from instituting a criminal prosecution against Mr. Sadgrove.

He was accordingly charged at the instance of the Faculty with forgery and fraud at common law. He was arrested in the office of the Secretary of the Faculty in Glasgow, on presenting himself a third time for examination, and was brought before the Justices of the Peace for the county of Berks at Wallingford, and was committed for trial at the Reading Assize. He was tried at those Assizes in January, 1882. A considerable part of the indictment was thrown out on technical grounds, and the verdict was one of acquittal.

The Branch Council for England having investigated the case, and being of opinion that though Mr. Sadgrove was acquitted of the charge of forgery and fraud, there are other circumstances in his conduct of which the General Medical Council can take cognisance, but in respect of which he is not amenable to a court of law, the Council proceeded to consider the case fully.

Mr. Sadgrove appeared in person before the Council in answer to a summons, and addressed it in his own defence, which was mainly that he had abstained from using any but his registered qualification after he had been served with a notice requiring him to do so from Somerset House, and which notice preceded his prosecution by the Faculty of Physicians and Surgeons of Glasgow. He further pleaded ignorance of the provisions of the Medical Act, and of the fact that he had incurred the penalties named in it. He concluded by making a direct appeal to the clemency of the Council, and submitted numerous testimonials as to character and conduct.

Dr. SCOTT ORR questioned Mr. Sadgrove on various points in connection with the circumstances under which he was prosecuted. He elicited that the accused had made use of the degree of M.D. which had been employed by his predecessor, but whether rightly or not, he was unable to state.

Mr. MACNAMARA asked for information concerning the

letter purporting to be from the Faculty of Physicians and Surgeons of Glasgow, and which stated that A. A. Sadgrove was a licentiate of the Faculty. Mr. Sadgrove said he had never seen the letter, but explained that, having mentioned the fact of his being unsuccessful at the examination for the licence of the Faculty to a Mr. Duncan, that gentleman wrote a letter which might have been the one referred to; but he could not further explain the matter.

Dr. LYONS asked if Mr. Sadgrove could offer any means of identifying the Mr. Duncan he referred to, and thus assist in explaining away the mystery, to which Mr. Sadgrove said he could give only the address in the letter received from this Mr. Duncan.

The Council then proceeded to deliberate on the case in private, and, strangers being readmitted, the following resolution was announced:—

"That the further consideration, in Mr. Sadgrove's case, of the subjects of the offence for which he had been summoned to appear, be adjourned till Tuesday, April 24, 1883, at 2 o'clock p.m., in order that he may have an opportunity of satisfying the Council as to the two following points:—

"(a) As to a letter of date September 10, 1881, stated to have been written by A. Duncan, Secretary to the Faculty of Physicians and Surgeons of Glasgow.

"(b) As to the allegation that he had falsely claimed to be a Licentiate of the Faculty of Physicians and Surgeons of Glasgow."

THIRD DAY.—SATURDAY, APRIL 21ST.

UNQUALIFIED ASSISTANTS.

Dr. CHAMBERS moved the first resolution appended to the report of the committee on unqualified assistants as follows:—

"That the Council ask for legislation to the effect that any registered practitioner, practising for gain, who knowingly and wilfully deposes a person not registered or qualified to be registered under the Medical Act, to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person, shall be subject to the same legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner: but with a special proviso that such enactment shall not hinder any duly regulated training of pupils by qualified teachers, nor any legitimate action of nurses, midwives, or dispensers."

And in doing so took the opportunity to explain the scope and object of the inquiry on which the committee had been engaged. It had included consideration of the uses and abuses of the system, and the committee speedily discovered that numerous classes of unqualified assistants existed. There were actual students *in statu pupillari* under the direction of a practitioner, receiving no salary, or even paying a premium. Another class was that of actual salaried assistants who helped their employers by performing small acts of professional practice, but in no case acting other than as subject to their master. A third class saw and treated patients entirely on their own responsibility, calling in the employer as a sort of consultant in serious cases. A fourth class employed the qualified man as a "cover" for their operations, and paid him for the service. The committee had considered these various classes of unqualified assistants in their report; the educational question had been considered also; the committee believed that, as a rule, due amount of supervision was maintained by the qualified master, but still cases did occur which showed the necessity for careful consideration. The committee had not thought it right or politic to interfere with the ministerial functions of pupils, but only with the question of deputation of responsibility by men qualified to unqualified assistants.

Mr. SIMON seconded the resolution.

Dr. AQUILLA SMITH moved an amendment to substitute "practitioners" for teachers at the end of the resolution.

Dr. COLLINS spoke as one who had experience of apprentices and assistants. He thought the terms of the resolution too stringent, and that they would apply unjustly to many practitioners who legitimately employed pupil assistants. The resolution ought not in any case to come into law immediately, but time should be allowed for substitution of properly qualified for unqualified assistants. He said that the plan of sending students from hospitals to midwifery cases without previous experience was itself an abuse as bad as that of employing unqualified assistants.

Mr. SIMON moved that the Council go into committee on the report; which being seconded and carried, he proceeded to explain that the committee had no intention of interfering with any legitimate employment of unqualified men, but to draw the line at *deputing* such assistants to take charge of important cases.

Dr. AQUILLA SMITH thought ample precautions had been taken to legitimise the purely ministerial duties of unqualified assistants.

Dr. PITMAN asked if the Apothecaries' Society did not grant certificates to assistants to apothecaries? Would these persons be punishable under the suggested rules, or would they be regarded as qualified.

Mr. BRADFORD said the Act of 1815 imposed the duty of licensing assistants to apothecaries as dispensers and compounders of medicine only, and not as practitioners of medicine. They possess legal status as assistants.

Mr. MACNAMARA felt with Dr. Collins the proposal that of the committee was very stringent. It was very important to repress the abuses of the system, but the clause as it stood might be misconstrued, and he would move the introduction of these words in the resolution: "And the partial employment of such in the treatment of the sick under the direct supervision of a duly registered practitioner."

Dr. COLLINS seconded the amendment.

Mr. TURNER felt that it was due to the committee to express admiration at the thoroughness and excellence of the report. He felt, however, that the resolution under discussion required careful consideration. There were two classes of assistants, viz., those who were apprentices receiving instruction, and possibly paying for it, and others who gave their services in return for a salary. It might be necessary to put these two classes on different footings. Mr. Macnamara's amendment covered the distinction. He felt that amongst the poor, unqualified assistants might be indispensable. He referred to the wholesale manner in which "medical herbalists" granted certificates of illness which were accepted as valid by societies and companies knowingly, as shown in the evidence given before the Royal Commission. If the Council increased the difficulty of employing unqualified assistants it would force the artisan classes more and more into the hands of "herbalists," and so do an injury to the sick poor.

Dr. STORRAE urged the case of country practitioners whose practice extended over large areas, and who employed an unqualified assistant, and in whose absence the latter might easily be called on to act in a position of responsibility on an emergency. To deny him this right would be to take from him privileges conceded to the chemist and druggist. Herbalists did not confine their practice to the poor. In 1857 a member of Parliament had told him that he himself was under treatment by a herbalist. Dr. Storrae wished to see the power of retaining the services of duly qualified students and pupils reserved to practitioners.

Mr. SIMON insisted that the committee had been most anxious to act fairly in both interests concerned, and pointed out the difficulties under which its labour had been carried out. He suggested to add after "such enactment" the words "shall not hinder any duly regulated education of students in medical schools or otherwise by legally qualified practitioners, nor the use of trained pupils in partially treating the sick under the direction and responsibility of such qualified practitioner, nor any

legitimate employment of nurses, midwives, or dispensers."

Mr. MACNAMARA withdrew his amendment.

Dr. HALDANE said that the system was unknown in Scotland.

Dr. AQUILA SMITH contended that any inconvenience arising from adoption of the resolution would be experienced only by those who were undeserving of being considered. There was no lack of duly qualified men to take the place of unqualified assistants. He supported the resolution.

Prof. HUMPHRY expressed the assistance he had derived from his own pupils at various times. The introduction of a Bill like that pressed for would do much to make medical practice more difficult. Substitution of young qualified for old unqualified assistants would cause much inconvenience and mischief, because it would intensify the difficulty of country practice. Such a measure should be introduced most carefully, and not suddenly. Something was required to be done in the way suggested, but the manner of doing it was not easy to determine. As a rule, qualified young men were much less fit for practice than experienced unqualified men. It would be desirable to acquaint young men with the conduct of practice before qualification.

Mr. SIMON said the committee had given careful consideration to the question of inconvenience arising from loss of unqualified assistance, but, as the report stated, it was not deserving of the importance given to it.

Dr. CHAMBERS was of opinion that the inconvenience alluded to would be only of a passing kind, and would be followed by advantages of an important description.

The PRESIDENT expressed his sense of the sterling value and importance of the report, which was on a subject of the utmost gravity, and was evidently so regarded by the Council.

The amended resolution was then put and carried.

The second resolution, to the effect

"That communications be entered into by the Council with the Registrar-General with the view of procuring such amendments of the Registration Act as will diminish the present frequent evasions of the Registration Act in the certification of causes of death."

was then moved by Dr. Chambers and seconded by Mr. Simon.

A letter from Dr. Ogle was read, in which the writer severely criticised the action of the Medical Council in omitting to deal severely with cases of infamous conduct, and repudiating the charge that the Registration Office encouraged violation of the Registration Act by its unwillingness to prosecute.

Dr. LYONS believed the present mode of registering deaths could never be made perfectly satisfactory. Some better plan needed to be devised. By throwing the duty of stating the cause of death on practitioners they were called on to perform a task that was oftener than not almost impossible. Dr. Lyons recommended adoption of the French plan of registering deaths by agency of a special officer, who ascertains that death has occurred, and learns from the attending physician what was its cause.

The motion was then put and carried.

Dr. CHAMBERS next moved :—

"That the Council record on its minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants, and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract, are, if brought before the Council, regarded by the Council as charges of infamous conduct under the Medical Act."

Dr. Chambers pointed out that the Council had already so stigmatised this conduct, but it should be more generally known that this was so.

The resolution was carried.

The Council having then resumed, the resolutions, as

endorsed in committee, were submitted severally, voted on, and carried.

PRELIMINARY EXAMINATIONS.

A committee appointed in July, 1882, to consider and report on the list of bodies whose examinations in general education are recognised by the Council, presented a report, in which it was recommended that all but four of these examinations should be retained. The report was adopted.

From this it will be seen that two examinations in medical colleges of Michigan and Halifax, Nova Scotia, had been struck off as a result of the committee's work.

The resolution was carried.

THE PHARMACOPŒIA.

A report presented by the Pharmacopœia committee, appointed July 8, 1882, was read and received, but discussion on it deferred.

ERASURE FROM REGISTER.

On the motion of Mr. Macnamara, seconded by Dr. Collins, the name of Robert Gray, L.R.C.P.I., was removed from the Register.

DENTAL BUSINESS.

A table showing results of professional examinations held in 1882 for qualifications under the Dentists' Act, was received and entered on the minutes.

WEDNESDAY, APRIL 25, 1883.

THE GENERAL MEDICAL COUNCIL.

On Thursday last commenced what many persons feign to believe will be the last session of the General Medical Council; and the feeling of approaching dissolution might almost be considered to have tinged the reflections of the members who have so far joined in the

deliberations of the assembly. With every desire to think kindly and sympathetically of a body situated in the delicate position the Council occupies at present, we are nevertheless compelled to utter the opinion that its latest achievements are but a degree less somnolent than its previous performances. It is, perhaps, a little unfortunate that at this time, of all occasions, peculiar opportunities should have presented for the exhibition of that sleepy legislation which has been reduced to a species of fine art by the efforts of the Council; but so, at any rate, it is. Immediately following after the delivery of Dr. Acland's Presidential Address, and the despatch of certain formal business, the Council proceeded to consider a report sent to it from the English Branch Council, which concluded with a resolution to the effect that there were not grounds for considering a certain member of the profession had been guilty of infamous conduct in a professional sense. It should be understood that the General Council had remitted to the Branch the duty of carefully and fully considering all the details connected with the case, with the desire, presumably, of saving time which must otherwise have been devoted to it by the whole assembly. To an ordinary understanding this course presents the appearance of being reasonable and proper; and it would have been supposed that in due time the report as presented would have been received as final. Not so, however, did certain members of the Council view the matter; and a very considerable amount of time was occupied by them in prosecuting an endeavour—first, to force a full consideration of the whole affair by the Council in the face of its own mandate to the Branch assembly; and on this failing, secondly, to have the matter referred back again to the Branch Council. These proposals were too openly obstructive to secure a majority in their support, even in the General Medical Council, which accordingly, after much valuable time had been thus foolishly wasted, agreed to the original motion.

Then came one of those private entertainments indulged in by the Council whenever opportunity presents, and from participation in which "strangers" are excluded, to the end that the Council may secretly deliberate and lengthily in the judicial capacity which so mightily pleases many of its members. Practically, this concluded the business of the first day, with the exception of a little more formality in the way of reading and receiving reports and letters. The second day offered even less of interest to report. Commencing with the familiar direction that "strangers should withdraw," a long discussion ensued on the case of a registered practitioner who, as co-respondent in a divorce suit last year, was adjudged guilty of adultery and condemned to pay damages amounting of £5,500. The facts of the case admit of no extenuation or mitigation as regards the defendant, who had, if anyone ever has, forfeited all title to professional respect. Apparently, however, there was something connected with it which public trial had failed to elicit, and on which the Council found it necessary to expend about ninety minutes of time before deciding to erase the offender's name from the *Medical Register*.

The next business was similar in kind to that already transacted, and comprised consideration of the case of a practitioner who, two years ago, was charged with using certain qualifications to which he was not entitled, and further, with having falsely issued a diploma of the Faculty of Glasgow. After hearing the accused in his own defence, the Council again entered into secret discussion; and after a long interval the public were informed that further consideration of the case would be deferred till Tuesday. This concluded the second day's business, with the exception that the report of the committee on unqualified assistants was received and ordered to be entered on the minutes.

We have been thus particular in dwelling on the indefensible waste of time indulged in by the Council when acting in a judicial capacity, because at this moment its most recent action may properly serve to point the weaknesses which distinguish it. It is not too much to say that, with the exception of the time occupied in delivery of Dr. Acland's opening speech, less than half-an-hour out of the nine hours nearly over which the first two days' sittings extended, was spent in discussing legitimate business. It seems intolerable that such flagrant waste of time should be indulged in as was exhibited on these two occasions; but even were a special judicial committee of the Council empowered to consider and report on such cases as are above referred to, there is too good reason for assuming that strenuous attempts to nullify the saving thereby effected would emanate from at least a section of the Council.

Not before Saturday was any beginning with actual business of interest to others than those immediately concerned, as judges and criminals, made. On that day the first agenda proceeded with was the report of the Committee on Unqualified Assistants; and in connection with it a long and, in many respects, instructive discussion ensued. With the report itself we shall have occasion to deal at greater length subsequently, especially as it embodies the information given in a series of articles published in our columns last year, and arrives at exactly the conclusions there insisted on.

It was not, of course, to be expected that the Council would give unhesitating acceptance to a resolution couched in such terms as the following:—"That the Council ask for legislation to the effect that any registered practitioner, practising for gain, who knowingly and wilfully deposes a person not registered or qualified to be registered under the Medical Act, to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person, shall be subject to the same legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner: but with special proviso that such enactment shall not hinder any duly regulated training of pupils by qualified teachers, nor any legitimate action of nurses, midwives, or dispensers." The modification, however, which this underwent ere finally being accepted, does not deprive it materially of the power it will possess to reduce a vast and serious evil, and one which it is passing strange to find that such acute observers as Professors Turner and Humphry should regard almost in

the spirit of apologists. Perhaps the most remarkable incident in connection with the debate, however, is the fact that a member of the Council—Dr. Chambers—should have pointed out, by implication, the farcical nature of the Council's action in first stigmatising certain conduct as infamous, and then at once forgiving the delinquent. This, it will be remembered, occurred last year in the case of an East-end practitioner; and it is now more an excellent joke than any real evidence of wisdom that the Committee on unqualified assistants advises the Council to record on its minutes, *for the information of all whom it may concern*, that it will regard such conduct as it has called infamous in the past as infamous in the future also. This, in effect, is all that the third resolution of the Committee amounts to, and its influence in staying improper proceedings will be *nil*, even when supported by the other resolutions, until the Council endows its decisions with a backbone that will not give way the moment its strength is tested.

This matter of unqualified assistants, however, will demand further consideration from us; but we may at once record our sense of the carefulness and thoroughness which characterises the report, the preparation and execution of which reflect the utmost credit on the Committee, and especially on its accomplished chairman, Dr. Thomas King Chambers.

CLAIMS FOR PRIORITY IN OBSERVATION AND IN THE INTRODUCTION OF NEW METHODS OF TREATMENT.

FROM time to time unseemly wrangles appear in the columns of our medical journals in connection with the claim to priority in bringing forward what is regarded as a new observation or a new method of treatment. That such should be the case is a matter of regret, and springs from the ungenerous side of our nature on the one hand, and a want of true largeness of spirit, and of wisdom, on the other. The one desires to belittle another's efforts, taking pride in displaying the extent of his own reading; the other should certainly not allow himself to be disturbed or put out by the fact that what to him is new has been known before. That such should be the case does not rob him of the credit of originality, as far as he is concerned, since his conclusions are the result of original observation and thought, on his own part, and to him are a fresh departure. Indeed, there is no reason why he should not welcome the proof, that to others had occurred the same idea as to himself. That two men should arrive independently at certain conclusions is more or less evidence of the truth of those conclusions, or, at least, lends additional colour to the likelihood of their being true, and in so doing tends to heighten the value of the observations made or conclusions arrived at. It is true that the longer we live the more clearly we find that those who have gone before us have been acute observers and close thinkers, fertile in therapeutic resource, and careful in watching and recording the results of the remedies employed, or the methods of treatment adopted by them in their medical and surgical management of the cases under their care.

Modifying the old adage, we may safely say that much that is true is not new, and much that is new is not true. *What is true*, and occurs to one man as the result of original observation and thought, may just as well occur to many; and the credit of the observation is just as great for all as for one, provided the work is original; *in that alone lies the credit*. There is good reason why old truths should be rediscovered as new ones. The opportunities and scope for the clinical study of disease is limited to the human body itself; therefore the same problems which are presented to us now were presented in the days gone by to eyes and minds of highly cultivated men, and men who were thoroughly accustomed to the close observation of symptoms and the effects of remedies, since they were not acquainted with the various methods of physical examination that are now in every-day use, and are looked upon as almost essential to the proper study and treatment of disease. The study of symptoms and of therapeutics, and the knowledge of *materia medica*, was almost greater in former days than it is at present. Many methods of treatment were initiated in those days which were sound in principle, but which were greatly abused in practice, and the effects of which were explained manifestly upon false grounds, when brought to the test of advancing knowledge of physiology, in the study of which the last half century has seen such immense strides. Erroneous explanation of their *modus operandi* and abuse led to their disuse, and finally they sank into obscurity, and practically became unknown. Here and there the fact that such methods had been in use is known; but the knowledge is confined to the few, and the practice is ignored by all until once more brought to light as the result of clinical observation and research by a new worker in the same field. Empirically the idea itself has been found true, though wanting the additional force and support of a scientific explanation, that possibly increased knowledge of the laws of life may be able to give it.

Again, there is at all times a decided tendency to fashion in the treatment of disease—*vide* the changes that have taken place in the various forms of stimulants recommended; now port, then sherry, then claret, then whisky and water, and so on through the whole range, of hocks, burgundies, sparkling wines, beer, porter, brandy, gin, &c. Again, we recall to mind venesection, leeching, blistering, moxas, issues, the use of mercury, iodide of potassium, salicylates, and a host of remedies, every one of which are in themselves most useful when used with proper discrimination and judgment, but which, each and all, have had their day of popularity, until brought into disrepute by being used without judgment, and, one may say, as a matter of routine in the treatment of cases for which they were altogether inapplicable. Even in the present day there is a wide and general abuse of the drug quinine, which is frequently prescribed by men who never take into consideration the fact that it is not always the most suitable tonic that can be given.

Of making books there is no end. Work succeeds work, edition follows edition; the works of the past are shoved almost out of existence by those of the present.

Those who are busily engaged in active practice find it hard to keep abreast of the work of the present day, and would certainly find it almost impossible to dip deeply into the literature of the past, or possibly may not have even the opportunity for doing so; he would be indeed a remarkably clever man whose knowledge of the literature of his profession embraced all that has been written concerning disease and its treatment; it is not wonderful, then, that much ignorance of past methods of treatment should prevail, or that old ideas should be again brought forward as new truths by those who may fairly claim to be original workers in the practice of their profession. All generous minds will take pleasure in encouraging those who think they have discovered something new; whilst among the latter, all who are truly wise and large-hearted will not grudge the credit due to those who have gone before, even if the idea in question has been only dimly shadowed forth, rather than seen clearly, as it may be, in their own case.

To have the credit for original work is a laudable ambition enough, but at the same time it is not free from the taint of selfishness and self-seeking; the highest and most laudable form of ambition is to have at heart the true interests of the profession; to seek after truth for truth's own sake, and for the benefits it may confer upon suffering humanity; to put away small jealousies, and to encourage those who are earnestly making the most of their opportunities to relieve suffering and cure disease; and to be careful at all times to promote union and kindly feeling amongst the members generally of our noble profession. The kind and encouraging word is as easy to give as the bitter criticism and sneer: it ought to be the earnest desire of all to give it, when at all possible to do so. Unity and good feeling amongst the members of the profession will lead to increased respect and an improved position in the eyes of the world at large. Dissension and bitterness have an entirely opposite effect.

Notes on Current Topics.

Retrogression.

ON Friday evening the House of Commons, by a majority of 72 out of 292 votes, expressed agreement with a motion introduced by Mr. Stansfeld, to the effect "That this House disapproves of the compulsory examination of women under the Contagious Diseases Act." It is, of course, impossible to ignore that in this the Anti-Contagious Diseases Association has scored an important victory, or to be oblivious of the fact that a direct and necessary consequence of the vote must be to reduce the Act to the position of a meaningless and valueless statute. The Government assisted the result arrived at in a great measure by treating the question as an open one, and in the debate which ensued on Mr. Stansfeld's proposition the most striking feature was the exhibition of disagreement afforded by speeches from members of the Cabinet. Mr. Osborne Morgan and Lord Hartington supported the Acts as they were, but Mr. Childers, while admitting their efficacy, proof of which was too strong to enable him to vote for their repeal, was nevertheless con-

vinced that compulsory examination was not an essential part of their administration. He accordingly voted for Mr. Stansfeld's motion. The attitude of the Government towards the whole question was not inappropriately characterised by Sir Stafford Northcote, who regarded it as "most feeble;" it will, however, be incumbent on it now to pursue some definite course of action in response to what has all the value and force of a mandate from the House, and some curiosity will be felt to know exactly what form of proceeding will be adopted in the emergency. In reply to Lord Randolph Churchill, Lord Hartington said he was unable on Friday to state how the Government would act; and even at a later period there will be some difficulty in the matter after the evident signs of inharmonious relations between the members of the Cabinet already apparent. For the present, it must be accepted that the reign of unchecked contagion is about to recommence in the Forces; for any check to infection consequent on voluntary submission to examination on the part of women it is hopeless to anticipate.

Mr. Spencer Wells.

UNIVERSAL satisfaction will be felt at the announcement that Her Majesty the Queen has been pleased to grant the dignity of a baronetcy to the President of the Royal College of Surgeons of England, Mr. T. Spencer Wells, "in acknowledgment of the distinguished services he has rendered to suffering humanity by a life-long devotion to the duties of his profession." Though such a distinction might have been offered with more gracefulness at the time when moneyed claims to consideration swayed the distribution of titular honours to the exclusion of scientific worth, still it is satisfactory to find that even now the Government is awakening to a long-neglected duty; and, with the exception of Mr. Lister, there is no living surgeon more deserving than Mr. Spencer Wells of having recognition paid to the advantages conferred on humanity by the exercise of his skill and knowledge. Perhaps it may not be entertaining too sanguine a view of returning appreciation of worth on the part of our rulers, to anticipate that the time is approaching when scientific and intellectual eminence shall be held of equal importance with the faculty of money-making, and shall exert as weighty a claim to especial reward. The roll of names distinguished by titular honours in this country has hitherto been singularly deficient in those of persons whose eminence in the profession of medicine has been consequent on the performance of labours having for their result preservation of life and amelioration of suffering to an extent wholly incalculable.

The London College of Physicians and the Bill.

THE committee appointed to examine and report on the new Bill on behalf of the College of Physicians of London, has done its work and presented its report, which is mainly drawn up in the interests of the Colleges of Physicians and Surgeons, and contains little to excite comment or criticism.

The Conjoint Examination Scheme.

THE scheme entered into between the two Colleges of Physicians and Surgeons in London has apparently met the fate we predicted for it in these columns, and has been abandoned even by its inventors. This, at any rate, is the only construction possible to be placed upon the action of Mr. Marshall, who, when the time for discussing his motion in the General Medical Council on Thursday arrived, announced that he had no intention of proceeding with it. This motion was couched in the following terms:—

“That the proposal of the Royal College of Physicians of London and the Royal College of Surgeons of England to unite or co-operate, under clause 19 of the Medical Act, in conducting the examinations required for the qualifications of Licentiate of the Royal College of Physicians of London and Member of the Royal College of Surgeons of England, be sanctioned by the General Medical Council.”

There were not wanting signs that the matter would have excited criticism, however, for Dr. Quain had given notice of a motion to the effect—

“That when the proposal of the Royal College of Physicians of London and the Royal College of Surgeons of England to unite or co-operate, under section 19 of the Medical Act (1858), comes before the Council for its sanction, he will ask certain questions in relation thereto.”

In consequence, however, of the withdrawal of Mr. Marshall's resolution, that standing in Dr. Quain's name naturally fell through also; and there the matter ended, except that a deputation from Owens College, headed by Dr. Arthur Gamgee, which was to have attended the Council on Saturday morning in reference to the same question, did not appear, the cause for its doing so having been thus removed. It is to be hoped this is the last we shall hear of a proposal as unwise as it was unwarrantable and ill-conceived.

The Quacks' Clauses of the Medical Bill.

THESE clauses, which, as we have already said, do not profess to be directed against the illegitimate practice of medicine and surgery, and which prohibit nothing except fraudulent assumption of medical titles, are—in this respect—the worst part of the Bill. In the passing of the measure through committee in the Lords the following change was made in clause 28, which will now be worded as follows: “If any person, whether a registered medical practitioner or not, *who practises for gain, or professes to practise, or publishes his name as practising medicine or surgery, or receives any payment for practising medicine or surgery,* takes or uses a medical title which by this Act is not permitted to be entered on the Register, he shall, on summary conviction, be liable to a penalty not exceeding £20.” By the amendment the italicised words were added. The object and effect of this addition has been misconceived by the *British Medical Journal*. It was not intended to enlarge or strengthen the clause, but rather the contrary, for it confines the operation of the law to those who practise “for gain.” In other words, it allows anyone to use an unregistered and unregistrable title if he does not practise to earn money by it, and is no doubt intended to allow holders of an unregistrable title to use it if they are not in active practice as a means of livelihood.

Notification of Infectious Diseases.

A SPECIAL meeting of the Metropolitan Counties Branch of the British Medical Association was held on Tuesday last, to consider Mr. Hastings' Bill for the Compulsory Notification of Infectious Diseases. The subject occupied the greater part of the time of the meeting. Dr. W. Carter, of Liverpool, whose labours in regard to the subject are well known, was present by invitation, and, in an able speech of nearly an hour's duration, pointed out the objections to enforcing on medical men the public notification of cases of infectious disease occurring in the course of their practice. Remarks were also made by the President, Mr. Sibley, Dr. E. H. Vinen, Mr. Nelson Hardy, Mr. Ernest Hart, Dr. Hare, and other members; and, finally, the meeting authorised the President to append his name, on behalf of the Branch, to a petition against Mr. Hastings' Bill, based on that adopted by the Parliamentary Bills Committee of the Association.

At the annual general meeting of the North-Western Association of the Medical Officers of Health, held on the 12th inst., Dr. J. M. Fox, who was elected president for the ensuing year, speaking of the official position of medical officers of health, objected to the attitude of the Local Government Board with regard to the notification of infectious diseases as unwise. He said that it was not necessary to import the medical attendant into the question at all, and suggested the desirability of enlarging the functions of officers already existing, such as those of the registrars of births, deaths, and marriages, and the relieving officers, rather than the creation of fresh machinery.

The Election of Examiners in the Irish College of Surgeons.

THE annual election will take place, in accordance with the Charter, on the first Tuesday in May, *i.e.*, next Tuesday, and will be conducted by seven chosen by lot from amongst the twenty-one Members of Council. Mr. H. G. Croly, surgeon to the City of Dublin Hospital, has resigned his seat at the College Council in order to seek an examinership, and we understand that Mr. Kilgariff, of the Mater Misericordiæ Hospital, Dr. Lambert Ormsby, of the Meath Hospital, and Dr. Kendal Franks, of the Adelaide, will also be candidates. Should the Medical Bill pass, the functions of the collegiate courts of examiners will be somewhat reduced in extent; but, as the primary examinations of the College will still be held, it will be necessary to maintain the same number of examiners as at present.

Twelfth Congress of the German Society for Surgery.

THIS Congress was held in Berlin from the 4th to the 7th of the present month. Its president was, as usual, Herr von Langenbeck, who has filled this office from the institution of the society. As usual, also, some of the more distinguished foreign members had the honour of being presented to the German Emperor. Those upon whom this mark of distinction was conferred were Herrs Thiersch, Schoenborn, Maas, Roth, and Gussenbauer.

The Tubercle-bacilli War in Germany.

WHAT is called the tubercle-bacilli war,¹ and to which we devoted a leading article a fortnight since, still rages in Germany; but as the position and importance of the micro-organism in the realm of medicine will not be decided by a paper warfare, it is scarcely necessary to follow it through all its stages. It matters little to us whether the victory falls to the lot of Vienna or Berlin, but it does matter that whenever gained it shall be decisive, and we watch with intense interest the experimental researches now being carried on by the rival schools, and shall not fail to keep our readers *au courant* with the results.

The Liverpool Infirmary for Children.

A NEW departure in hospital management has been signalled by the action of the medical board of this institution last week in carrying the following resolution:—"That the members of the medical board now present, learning that Dr. Oxley's term of office as Physician to this institution is about to expire, and being unwilling altogether to lose him as an active colleague, hereby beg to suggest to the committee that, when in accordance with rule 23, Dr. Oxley becomes Honorary Consulting Physician, the trustees be invited to sanction the committee's placing six beds in the institution under Dr. Oxley's care." This resolution has, we learn on undoubted authority, been endorsed by the managing committee, and for the first time in hospital management a consultant is to have beds as though he were a member of the active staff. Something will undoubtedly be said against the general adoption of such a practice, as opposed to the legitimate aspirations of the junior members of a staff; but as in the present instance the step was taken at the earnest request of the medical board itself, no possible objection can be entertained, and the hospital will be all the stronger by the retention of so valued a member on its executive.

Medical Charity.

At a quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men, held a few days since, Dr. Pitman, V.P., in the chair, applications were read from 58 widows, 5 orphans, and 3 orphans on the Copeland Fund, and the sum of £1,227 was recommended to be distributed among them in July next. The death of a widow was announced whose first grant had been made in 1857, and who had received a total of £1,056 10s. from the Society. Another widow no longer required assistance. Three new members were elected. It was resolved that the following gentlemen should be recommended for election at the annual general meeting, as officers to supply the vacancies occurring—viz., Dr. George Johnson as Vice-President, in the place of Sir Thomas Watson, deceased; Mr. Cooper Forster, Mr. Garman, Dr. Garrod, Dr. Grigg, Mr. Freeman, and Mr. Warrington Haward to be directors in place of the six senior directors who retire. It was also resolved that Mr. J. R. Upton, honorary solicitor, and Mr. John Croft, F.R.C.S., a benefactor, be recommended for election as honorary members. Legacies to the amount of £280 were reported as having been received since the commencement of the present year; £200, less duty, from Mr. Henry

Sterry, V.P.; and £100 from Mrs. Allnutt, part of a sum left by Dr. Allnutt, her late husband, for charitable purposes.

A Resuscitated Medical Society.

THE Medical Society of Wigan having died out some time since for want of adequate support, a determined effort by the profession throughout the district has resulted in its re-establishment, and last week the first general meeting was held in the Mechanics' Hall, when the following office-bearers for the ensuing year were elected: Mr. W. Croudson Barnish, president; Mr. Elisha H. Monks, vice-president; and Mr. R. Prosser White, hon. sec. and treasurer. An alteration in the time of meeting and amount of subscription having been passed, the President gave an address upon "Recent Advances in Scientific Medicine." Two papers were read by Dr. Webster, on "Double Apical Pneumonia," and the other, "Excision of the Knee." Microscopical specimens of bacilli were exhibited by Mr. Barnish. Mr. Jackson showed a recent preparation of traumatic perforation of the orbital plate of the frontal bone. The following members were present: Messrs. Barnish, Monks, Williams, Webster, Brady-Withington, Jackson, Berry, Wood, White, E. H. Monks, Shepherd, W. M. Boocroft, and R. P. White. Wigan is an important town of a hundred thousand inhabitants, with about thirty medical men, besides those in surrounding districts, and should certainly be in a position to support a local society. We counsel cohesion, and success will be assured.

WE understand that H.R.H. the Prince of Wales has consented to preside at the anniversary festival of the Royal Hospital for Diseases of the Chest on June 1st.

HER Royal Highness the Princess Christian has consented to open the new wing of the North-West London Hospital some time in June.

THE action of Convocation of the University of London, in electing Sir James Paget as Vice-Chancellor of the University in the place of the late Sir George Jessel, will give great satisfaction to the profession.

THE Governors of the Sheffield General Infirmary have just received the magnificent contribution of £10,000 from Mrs. Overend, of that town. The interest of the gift is to be devoted to sending convalescent patients to homes at the seaside or elsewhere.

SOME sensation has been caused at St. Petersburg by the announcement of Professor Sorokin, in the course of one of his lectures at the Medico-Surgical Academy, that, judging by certain signs which he had noticed in several bodies lately examined, there was the possibility of cholera appearing in Russia during the present year.

JUDGMENT has at length been given in the Appeal Court of the Queen's Bench in favour of Abrath, in the case of Abrath *versus* the North-Eastern Railway Company on the ground of misdirection by the judge. A new trial will now take place, in accordance with their lord-

ships' opinion that the verdict was against the weight of evidence.

We regret to announce the very serious illness of Dr. B. Wills Richardson, of Dublin, Chairman of the Court of Surgical Examiners in the Royal College of Surgeons in Ireland, and Senior Surgeon of the Adelaide Hospital, Dublin. Dr. Richardson is, we understand, suffering from alarming cardiac symptoms, and has been ill since Saturday, the 14th.

We are asked by Dr. Ludwig Loewe, of Berlin, to announce as a matter of interest to members of the profession who propose to visit the Berlin Hygienical Exhibition that the Berlin Polyclinical Institution, in which clinical lectures on otology, rhinoscopy, dermatology, syphilography, laryngology, neuropathology, electrotherapy, ophthalmology, &c., are given daily, will be open to them during the said Exhibition.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Bristol, 16; Leicester 18; Newcastle-on-Tyne 19; Derby, Plymouth 20; Edinburgh, Bolton, Bradford 21; Wolverhampton, Portsmouth 22; London, Brighton, Cardiff, Norwich, Salford, Birmingham 23; Birkenhead, Nottingham, Sunderland, Oldham 25; Sheffield, Halifax 26; Huddersfield, 27; Leeds, Preston 28; Liverpool, Manchester 30; Dublin 32; Glasgow, Blackburn 33; Hull 34.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were—From whooping-cough, 2·8 in Plymouth, and 4·7 in Hull; from scarlet fever, 2·1 in Leeds and 2·5 in Sheffield; from measles, 1·2 in Sheffield, and 1·6 in Liverpool; and from "fever," 1·4 in Blackburn. The 36 deaths from diphtheria included 20 in London, 7 in Glasgow, 3 in Liverpool, 2 in Edinburgh, and 2 in Birmingham. Small-pox caused 2 deaths in London, one in Leeds, and one in Sunderland, but not one in any of the other towns.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE GLASGOW MEDICO-CHIRURGICAL SOCIETY AND THE UNIVERSITY.—Judging by the letters which appear at present in the Glasgow daily newspapers, touching medical matters, there must be some highly inflammatory compound in the atmosphere. Dr. Gairdner, as chairman of the meeting which we reported in our last, wrote a letter to the *Herald* explaining the anomalous position which he then occupied, and animadverting somewhat on Dr. MacVail for certain of his statements. Dr. MacVail replied, and a rejoinder comes from Dr. Gairdner the terms of which, considering that want of gentlemanly courtesy has certainly not hitherto been imputed to him, surprise us not a little. *Inter alia*, Dr. Gairdner says, "It is of no use arguing reasonably with Dr. MacVail, so with an apology to your readers for occupying so much of your space, I have done." Had the learned and usually courteous Professor acted on this intention the matter would not have been so bad, but he

unfortunately added the following rider:—"I have every disposition to think well of Dr. MacVail, and have never once failed, as he knows very well, in respect for him, whether in private or in public; but when he makes a grievance, and once again constructs a base imputation out of the undoubted fact that the academic element in Glasgow did not rush to his meeting and reply to and demolish his wild and reckless speech 'then and there,' I must take the liberty of pointing out to him that there are reasons why gentlemen, not to speak of professors, do not choose to run-a-muck of every passing chimney-sweep in the streets, much less at a public meeting." Such is the analogy which "a gentleman, not to speak of a professor," unfortunately permits himself to employ in criticising the opinions, upon highly important public questions, of a professional brother. We frankly admit that it is not often that any fault of this description is chargeable against Professor Gairdner, and consequently the transgression is all the more remarkable and regrettable.

GLASGOW SOUTHERN MEDICAL SOCIETY AND THE MEDICAL ACTS BILL.—At a meeting of the Glasgow Southern Medical Society, held on the 19th inst., the following resolutions against the Medical Acts Amendment Bill were unanimously adopted:—(1.) That this meeting approves of the Bill so far as it provides for a conjoint scheme of examination for medical qualification. (2.) That this meeting is of opinion that the profession should have direct representation not only on the Medical Council, but also on the medical boards; and that in Scotland the profession should elect four of the eleven members of the board, thus giving to the universities four members, to the corporations three members, and to the profession four members. (3.) That, in so far as annual fees for the maintenance of registration are concerned, it is the opinion of this meeting that the Bill should not be retrospective in its operation. (4.) That this meeting is of opinion it should be enacted so that the examination for qualification of a student on any subject by his teacher on the same subject be illegal. (5.) That it be remitted to the council of the Society to draw up a memorial embodying the resolutions passed by this meeting, and to forward it to the proper authorities.

PROFESSOR MARSON ON THE UNIVERSITIES BILL.—In an able address to the Edinburgh University graduates last week, Prof. Marson said: "Our Scottish universities, as you know, are once more in the crucible. A Bill is now before Parliament for the appointment of an Executive Commission, with powers to frame regulations for 'the better administration and endowment of the universities of Scotland.' It is not for me here to speak of this Bill in other than the most general terms, or to speak for any one else than myself. My own impression is that the Bill, in its main intention and drift, is a good Bill, and that a wise exercise by well-selected Commissioners of the powers which it proposes to entrust to them can hardly fail to lead to important results that will be both beneficial and acceptable."

THE PROPOSED FEVER HOSPITAL AT CATHCART.—A public meeting of the ratepayers of Cathcart, Langside, and Mount Florida was held on the 18th inst., for the purpose of taking steps to prevent the erection of the proposed fever hospital near Cathcart. The Chairman, Mr. Philip Newton, said the meeting had been called to protest against the proposed erection of a fever hospital in the locality for the burghs of Cambuslang, Rutherglen, Govanhill, and Crosshill. If the movement were permitted to go on without a protest, the result would be that they would soon have fever vans with patients from all the burghs in the combination traversing their roads, and the infected clothing

would be carried along their streets. That would have a detrimental effect upon the district. The new railway was expected to cause a great increase of building, but if the hospital were proceeded with, of course building would entirely cease. Mr. J. W. Swan moved a resolution pledging the meeting to take every legitimate step that it possibly could against the erection of the hospital. Mr. G. W. Muir seconded, and the motion was unanimously agreed to.

EDINBURGH UNIVERSITY COUNCIL.—ELECTION OF AN ASSESSOR.—At a meeting of the General Council of the University of Edinburgh, held on the 17th inst., Principal Sir Alexander Grant presiding, on the motion of Prof. Annandale, seconded by the Rev. Mr. Williamson, Dr. Rutherford Haldane was unanimously appointed Assessor.

EDINBURGH.—HEALTH OF THE CITY.—For the week ending with Saturday, the 14th inst., the mortality in Edinburgh was 92, and the death-rate 21 per 1,000. There were 19 deaths under 1 year and 21 above 60, of which 7 were above 80, and 1 above 90 years. Diseases of the chest accounted for 50 deaths, and zymotic causes for 14, of which 1 was due to fever, 2 to scarlatina, and 1 to measles, the intimations of these diseases for the week being 1, 24, and 18 respectively.

UNIVERSITY OF EDINBURGH GRADUATION CEREMONIAL.—The degree of LL.D. of this University was conferred upon the following gentlemen at the annual graduation ceremonial on Friday last, April 20th:—Robert Berry, Professor of Law, University, Glasgow; William Tennant Gairdner, M.D., Professor of Practice of Physic, University Glasgow; the Hon. Sir Alexander Galt, High Commissioner for Canada; Richard Grunett, of the British Museum; Edward Sang, C.E., Edinburgh; W. C. Williamson, Professor of Botany, Victoria University, Manchester; John Hislop, Secretary to the Education Department of New Zealand; J. O. Halliwell Phillips, of Hollingbury Copse; the Right Hon. George O'Connell Trevelyan, M.P., Chief Secretary for Ireland.

Medico-Parliamentary.

HOUSE OF LORDS.—THURSDAY, APRIL 19TH.

THE MEDICAL ACT AMENDMENT BILL.

The House went into Committee on this Bill.

Clauses 1 and 2, relating to its short title and the Medical Register, were agreed to without discussion.

On Clause 3, referring to the title to

REGISTRATION,

Viscount POWERSCOURT moved an amendment, providing that before any person could be registered under the Act, he or she must have obtained a diploma from one or more of the medical authorities recognised by the Act, and should have become attached to one or more of such authorities.

Lord CARLINGFORD said he could not assent to the amendment, believing that the object which the noble viscount had in view would be sufficiently met by the Bill as he had proposed to amend it. He understood and fully appreciated the object of his noble friend—namely, that under the operation of the Bill the medical bodies should not suffer or lose their *status* and means; and he (Lord Carlingford) certainly did not desire that they should do so, and, as he had already said, that object had been already attained by the amendments he had himself placed on the paper.

After some discussion, the amendment was put and negatived without a division.

Clauses 3 and 4 were then agreed to.

On Clause 5,

Viscount POWERSCOURT, at page 2, line 20, after "hundred," moved to insert "barony."

The amendment was agreed to without a division.

Clauses 5, 6, 7, and 8 were then agreed to.

On Clause 9, which deals with the establishment of

MEDICAL BOARDS,

Lord CARLINGFORD thought it might be of convenience to the Committee if he stated at this point the views of the Government with respect to this matter. And first he would say, that the constitution of the joint boards, as they were commonly called, was a matter of extreme difficulty; it was one of the most complicated parts of the Bill, and one which would require the most careful consideration. But over and above that there was also the question of the comparative representation and influence of the Universities on the one hand, and of the combined medical corporations on the other, and it was no easy task *tantas componere lites*. As regards the Scotch medical boards, the numbers would stand precisely as they were. But with regard to England, it would be seen that although the Royal College of Physicians of London and the Royal College of Surgeons of England returned three members each, while of the Universities some returned two and some one member only, yet in combination the Universities returned a larger number of members than the great medical corporations. He had obtained all the information in his power on this question, and had come to the conclusion that the proportion did not represent the comparative importance in the system of medical examination and licensing, and that the Universities, taken as a whole, were somewhat overrated, while the great medical corporations were somewhat underrated by this distribution. (Hear, hear.) Therefore his proposal was—although it was absolutely impossible to do more than roughly estimate the comparative influence and importance of these various bodies—that the five English Universities should return one member each to the medical board. The result of that would be to give a small majority to the medical corporations, who did so enormous a work in the way of medical licensing. With respect to Ireland the case was different, and so it was in Scotland. There could be no doubt whatever as to the superior claims of the Scotch Universities, but in Ireland the two sets of authorities were rather more equally balanced; but, on the whole, he thought a majority should be given to the Irish Universities. There was an amendment on the paper dealing with the vote proposed to be given to the Apothecaries' Hall of Ireland, and upon consideration he had come to the conclusion that that vote must be withdrawn, for, even if the Government decided to leave the Bill as it then stood, the Medical Council, under the powers proposed to be conferred on them by the Bill, would probably take it away. He proposed that each of the Irish medical authorities, with one exception, should return two members to the joint board. The two authorities which would have returned three members—the Royal College of Surgeons in Ireland and the King and Queen's College of Physicians in Ireland—would return two members. The Royal University of Ireland was to have two members. Trinity College was to have one more member than the Royal University, and the result would be that together they would return five members to the board, and the two Irish medical corporations four. That was the proposal he had to make to their lordships.

The Marquis of SALISBURY thought the action of the noble lord a little extraordinary. He had announced on the second reading the manner in which these different corporations were to be represented on the Council, and, after careful consideration and deliberation on the part of those bodies, they had assented to the course proposed. Now the noble lord came down to the House, and, without any notice, proposed to revolutionise the former scheme as regarded the entire constitution of the Council. What did he think would have been the consequence if Paris had said at the last moment to Venus that she must give up the apple to Juno? (Laughter.) As to the representation of the English Universities, he thought that in striking down their influence the Lord President had not increased the value or dignity of the Council to be constituted. The noble lord also made the strongest possible proposal with respect to the relative values of the Universities themselves. Oxford, Cambridge, London, Durham, and Victoria were all to rank the same. Why did the noble lord stop there? Why was not the nascent Welsh University included as well as another which he believed was in Yorkshire? The proposal of the noble lord appeared to him most unfair to the corporations concerned, and based on an utter misconception of the relative values of the Universities towards each other.

Lord CARLINGFORD pointed out that his present proposal was based on information which he had received since the Bill was printed.

Lord EMLY was astonished at the proposal of the noble lord to give the Royal University and Trinity College, Dublin, two and three members respectively. Out of 880 medical students in Ireland, only 230 were at Trinity College, and the remainder at the Royal University.

Earl GRANVILLE said the discussion proved almost conclusively the impossibility of arriving at any theory of representation which would exactly be justified in all its particulars. He admired the manner in which the distinguished Chancellor of the University of Oxford resented that University being put in the same position as Durham. But with the greatest respect for the University of Oxford, to which he himself belonged, he would say that as a medical University it had not the slightest ground for standing in the same position as the London University, either as regarded the distinction of its medical degrees or the number of its students. He merely mentioned that in order that their lordships might not be led away by considerations of that kind.

The Earl of GALLOWAY said he had received petitions from the Faculty of Physicians of Glasgow, in which they pointed out that the Bill, so far as Scotland was concerned, rather exaggerated the privileges conferred by the Act of 1853.

Earl CAIRNS said that those interested in the English Universities were taken quite aback by the proposal of the noble lord. One of the suggestions of the noble lord was that they should have an even number on the board. He thought that course would be attended with great inconvenience.

The Earl of MILLTOWN thought that the Royal University ought not to be put on the same footing as Trinity College, Dublin. Properly speaking, that University had no students. They merely came up for examination.

The Earl of CAMPERDOWN said he was unable to concur in a great many proposals contained in the Bill as originally drafted. The clause dealt with three Boards—English, Irish, and Scotch. He would suggest that the question of the English Board should be postponed for discussion on report, and that their lordships should now go on with the discussion on the Irish and Scotch Boards respectively.

The Duke of RICHMOND and GORDON preferred dealing with the clause as it stood. The question had not been discussed on the second reading, and those connected with England had no idea that any alteration would be made. Oxford and Cambridge had made of late years enormous strides in all matters connected with medical science, and it would be unseemly to place them upon an equal footing with other Universities which had not done as much for medical science. He suggested that the Medical Board for England should be allowed to remain as it was in the Bill. If his noble friend behind him went to a division he should feel obliged to vote against the proposition of the Lord President.

Lord O'HAGAN and the Earl of BELMORE thought it a great mistake to make any distinction between the two Universities of Ireland.

Lord CARLINGFORD said he was most anxious to take any course that would bring the matter to a fair conclusion, and he would therefore accept the proposal of the noble earl. (Hear, hear.) He would, consequently, strike out the provision that the Apothecaries' Hall should have a representative on the Board, and he would give to the University of Dublin and the Royal University of Ireland three members each instead of two. He also agreed that the College of Physicians should have three representatives, and the Royal College of Surgeons two. As to England, he was very unwilling to take any one by surprise, and therefore he would not press any amendment on the subject at present, but at the same time he reserved his right of placing any amendments on the paper at a future stage.

Lord EMLY thought that the College of Surgeons, as being the teaching body, ought to have three members instead of two, while the College of Physicians, which was not a teaching body, but only a body of trustees, should be content with two.

After some further conversation the clause was amended as to the constitution of the Medical Board for Ireland. Three members are to be chosen by the University of Dublin, three by the Royal University, two by the College of Physicians, and three by the College of Surgeons.

Some further amendments having been made, clause 9 was agreed to.

On clause 10, giving power as to

THE REGULATION OF EXAMINATIONS,

Lord BALFOUR of BURLEIGH proposed the insertion of a proviso to the effect that "such final examinations in medicine, surgery, and midwifery may, for the purpose of this Act, be held at each University by the examiners of the Medical Board, in conjunction with the examiners of the University, or in each division of the kingdom, in conjunction with the examiners of a board formed by the combination of two or more corporations." The object of the amendment, he explained, was to insure, if possible, that it should not be necessary for each candidate to go through two final examinations, and he proposed therefore that the final examination of the divisional board, and that of the University for the degree, shall be held at one and the same time. The reason for the amendment was that the examinations of the Scotch Universities for degrees were very long, tedious, and somewhat expensive affairs, and he thought it might be a hardship if students were asked to go through two such examinations.

The Duke of RICHMOND and GORDON said he could not agree with the proposal of the noble lord. The amendment was designed in the interests of the Scotch Universities, and he advised the noble lord to bring it up at a later stage if he was not then satisfied as to the position to be given to those Universities under the Bill. But even then he could not promise to support him.

Lord CARLINGFORD was quite unable to agree with the Scotch Universities which the noble lord represented upon this point. In his opinion the amendment was absolutely vital to the Bill. The proposal was made mainly in the interests of the Scotch Universities, which were most valuable bodies, but if he were to put the Scotch Universities in a special position, it would be absolutely impossible to carry out a joint scheme affecting the three kingdoms. He was convinced the fears of the noble lord and those whom he represented with regard to the effect of this part of the Bill on the Scotch Universities were quite unfounded.

UNIFORMITY IN EXAMINATIONS.

The Earl of MILLTOWN proposed the insertion in the next sub-section of words with the object of establishing uniformity of standard in the final examinations of the Medical Boards of the different parts of the kingdom.

Lord CARLINGFORD agreed that practical uniformity ought to be attained, but absolute identity of curriculum and everything else would be going too far. They might safely trust the Medical Council and the Privy Council to prevent anything like that undue competition or underbidding between different Universities which had been at times a great blot upon the present medical system.

The amendment was withdrawn, and the clause was agreed to.

Clause 11, enabling a medical board to delegate certain powers to a committee of their body, was struck out.

Clauses 12 and 13, relating to the election of the chairmen and vice-chairmen and to the proceedings of boards, were agreed to without discussion.

Clause 14, referring to the establishment of the Medical Council, was agreed to with some verbal amendments.

Clauses 15, 16, 17, 18, and 19 were then agreed to.

On clause 20, an amendment was moved by Lord BALFOUR, standing in the names of Earl Cairns and Lord Balfour, to this effect:—Page 11, line 4, after "elsewhere," insert "Provided always that examinations passed at a University preceding the final examination required by this Act, if satisfactory to the Medical Council, shall be received by the Medical Board in lieu of like examinations conducted by the Board."

Lord CARLINGFORD pointed out that a satisfactory provision was already made in an earlier portion of the Bill.

The amendment was then withdrawn.

On clause 21,

The Earl of MILLTOWN moved at page 11, line 22, after "authority," to insert "the order of the Board on this behalf being subject to appeal on the part of such examining authority or medical school to the Medical Council."

The amendment was agreed to.

Clause 21 was then agreed to.

FOREIGN COUNTRIES AND THE COLONIES.

On clause 22,

Lord CARLINGFORD proposed several verbal amendments with the object of taking care that foreign countries, or

colonies, should not make use of the powers contained in the Bill for the purpose of obtaining the advantages therein without giving this country corresponding advantages.

The Marquis of SALISBURY said he was much struck with the reference to the principle of reciprocity. He had no doubt they would get to fair trade in time. (Laughter.) He also wished to point out a great grievance in the fact that some drugs were absolutely prohibited in foreign countries, not because they were bad, but because they were prepared out of the country. He thought it might be possible to remedy this defect.

Lord CARLINGFORD said he did not think they had anything to do with drugs in the Bill. If he had charge of a Pharmaceutical Bill in the course of the session he would bear the matter in mind.

Clauses 23 to 26 were agreed to.

Clauses 27 and 28 were agreed to with some verbal amendments.

Clauses 29 to 32 were then agreed to.

Clause 33 was struck out.

Clauses 34 to 37 were agreed to.

On clause 38,

THE PAYMENT OF FEES.

Lord BALFOUR of BURLEIGH moved the following amendment:—"The fee to be paid by University graduates, or persons holding University certificates of having passed the examinations at their University qualifying for admission to the final examination of the Medical Board in medicine, surgery, and midwifery, shall not exceed their proportion of the sum sufficient to cover the cost of the final examination of the Medical Board."

The Earl of CAMPERDOWN said that the noble lord had partly adopted one of the recommendations of the Royal Commission. He thought it ought to be taken in its entirety, and therefore moved to add to the amendment the words "and other expenses aforesaid."

Lord CARLINGFORD agreed with the principle that persons coming from a University to a final examination ought not to be expected to contribute by their fees to support the libraries and museums of institutions with which they had had nothing to do.

Earl CARNS thought that if the amendment were amended as suggested by the noble lord, "the other expenses" might be held to include those which admittedly University candidates ought not to pay.

Some further conversation ensued, which resulted in the amendments being withdrawn on Lord Carlingford's assurance that he would give the question careful consideration before report and amend the clause if necessary in accordance with the principle he had stated. If the noble lord's amendment were adopted *simpliciter* it would, he said, prevent University candidates being charged anything more than the bare expenses of the examination.

Clause 38 was agreed to.

Clause 47, referring to the powers of Colonial Legislatures to make such regulations as they think fit with respect to the operations of the Bill, was struck out.

The remaining clauses were agreed to, in a few instances with verbal amendments, and the Bill was reported with amendments to the House.

HOUSE OF COMMONS.—THURSDAY, APRIL 19TH.

MEDICAL APPOINTMENTS (IRELAND).

Mr. SEXTON asked the Chief Secretary to the Lord Lieutenant of Ireland what was the reason of the delay which had taken place in filling up the vacancy in the medical officership of the Cashel and Grange Dispensary districts, county Tipperary, notwithstanding the regulation that each such vacancy must be filled up within 18 days.

Mr. TREVELYAN—The Local Government Board inform me there is no order in force prescribing that such vacancies shall be filled within 18 days. They further report that in the case of the appointment which was made at Cashel on the 14th February particulars as to age and qualification were not transmitted to them until the 3rd of this month, although the hon. secretary to the committee was pressed to forward them without delay. On receiving the particulars the Board found that the gentleman selected had not reached the prescribed age, and they refused to sanction his appointment, instructing the committee to proceed to a new election. The Local Government Board have no power under the

circumstances described to take the appointment into their own hands under section 8 of 14 and 15 Vict., cap. 68.

VACCINATION IN INDIA.

Mr. P. A. TAYLOR asked the Under Secretary of State for India whether it was the fact that the High Court of Madras had lately decided a case on appeal, to the effect that compulsory vaccination was illegal, the Judges declaring that it was quite optional to a parent whether his children should be vaccinated, and that it was not unlawful to dissuade others from suffering their children to undergo the operation.

Mr. CROSS, in reply, said the decisions of the High Courts in India were not usually reported to the Secretary of State, and he could find no trace of the case referred to by his hon. friend. If he would give him his authority for the facts on which his question was founded he would inquire into their accuracy.

Literary Notes and Gossip.

DR. MURRELL'S "What to do in Cases of Poisoning" (Lewis), seems a success, for it has already reached a third edition. It is much increased in bulk, but even now may almost be called a vest-pocket book.

THE Literary Copyright Convention between Germany and France has been signed at Berlin, and contains, we hear, similar provisions as to the rights of authors as now exist between those countries and Great Britain.

THE ninety-fourth anniversary dinner of the Royal Literary Fund will take place in London at Willis's Rooms, on Wednesday, May 2, when General Lord Wolseley, G.C.B., will occupy the chair.

DR. RICHARDSON'S long-expected work on subjects connected with preventive medicine is, we understand, nearly ready for publication. The volume extends to about 1,000 pages, and includes a history of the phenomena, causes, and prevention of the common diseases affecting mankind. It will be entitled "The Field of Disease."

A REVISED edition of the United States Dispensatory, edited by Dr. H. C. Wood, Dr. Joseph P. Remington, and Dr. S. P. Satler, has just been published by Messrs. Lippincott. The revised edition was rendered necessary by the recent issue of the United States Pharmacopoeia.

FEW names are better known in the profession of the United States than Oliver Wendell Holmes, and as author of the "Autocrat of the Breakfast-table," he is probably equally well known in this country. On Friday last the medical profession in New York gave a banquet in his honour, and the proceedings were of a most enthusiastic character.

A SYSTEMATIC work on hospital construction and management, illustrating the most important pavilion hospitals of various countries, is in the press, from the pens of Dr. F. J. Moutat, Local Government Inspector, and Mr. H. Saxon Snell, architect of several metropolitan infirmaries. The work will be extensively illustrated, and will be issued in sections shortly.

DR. KIRBY'S "Pharmacopoeia of Selected Remedies" (Lewis) has reached a sixth edition, and is much enlarged. It now appears as a quarto of 134 pages. This form is well adapted for the prescriber's table, and so to be ready for reference. There are many useful therapeutical hints, and hundreds of working formulae.

DR. W. H. VAN BUREN, whose death is announced in New York, is best known in this country for his works "On the Surgical Diseases of the Urinary Organs," and that "On Diseases of the Rectum." Dr. Van Buren, remarks the *American Medical News*, was one of the courtly medical men of the old school, who are rapidly passing away, and was

respected not only for his great talents, but for his personal nobility as well.

* *

Health, a new weekly journal, devoted to the popular exposition of sanitary matters, and to the education of the people in the laws of health, has just made its appearance, under the editorship of Dr. Andrew Wilson, who is well known in Scotland as a popular lecturer on health matters. Its programme includes Original Articles, Essays on Personal Health, and departments in which the interests of the family circle, of recreation, and of correspondence on health topics are duly considered.

* *

A SECOND edition of Morton's "Refraction of the Eye" has just been issued by Mr. H. K. Lewis. This little manual of sixty pages is intended to furnish a basis for observation, and to enable the practitioner to diagnose and correctly estimate the value of the phenomena indicating the state of his patient's refraction. In this edition a change has been made in its plan, and some few portions have been partially re-written, and thereby its usefulness has been increased.

* *

"THE new departure" undertaken by the British Association for the Advancement of Science, in holding its next annual gathering out of Great Britain, is meeting with encouraging success. We hear that no fewer than 350 members have already signified their intention of crossing the Atlantic in the autumn, and this number will probably be increased to 500 before the meeting takes place at Montreal. A considerable section of the promises come from medical members chiefly the younger aspirants to fame.

* *

By the death of Dr. Farr the ranks of health and statistical literature have sustained a severe loss. Although never the nominal head of the Registrar-General's office, he was virtually so for a period of forty years, doing the principal work, and controlling the censuses of 1851, 1861, and 1871. His first essay with the pen was as Editor of the *Medical Annual*, and later the *British Annals of Medicine*. In 1838 he was appointed Compiler of Abstracts, and up to within a year or two of his death continued to discharge his duties to the nation, and especially to the profession, by his contributions to the medical and scientific press.

* *

THOUGH comparatively unknown to the present generation, Professor Marcet, whose life ebbed out in London last week at a very advanced age, was held in great repute some fifty years ago. His work on Physics, and his researches in conjunction with Dr. de Candolle, on the action of poisons on plants, were among the best scientific text-books of that period. He will also be remembered by some for his discoveries concerning the boiling point of water, the determination, by freezing, of the specific heat of solids, and the temperature of waters, which gained for him the Fellowship of the Royal Society.

* *

THE *Official Report of the Smoke Abatement Committee* has appeared (Smith, Elder, & Co.), and, by the aid of advertisers' wood-cuts, makes a handsome volume. The results of some of the testings require further corroboration, but many details are given, so that, with a little trouble, much information may be extracted from the tables. We regret to find that gas-stoves without flues are not condemned as they should be in a work of any pretension to sanitary science. The blandishments of advertisers ought not to blind anyone to the danger of any gas-stove from which there is not ample provision for carrying away the products of combustion. It is true that the abatement of smoke was the first object of the exhibition, but that should not be obtained by diffusing poisonous gases through a room.

* *

PROFESSOR MCALPINE, of Edinburgh, in his preface to "Practical Lessons in Elementary Physiology and Physiological Anatomy," just issued (Baillière, Tindall and Cox), remarks that, as physiology is now so commonly taught in schools other than medical, it is worth while trying to make it attractive as well as instructive. In this we think he has fairly succeeded, and the large coloured plate of a frozen section of a child, full size, should alone sell the book at its moderate price. We can hardly say that the drawing and

colouring are anatomically correct, but they are sufficiently so for teaching purposes, and the section is so designed and lettered as to at once impress the student in elementary physiology and anatomy with the relative positions and connections of the internal organs.

* *

THE same work contains a full-size plate of a longitudinal section of a frozen rabbit in the middle line, and by its aid he purposes teaching his subjects by contrast and comparison of the human and animal economies, in pictorial illustrations and simple language. Besides these plates, there are ten others, containing about a hundred drawings of the nervous, muscular, and alimentary systems. The attempt is a commendable one, and we have no doubt that the book will become a favourite one for high schools and science classes. Objection will be taken by some to the size of the book—large oblong quarto—and we are inclined to the opinion that the author might have equally well effected his object with half instead of life-size figures; but time will probably solve this question, as a new edition will doubtless soon be demanded.

* *

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, March 7th:—What to do in Cases of Poisoning (3rd edition), by W. Murrell, M.D. Gout in its Protean Aspects, by J. Milner Fothergill, M.D. A Treatise on Fractures, by Lewis A. Stimson, M.D. How to Examine the Chest, by S. West, M.D. The Hunterian Oration, 1883, by Spencer Wells, F.R.C.S. Dental Vade Mecum, by Jas. Hardie, L.D.S. Plumbing and House Drainage, by W. P. Buchan. Vaccination: its Place and Power, by T. M. Dolan, F.R.C.S.E. Student's Guide to Dental Anatomy (2nd edition), by Henry Sewill, M.R.C.S. Formulaire des Maladies des Voies Urinaires, par F. Mallez. On the Pathology of Bronchitis, Catarrhal Pneumonia, Tubercle, and Allied Lesions, by D. J. Hamilton, F.R.C.S., F.R.S.E. Clinical Lectures on Diseases of the Urinary Organs, by Sir Henry Thompson, F.R.C.S. Manuel des Injections, par les Drs. Bourneville et Bricon. Dr. G. Beck's Therapeutischer Almanach. Annual Report of the Cumberland, Westmoreland, Gloucester, and Derbyshire County Asylums. Elementary Meteorology, by R. H. Scott, F.R.S. Text-book of Physiology, by M. Foster, M.D., F.R.S. (4th edition). Student's Manual of Venereal Diseases, by Berkely Hill and Arthur Cooper (3rd edition). Transfusion: its History, Indications, and Modes of Application, by C. Egerton Jennings, L.R.C.P.Lond. Practical Lessons in Elementary Physiology and Physiological Anatomy, by D. McAlpine, F.R.C.S. Lectures on Cataract, by George Cowell, F.R.C.S.

Obituary.

WILLIAM FARR, M.D., F.R.S.

By the death of this esteemed gentleman the profession has lost a more than ordinary member from its ranks, and the public a faithful guardian of more than forty years' service. No matter who might be the nominal Registrar-General, Dr. Farr was the actual working registrar, and his labours have probably had a greater and more lasting effect upon the last two generations in sanitary and health matters generally than all the laws on the subject that preceded him. His name, in fact, became a household word in its truest and most acceptable form, and England may well feel proud of a son whose teachings have formed the basis of the sanitary enactments of almost every civilised nation.

William Farr was born at Kenley, Shropshire, in 1807, and was educated at the Shrewsbury Grammar School, and subsequently at the Universities of London and Paris. In 1832 he took his first diploma, L.S.A. Lond. In 1867 Trinity College, Dublin, bestowed on him the distinction of M.D., and the King and Queen's College of Physicians in the same year elected him to the Honorary Fellowship of their body; and subsequently the Blue Ribbon of Science, the F.R.S. of Great Britain, fell to him, as well as the Hon. D.C.L. Oxon. From 1836 to

1839 he was editor of *The Medical Annual*, during which period he contributed various articles to current literature on "Vital Statistics," "Life Assurance in Health and Sickness," "A Method of Determining the Danger of the Duration of Diseases at every Period of their Progress," &c. Since then his essays have been of the most voluminous description, and as valuable as they were many; space does not permit of our chronicling these in detail, as a bare list would occupy several columns of type; but in all matters concerning the censuses, the health or sickness of the community at home, or the importation of plagues from abroad, Dr. Farr was the guiding spirit of the health office of this great Empire, and well and faithfully did he discharge his responsibility. Upon his retirement some three or four years since from the Assistant Registrar-Generalship the Government voted him a handsome retiring pension, and a considerable sum was also subscribed for him by the profession and the public; and many sincere mourners outside the family pale were to be seen at his funeral on Saturday last, to show their last mark of respect to his memory.

Correspondence.

LISTERISM.

We have received for publication the following correspondence:—

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I lately addressed a letter to Professor Lister (a copy of which I enclose), asking him if he still uses the spray in his operations, dressings, &c. I enclose his reply, which I consider important, to avoid any misapprehension on a subject of so much importance as the "antiseptic dressings" demand from the hands of all modern surgeons. I also wish to correct any errors in the minds of students who may be misinformed on "Listerism." Your inserting this and the distinguished Professor's reply will oblige

Yours truly,

HENRY GRAY CROLY,
Senior Surgeon, City of Dublin Hospital.
7 Merrion Square, Dublin, April 20, 1883.

My dear Mr. Lister,—Will you kindly inform me if you still use the spray as part of the dressings in your operations, and also if you use it at your operations as heretofore? There are a few persons here who state that you have long since given up the use of the spray, and I wish to have an answer from the "fountain head."

Faithfully yours,

HENRY GRAY CROLY.

Dear Mr. Croly,—I have not given up the use of the spray, although I certainly regard it as the least important part of our antiseptic arrangements. Whatever other good it may do, it is a very mild form of antiseptic irrigation, and tends to keep the *entourage* of the wound, including the surgeon's hands and instruments, pure. But if I had not a spray-producer at hand, I should not on that account omit other elements of antiseptic treatment. I still use the spray in changing dressings, so long as the wound is not merely superficial. But far more important than using the spray is it to make a point of covering the wound with some pure aseptic material before beginning to wash the parts which were covered with the edge of the dressing only, and were therefore impure. In other words, I believe one of the commonest causes of failure is dabbing alternately the impure surrounding parts and the pure wound with the same piece of rag, which, though moistened with carbolic lotion, cannot work miracles.

Believe me, yours very truly,

JOSEPH LISTER.

REDUCTION OF PARAPHIMOSIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with interest Mr. Ormsby's able lecture on phimosis and paraphimosis. I would, however, wish that he and your readers would give a trial to my method of re-

duction of paraphimosis—viz., by winding round the constricted part closely and firmly from before backwards ordinary strong twine, so driving the exuded serum through the constriction, and then pulling forwards the prepuce on unwinding the twine. They will find it nearly painless. I have always found it successful.

Yours, &c.,

M. R. O'CONNOR, M.D., M.Ch.

Limerick Union Hospital, April 19, 1883.

Royal College of Surgeons of England.—The following candidates, having passed the required examinations, were admitted Members of the College at a meeting of the Court of Examiners on Monday, April 16th:—

Barley, David H., M.B. Durh.
Betts, J. Howard, M.D.
Byant, Sidney W., M.B. Edin.
Evans, Owen H., L.K.Q.C.P. Irel.
Hartley, Isaac, M.B. Durh.
Johnson, Geo. A., L.R.C.P. Lond.

Maxwell, Patrick W., M.B. Edin.
Money, Percy F., L.R.C.P. Edin.
Munckton, Alfred, L.S.A.
Rowland, John Jones, L.S.A.
Smith, Pysent C., L.R.C.P. Edin.
Vinrace, Edward Dennis, L.S.A.

The following were admitted on Tuesday, April 17th:—

Floyer, Frederick A., L.S.A.
Head, Hugh.
Herbert, J. W. Chambers.
Johnson, George David,
Littlewood, Harry.
Marten, Robert Humphrey.

Meyer, C. H. Louw.
Pinching, Horace Henderson.
Pucin, Septimus Tristram.
Thompson, Charles Herbert.
Williams, David Lewis.
Williams, J. H. Hywell, L.S.A.

The following were admitted on Wednesday, April 18th:—

Bentley, John W., L.R.C.P. Edin.
Bloxam, Geo. E., L.R.C.P. Lond.
Bostock, John Yates.
Braine, G. M. P., L.R.C.P. Lond.
Crago, W. H., L.R.C.P. Lond.
Cresswell, Francis, L.R.C.P. Lond.
Groom, Harry, L.S.A.

Humphreys, Chas. Style, L.S.A.
Jordan, Thos. Luckman.
Rudd, Walter Edgar.
Stone, F. W. S., L.R.C.P. Lond.
Vogan, J. N., L.R.C.P. Lond.
Whitcombe, Philip P., L.S.A.
Winter, Thomas Bassell, L.S.A.

The following were admitted on Thursday, April 19th:—

Anderson, L. McEwan.
Bartlett, Benjamin Pope, L.S.A.
Blampied, John William, L.S.A.
Cater, John R.
Cree, Herbert E.
Dabbe, Charles J.
Hind, Alfred F.
Malcolm, John D., M.B.
Manley, J. H. Hawkins.
Merces, James.

Rabbeth, Samue.
Robson, W. W. C., L.R.C.P.
Ryle, Reginald John.
Slater, Druce John.
Square, Edward Herbert, L.S.A.
Wat-on, William.
Welster, William Frederick.
Wilson, Thomas, L.S.A.
Wright, Holland Hodgson.

King and Queen's College of Physicians in Ireland.—

At the usual monthly Examinations for the Licences in Medicine and Midwifery, held on Monday, Tuesday, Wednesday, and Thursday, April 9th, 10th, 11th, and 12th, the following were successful:—

For the Licences to practise Medicine and Midwifery.

B-y', Campbell.
Boyd, Bhepherd.
Curr, Michael.
Hall, Thos. Gibson Henry.
Ho-y, Patrick.
Kelly, A. J. Garvey.

Lemson, Edw. Emmanuel.
McIeerney, Thomas.
McQuaid, M. Joseph.
Morier, C. G. Drummond.
O'Brien, H-nry Joseph.
Ryan, James Dwyer.

For the Licence to practise Medicine only.

Hudamith, Powell.

Mackenzie, Alex. Linton.

The following Licentiate in Medicine of the College, having complied with the by-laws relating to membership, has been duly admitted a Member of the College:—

O'Reilly, George J., Licentiate, 1875.

At a special Examination for the Licences in Medicine and Midwifery, held on Monday and Tuesday, April 2nd and 3rd, the following candidate passed:—

Morgan, George John, M.R.C.S. Eng., 1868.

University of St. Andrews.—The following registered medical practitioners, having passed the required examinations, had the degree of Doctor of Medicine conferred upon them on April 18:—

Andrew, J. Lawton, L.R.C.P. Ed., M.R.C.S. Eng., Mossley, near Manchester.
Astles, Harvey Eustace, F.R.C.P. Ed., Adelaide.
Brown, Andrew, M.R.C.P. Ed., L.R.C.S. Ed., London.
Fisher, Henry Francis, L.R.C.P. Ed., L.F.P.S.G., Liverpool.
Gambier, Thomas, M.R.C.S. Eng., St. Leonard's-on-Sea.
Giddings, W. Kitto, M.R.C.P. Ed., M.R.C.S. Eng., Calverly, Leeds.
Jamieson, James, F.R.C.S. Ed., Edinburgh.
Jay, Frederick Fitzherbert, L.R.C.P. Lond., M.R.C.S. Eng., Slough.
Kempster, William Henry, L.R.C.P. Ed., M.R.C.S. Eng., London.
Smith, Thomas, F.R.C.P. Lond., F.R.C.S. Ed., Woodley, Stockport.
Hanson, John Edward, M.B. and C.M. St. And., Huddersfield.

At the same time the following gentleman passed the first professional examination for the degree of Bachelor of Medicine and Master in Surgery:—Martin, John, L.R.C.S. Ed., L.A.H. Dublin, A.M.D., Cork.

Notices to Correspondents.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

MR. F. E. W.—Three cases of gastrostomy for cancer of œsophagus are reported in a recent number of the *St. Petersburg Med. Woch.* One died shortly after the operation from perforation of the bronchus by extension of the carcinomatous ulceration. The other two recovered from the operation—one dying eight months afterwards from the original disease and the other being still under observation.

A CANDIDATE FOR THE FELLOWSHIP.—Gross's "System of Surgery" will be found a thoroughly reliable guide: the sixth edition is quite up to date, and the author has adopted the plan of Gant's "Surgery," by enlisting a number of collaborateurs to write chapters on special subjects and operations.

THE INFLUENCE OF ELECTRIC LIGHT ON THE EYES.

PROF. MAUTNER, in a communication to *Allgemein. Wien. Med. Zeitung*, says that in estimating the influence of the electric light on the eyes, three factors must be considered:—1. The constancy of the light. 2. Its brightness and illuminating power. 3. The colour. As to the first point, the electric arc gives an inconstant or unsteady light, and is therefore injurious to the eyes. The illuminating power is too intense, and is on that account injurious; and, finally, the colour is not purely white, and on this account also it may prove injurious.

EXAMINATION IN SANITARY SCIENCE.—At the Examination in Sanitary Science held on the 12th and 13th inst. at the King and Queen's College of Physicians, Thomas Lane, L.R.C.S.I., L.K.Q.C.P.I. & L.M., son of the late Thomas Bagot Lane, M.B., F.R.C.S.I., of Tullow, co. Carlow, obtained the Certificate granted by the College.

MR. H. C. B.—We look at the matter from quite another point of view, and are not willing to give a gratuitous advertisement of what is no more than a common commercial article.

CHLOROFORM BREATH.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—As a corollary to your French correspondent's remarks in last week's *Medical Press*, I may mention that this phenomenon is not confined to gastric disturbance. It is at times common immediately after sexual connection, and during the act a naturally foul breath may become quite sweet and of a distinct chloroform odour.

The explanation is to me a mystery, but I am positive as to the fact. I am, yours faithfully,

A MARRIED M.R.C.S.

SOUTH-EASTERN.—Probably a case of well-water contamination. The water from the main from which your district is supplied was reported last month by the Government water examiners as absolutely pure, bright, and well filtered.

G. A.—Nobody but the dispensary medical officer is entitled to fee for examining dangerous lunatics. See Lunacy Act, Irish "Medical Directory," page 510, sec. 10.

AN URGENT APPEAL.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I venture to appeal on behalf of the widow and three children of Benjamin T. Moore, M.D., who died at Kineton yesterday, leaving his family in the most complete and utter destitution. They are totally unprovided for in any way, and are literally penniless.

Any subscriptions, however trifling, to tide Mrs. Moore over the present until some steps can be taken for her, will be thankfully received by the Rev. F. Miller, M.A., Kineton, Warwick.

I am, yours faithfully,

Kineton, Warwick, KENNETH W. MILLICAN, M.R.C.S.
April 21st.

STATIST.—Our sole reason for not including Madrid amongst our weekly returns of mortality of the principal foreign cities is because the figures are unattainable. Spain, unfortunately, is not on a level with the sanitary teachings of the age, and no reliable record of the death-rate of Madrid or other large city in that country ever finds its way to this.

MR. WILKINSON.—The objects of the Society are very praiseworthy, and deserve support. The work is carried on quite gratuitously by its officers, and much good has resulted from its operations.

DR. R. D. NICHOLS will receive a private note on the points about which he is anxious.

THE PROFESSION AT THE LEVEE.

By command of the Queen a levée was held on Monday last at St. James's Palace by H.R.H. the Prince of Wales, on behalf of her Majesty, when the following medical officers of the Army and Navy Departments had the honour of presentation:—

Surgeon Major J. M. Beamish, M.D., on promotion and return from Egypt; Surgeon H. Charlesworth, on return from active service; Fleet Surgeon M. A. Harte, R.N.; Surgeon G. H. Le Motteé; Surgeon Major G. F. Hume-Spry, M.D., on return from active service; Surgeon Major F. B. Scott, C.M.G., on return from active service; Surgeon Major Edric Selons, M.D., Indian Medical Service.

A MEMBER OF CONGRESS.—We understand that a second edition of the picture, with additional portraits, was published recently. We would advise you to communicate with the publishers on the other points referred to in note.

MEETINGS OF THE SOCIETIES.

WEDNESDAY, APRIL 25TH.

HUNTERIAN SOCIETY.—At 8 p.m., Adjourned discussion (to be opened by Dr. Stephen Mackenzie) on a paper by Dr. Stowers, On the Nature and Treatment of Infantile Eczema.—Dr. Bedford Fenwick, On Medical Common Sense in the Treatment of Chest Complaints.

FRIDAY, APRIL 27TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. Tyson (Folkestone), On a Case of Tubercular Leprosy. (The patient will be exhibited.)—Mr. Barwell, On Removal of Large Portions of the Upper Lip without deformity of the face.—Dr. Southey, On Tachetée, or Erythema Gangrenosum.—Dr. Stephen Mackenzie, A Case of Subcutaneous Nodules occurring in a patient the subject of Syphilis, and with very indefinite Connection with Rheumatism.—Dr. Duckworth, A Case of Rheumatism, Cutaneous, Subcutaneous, and Periosteal Nodules.

ACADEMY OF MEDICINE IN IRELAND (Obstetrical Section).—At 8.30 p.m., Specimens exhibited by card: Dr. Macan, Dermoid Cyst of both Ovaries, removed by Operation.—Papers: Rev. Dr. Haughton, F.R.S. (for Surgeon W. C. Ashe, B.A.), On a Remarkable Case of Protrusion of the Uterus with Ovarian Disease in a Cingalese Woman, near Kandy.—Dr. T. More Madden, On some of the Nervous Diseases peculiar to Women.—Dr. Macan, Notes on the Specimens exhibited.

MONDAY, APRIL 30TH.

ROYAL INSTITUTION.—At 3 p.m., Prof. McKendrick, Physiological Discovery.

MEDICAL SOCIETY OF LONDON.—At 8 p.m., Various Communications.

Vacancies.

Eastern Dispensary of Bath.—Resident Medical Officer. Salary, £100, with furnished apartments, &c. Applications to be sent to the Hon. Sec. before May 7th.

Royal Westminster Ophthalmic Hospital.—Assistant Surgeon. Honorary. Applications to the Committee before May 2nd. (See Advt.)

Wexford Union, Bridgetown Dispensary.—Medical Officer. Salary, £100, and £15 s. Medical Officer of Health. Election, May 7th.

Western General Dispensary, Marylebone Rd., N.W.—Resident House Surgeon. Salary, £120, with furnished apartments, &c. Applications to be sent to the Secretary on or before May 7th.

Westminster Hospital Medical School.—Chair of Anatomy. Particulars may be obtained on application to the Dean. Applications will be received up to May 1st.

Appointments.

CAVERHILL, T. F. S., M.B., M.R.C.P.E., Assistant Surgeon to the Edinburgh Eye Dispensary.

COLMER, P. S. H., M.D., L.R.C.P. Ed., L.F.P.S. Glas., Medical Officer for the Second District of the Yeovil Union.

FARMER, S., L.R.C.P. Ed., M.B.C.S., Medical Officer for the Western District of the Redruth Union.

JONES, J. E., M.B., C.M. Glas., Medical Officer for the Aberdaron District of the Pwllhell Union.

KNIGHT, F., M.R.C.S., House Physician to the General Lying-In Hospital, York Road, Lambeth.

MARSH, J. J., L.R.C.P., Honorary Surgeon to the Ardwick and Ancoats Dispensary and Ancoats Hospital, Manchester.

O'KELLY, T., M.D. Q.U.I., Medical Officer for the Second District of the Chipping Norton Union.

PAXTON, J., Jun., L.R.C.P., L.R.C.S. Ed., Medical Officer for the East Northamptonshire District of the Berwick-upon-Tweed Union.

Births.

BARKER.—April 19th, at 87 Harley Street, Cavendish Square, W., the wife of Arthur E. Barker, F.R.C.S. Eng., of a daughter.

BROWNE.—April 9th, at Frankford, the wife of Thomas H. Browne, L.R.C.S.I., L.K.Q.C.P.I., of a daughter.

CADELL.—April 12th, at 4 Buckingham Terrace, Edinburgh, the wife of Francis Cadell, M.B., F.R.C.S. Ed., of a son.

HEGARTY.—April 17th, at Clonbur, co. Galway, the wife of J. Hegarty, M.D., of a daughter.

TWINING.—April 17th, at the Knoll, Salcombe, South Devon, the wife of A. H. Twining, M.B.C.S., of a daughter.

Marriages.

HUSBAND—BRADSHAW.—April 19th, at St. Mary's, Charlcombe, Bath, Walter Edward Husband, L.R.C.P., of Manchester, to Lucy Everlina Augusta Berkeley, only daughter of the late Captain Bradshaw, B.A.

Deaths.

BATT.—April 16th, at Bournemouth; Augustine Batt, M.D., of Witney, Oxfordshire, aged 64.

BRENDON.—April 19th, at 75 Inverness Terrace, Hyde Park, Peter Brendon, F.R.C.S., formerly of Highgate, aged 85.

CAREY.—March 31st, at Hauteville, Guernsey, Robert Gledstanes Carey, M.D., aged 70.

DUFF.—April 15th, at Gray's Inn Road, London, after a short illness, William Henry Duff, M.R.C.S., L.S.A., aged 67.

FARR.—April 14th, at Forton-road, Maiden Vale, W., William Farr, M.D., C.B., D.C.L., late of the General Register Office, Somerset House, aged 75.

HOLLOWAY.—April 19th, at Notley, Surgeon-General James Lewis Holloway, C.B., A.M.D., aged 57.

ON THE WINTER HEALTH RESORTS OF THE ALPS.

By E. SYMES THOMPSON, M.D., F.R.C.P.,
Senior Physician to Hospital for Consumption, Brompton.

It is a fact now generally accepted by the profession and by the public, that a winter spent in the High Alps is often productive of great benefit in cases of chest disease. Hitherto it has been deemed needful to reach the selected health resort in September or October before the snows and frosts of winter have set in, and travelling has become dangerous. It is, however, my object in this paper to point out from personal experience, that travelling is seldom if ever dangerous, that it may easily be accomplished at any time with due precautions, and by suitable patients, and that not only chest complaints but many others may be benefited by a winter sojourn in the Alps. The long winter journey of which the very *idea* alarms our patients at first sight, is really a simple matter. Leaving London at 10 a.m., and Dover at 12, you take luncheon at Calais, coffee at Amiens, and dinner at Tergniers, soon after which you settle down for a night in the train. This is a fatigue to some, but a large proportion of travellers quickly fall asleep, especially those who have been living at high pressure to enable them to get free for the much needed change, and the railway carriage is kept comfortably warm by a somewhat too frequent supply of hot water tins. At six in the morning you are ready for a wash and breakfast at Basle, and at about half-past seven the glories of the journey begin. Zurich and the Lake of Wallenstadt are seen in a flood of sunlight, such as we Londoners have not enjoyed since August, and on arriving at Chur at 2 p.m. it is almost impossible to believe that only 28 hours before you were wearily driving to

Charing Cross through the foggy London streets. Still more refreshing is it to exchange the iron horse for *Swiss* horses of flesh and blood. The three hours drive from Chur to Thusis seems to break off the links that bind to artificial life and land one in a region of peace, not yet, however, quite snow begirt, for the roads are thus far passable for wheels as well as for runners. At Thusis warm bed-rooms, a good dinner, and a hospitable English-speaking host await you at Hotel Rhoetia. Above this point sledges only are used. The drive over the Julier Pass to St. Moritz, some parts of it in open sledges and some in a diligence on runners, is full of incident; and, notwithstanding the cold, marvellously free from discomfort. It commences at 7 a.m. and occupies the greater part of the day, and I can speak from experience not only as to its freedom from chill and suffering, but for the renovation and refreshment it brings even to the invalids. It so happens that four of my patients crossed this Pass during storms, the two chief storms of the season; although the sledges were several times upset in the snow the patients were none the worse, but all the better for the trip.

In the journey to Davos the destination is reached before 3 o'clock, a consideration this, for those who are weak, as will be shown presently. Davos is better suited for the more fragile, and St. Moritz for those who can bear a long day in the free air. As regards meteorological data the information is incomplete and somewhat conflicting. Theory would lead me to suppose that as the two valleys of the upper Engadine and of Davos are similarly placed the diversities would not be great, especially as the distance between them is scarcely fifteen miles, and the mountains on either side allow a similar amount of diurnal sunshine. The Engadiner Kulm is however nearly 1,000 feet higher than Davos, and is raised farther above the level of the valley, which, in the first case is occupied by the St. Moritz Lake, and in the latter by a flat plain, marshy in summer, but snow covered in winter.

The rainfall is about the same; when south winds prevail there is more snow at St. Moritz, but in north winds more at Davos. I have before me the wind gauge observations at Davos and St. Moritz but they are conflicting, and I am assured by competent authority that no reliable figures exist by which the two places can be compared. The last column in the table shows the number of absolutely windless days at Davos during the last four winters. The Föhn wind from the south, which is sometimes compared to the Sirocco, is described by the Davosians as relaxing and trying to invalids, whilst at St. Moritz its influence is less depressing.

elevation, may be too great for many invalids with whom it may be wise to begin with an experience of the lower levels before making trial of the upper, and to ascertain how 5,000 feet is borne before trying a 6,000 feet elevation. Then, again, the usual habits and tastes of the invalid must be considered. The life at Davos is suited for those who enjoy strolling up and down the main street, amid a crowd of other loiterers, admiring the shops and sleighs, and listening to the band at the Curhaus. There is not much stimulus to over-exertion there, as the skating rink is at a distance of nearly half a mile below the hotels, and is not always well kept. At St. Moritz the skating-rink is flooded daily by the

Mr. Waters, whose observations at Davos in the winter of 1881-2 were made most carefully, and who is now carrying out a series of elaborate investigations, finds that this Föhn wind contains more moisture at St. Moritz than at Davos; this he attributed to the fact that before it reaches Davos the moisture is deposited in the form of snow on the intervening mountains.

In the Alps, as on the Riviera, the fine seasons are not the most favourable to invalids, who are then tempted to exert themselves over much, and so set up catarrh, hæmoptysis, or some intercurrent affection. More progress is made when occasional bad days keep the invalids indoors, and show them the necessity for avoiding undue exposure and exertion.

Last winter was exceptionally fine, and had this disadvantage; that at Davos the snow was frequently melted and in a state of slush, and thus the dryness was lessened, and mists promoted.

The elevation of St. Moritz being greater, it may be assumed that the influence of the rarefied air is also greater in expanding the chest, increasing its dimensions, and furthering replacement of damaged and cicatrising parts by neighbouring healthy lung. One of my cases afforded a good example of the expansion of the sound lung replacing the contracted lung.

For the same reason it might be expected that those who, having extensively damaged lung, suffer from dyspnoea at Davos would do so more painfully at St. Moritz. I have met with several cases of this kind in summer. This winter, however, the only cases I saw, in which breathlessness was complained of, happened to be at Davos.

The exhilarating quality of the air is more apparent at St. Moritz than at Davos, owing partly to the greater elevation, and partly to the surpassing beauty of the surrounding scenery. This exhilaration, and the 6,000 feet

hotel keeper, and the toboggan runs are at the very door of the Hotel. There is also a well kept lawn tennis court in the grounds of the hotel. The life, therefore, at St. Moritz is like that of a large country house in England, where all have like interests, aims, and pursuits.

With the exception of an occasional treat of glee-singing by the villagers, every entertainment given is designed, executed, and appreciated by the hotel guests. There is no temptation to seek evening amusement under any other roof.

Although the weather of the Alps is more steady and reliable in winter than in summer, we cannot compare one winter with another without observing many great variations. Taking the figures and throwing them into the form of a comparative table, we find on adding together the two first columns, the fine days are 109, 86, 140, 115, giving an average of 112. Even the worst of these rouses in the breast of the Londoner a longing for the Alps.

In favourable winters the invalid at Davos has more out-door air than in the Riviera, and can enjoy much more fresh air in his room than in most warm resorts. The air at Davos is drier than either that of the Riviera or of Egypt (a) and being cold as well as dry, it can, when inspired and so raised nearly to blood heat, absorb a great deal of moisture from the lungs. The amount of moisture absorbed from the skin is also very great. Besides the dryness of the air, its rarefied nature facilitates the interchange of oxygen and carbonic acid to and from the blood.

Davos gained its early reputation when a simple mountain village. Now it is quite a town, with its baths,

(a) "Mr. A. W. Waters' Observations at Davos, 1881-2." "Proceedings of the Manchester Literary and Philosophical Society, 1902."

gas works, and large shops, curhans, and hotels. Eleven years ago, the hotels were filled only in summer, and in winter afforded ample accommodation for the small number of guests who ventured to frequent them. This is now reversed. The hotels are more than adequate for summer visitors, and overcrowded in winter.

St. Moritz is now in the position that Davos was eleven years ago. The hotel built for 300 summer visitors is more than sufficiently large for the requirements of its 100 guests, who are able to enjoy abundant breathing space, large, well-warmed room, and spacious corridors for exercise.

The position of the Davos valley, enclosed and protected from the north and east, becomes, as the town enlarges, a source of danger, the smoke caused by lighting fires in the morning often hangs over the town for the whole day. Overcrowding has spoilt many a haven on the Riviera, but overgrowth is far more to be feared in an enclosed valley than on the sea coast. The drainage, the defects of which have kept many away is about to be improved by deepening the course of the Land wasser stream, and making it more direct. The warming of the hotel is effected entirely by stoves, and no sufficient provision exists for the extraction of the air; it remains, therefore, for each person so to manage the ventilation of his room as to secure adequate interchange. This may be effected by having a portion of the window open, and thus obtaining a constant admission of air. The atmosphere is so still and dry that no draught is thus occasioned, and no sudden chilling of the room. The admixture of inner and outer air is secured, not by currents of air or draughts, but by a gradual and unnoticed interchange.

If at bedtime the temperature of the room is 58°, and the window kept partially open all night, the morning temperature seldom falls below 48°, and the stove being lighted before the invalid gets up, there is no danger.

In England, with a similar access of air, and an open fireplace, the moisture contained in the outer air, and the draught from the window to the fire would give a serious chill. The ordinary French windows are double, and it is usual to open the outer window to the extent of three or four inches, and the upper fan light of the inner window to a similar extent; thus, the outer air mixes with the air between the inner and outer windows and then enters the room in an upward direction.

The Engadine is acknowledged to be one of the most enjoyable places in which to spend a few weeks in summer, but it is even more renovating and refreshing in winter to persons in ordinary health. The weather is more reliable and unvarying, there is no risk of enervation from excessive heat during the journey, the sky is cloudless, there is no rain, and snow falls but rarely.

If the hard-worked man of business can secure a month for rest and change, he may gain the needed benefit in any of the favoured health resorts of our own island, but if a week or two can alone be obtained, he should seek out a mountain station sheltered from wind and having the proper aspect and necessary comforts. The journey may be considered as forming part of the pleasure, and its cost (about £10 the return fare) is fully repaid by the rapidity of convalescence and speedy return home.

Overworked schoolmasters and professional men needing rest can do nothing better than make a short trial of the Engadine, and Davos in winter. From the southern health resorts the friends of the patient are apt to return debilitated and unstrung; it is quite otherwise in these mountain stations. I knew of no place so good for a schoolboy and his sisters in the winter holidays as the Engadine.

Those in health need few restraints, but for those with active lung disease, sudden exertion on arrival should be discouraged lest it lead to hæmorrhage. It is not easy to regulate exercise. If there is active disease

or hæmorrhagic tendency, or moist sound in the lung, the patient should sit out in the sun till dry sounds replace moist ones. He may then walk on the level, or skate, or gently stroll up and down hill, thus causing deep inspiration. Quiet skating can be indulged in by almost all. "Tobogganing" is more severe, as patients are apt to talk and laugh when walking together up hill. This is very good for the vigorous, as it expands the chest. Lawn tennis is suited only for the strongest, in whom lung disease is quiescent.

The journey home! Here the difficulty meets us where to go when the snow is melting, and some stay at their winter quarters till they can safely return to England, and others try Switzerland, Italy, the Black Forest, or the Rhine. No hard and fast line can be drawn for all, but when the patient is too ill to enjoy the incidents of a tour, and is too tender to be exposed to the risks of hotels and railway platforms, the best course is to travel as directly and rapidly as possible from the winter haven to the English home. Leaving Davos one morning you can be in London on the afternoon of the following day.

A winter passed in the South of France renders a return to England unsafe till the middle of May, but if spent amidst frost and snow, the ability to bear extremes is strengthened, and the dangers of our English climate are scarcely to be feared. One of the advantages indeed of a winter in the snow is this increased power of enduring bad weather on the return home.

To gain full benefit from St. Moritz a patient should be well and strong enough to maintain his circulation by his own exertion, even in rough weather the air is dry and very bracing, and the patient returns to the hotel in good spirits and with an appetite for his dinner. There are many people, especially those who live in the country and come daily to town for business who might do well without leaving home, or even their work, during the summer when the days are long enough for ample open air exercise (besides the hours spent in the office or place of business), when the foggy and short sunless days of November and December come, then is the time to be off to Biarritz, to the Riviera or to the Alps. Such a plan as this, would, I believe, prove of permanent benefit to many, would arrest deterioration and premature decay, and, as regards the children, a winter holiday at St. Moritz is, as I have said, of unparalleled advantage. While advocating the direct journey home in certain cases, it must not be forgotten that, where there is a hæmorrhagic tendency it is wise to make the change gradually, to this end a few days may be wisely spent on the Lake levels and at an intermediate level, at Thusis, for instance.

Cases in which there is marked arterial degeneration do not bear the change well, and need especial care in accomplishing the journey by gradual ascents.

(To be continued.)

RHEUMATISMAL, CUTANEOUS, SUBCUTANEOUS, AND PERIOSTEAL NODULES. (a)

By DYCE DUCKWORTH, M.D. Edin., F.R.C.P. Lond.,
Assistant Physician to St. Bartholomew's Hospital, &c.

M. F., æt. 38, a married woman with one child, came under Mr. Langton's care at St. Bartholomew's Hospital, in December, 1882, for the treatment of multiple fibrous nodules on the arms and legs. She was active and robust, with fresh, rather florid complexion, and fair hair. Teeth nearly all decayed and lost. The history was that "a lump" first came on the right elbow in September, 1879, another on the right knee soon followed, and others have

(a) Abstract of paper read before the Clinical Society of London, April 27th, 1883.

appeared on the limbs from time to time. They were found in the several positions hereafter mentioned. *Right Ulna*—A large tumour (size of a penny), freely movable, not adherent to the periosteum. Below this, two others, much smaller, adherent to the periosteum. None over the radius. One firmly attached to the anterior ligament of the wrist; one in the palm of the hand; and one on the third phalanx of little finger. *Left Ulna*—One four inches below olecranon, small, slightly movable, not adherent to the skin. None on the radius. On the palm of the hand six small nodules, adherent to the skin. *Right Leg*—One over lower angle of patella, movable, not attached to the bone, about the size of a penny. Another, two inches below patella, much firmer, freely movable, and adherent to the skin. Numerous small ones on the crest of the tibia, to within five inches of the ankle, firmly adherent to periosteum. Several over upper part of fibula, firmly adherent to periosteum. No nodules found on the scalp, scapulæ, spinous processes of vertebræ or feet. The tumours were very painful, and ached more in cold weather. There was no personal history of rheumatism or of chorea in this patient. Her mother, however, was rheumatic, and a sister had had three or four attacks of rheumatic fever. Examination of the heart revealed nothing worthy of note. There was perhaps doubtful roughness of the first sound of the apex. Iodide of potassium was given, and during the past three months there has been a gradual reduction in the size of the nodules, and some of them have become softer. Having regard to the clinical features of this case, and to the family rheumatic predisposition, Dr. Duckworth ventured to call these nodules rheumatic in their nature, and he believed that further study of these cases showed that there are several types or varieties of them. This case, as well as that one exhibited by him at the beginning of this session to the Society, illustrated a form met with in adults in which the nodules are very persistent, and are also attached to the skin and periosteum. Amongst the first cases brought forward by Drs. Barlow and Warner, the nodules were found to be commonest in children and young persons, to be subcutaneous, not to have any periosteal attachment, and not to last more than a few weeks or months. In this instance, the nodules have lasted for two years and six months, and in the other for one year and six months.

SUBCUTANEOUS NODULES OCCURRING IN A PATIENT THE SUBJECT OF SYPHILIS, AND WITH VERY INDEFINITE CONNECTION WITH RHEUMATISM. (a)

By STEPHEN MACKENZIE, M.D., F.R.C.P.Lond.,
Senior Assistant Physician and Physician in charge of Department for
Skin Diseases, London Hospital, &c.

THE patient is a married woman, æt. 40, who had never had any important illness till three years ago, when she apparently had syphilis. She came under care for a tertiary syphilide, and during examination it was discovered that she had several subcutaneous nodules. In all, eight have been detected, which vary in size from a hemp seed to a split pea. The skin over them is natural, and they are all movable. They cause no pain, except when pressure is made on them. Two are situated along the posterior border of the ulna, and the remainder, with the exception of one in the gluteal subcutaneous tissue, beneath the skin of the thumbs and fingers.

(a) Abstract of paper read before the Clinical Society of London, April 27th, 1883.

The first she noticed about two years ago, and it has increased in size. None that she has observed have disappeared. As regards rheumatism, the only symptoms which could be in any way construed as due to this disease were some pains in the legs eight years previously, for which she used a liniment. She has never had chorea. There is no evidence of heart disease, nor of arthritis, present or past. The physical characters of the subcutaneous nodules are exactly those of the nodules described by Drs. Barlow and Warner in connection with rheumatism and allied affections. The interest in the case lies in the very indefinite, if at all existing, connection between the nodules and rheumatism. The patient had not suffered from any distinct rheumatic symptoms, nor is there any family tendency to that affection. The association of the nodules with the syphiloderm may be fortuitous. The duration of one of the nodules is greater than in any of the series of cases recorded by Drs. Barlow and Warner. The longest time they noticed nodules to persist without diminution was five months.

Clinical Records.

ST. VINCENT'S HOSPITAL, DUBLIN.

DR. MAPOTHER'S WARDS.

Tetanus—Exciting Cause doubtful—Recovery.

Reported by Mr. CORNELIUS KELLY.

J. McD., a tall, muscular corn-porter, æt. 22, on 23rd of February, suffered a severe strain in the back in lifting a great weight. To dull the pain he drank heavily, and during the ensuing night he lay stripped on the outside of his bed. On March 1st tetanus began, and he was admitted on the 6th. There was marked risus sardonius on the right, and a much lesser degree on the left, side of face, trismus which allowed the incisors apart for about one-third of an inch; severe opisthotonos and extreme epigastric pain. He had got some relief by lying on his front. Constipation was not throughout a pressing symptom, and the bladder gave no trouble. On the 10th day life was threatened by accumulation of pulmonary mucus. Some of the most severe fits of spasm occurred on the 23rd day, and the last, also very severe, took place on the 32nd. Subsequently he was well, with the exception of slight stiffness of the limbs.

The treatment adopted was 5 grains of chloral, and 10 of bromide of ammonium every hour he was awake. From the 8th day these drugs were only given in one dose at night. Free nourishment with strong beef extract and beaten egg with whisky. Quinine in 5 grain doses thrice daily was begun on the 8th day. External warmth.

Amongst clinical remarks it was noted that the patient's brother, a fine lad of 17, had been lately treated for excessive chorea. In tropical countries, strains and contusions are frequent exciting causes, and Rosenthal ignores idiopathic tetanus, asserting that some local lesion may always be found. Injuries to organs in which sympathetic nerves abound more than cerebro-spinal rarely excite tetanus; there was, however, in the obstetric wards at the same time an unmarried woman, æt. 50, who was seized with the disease seven days after the removal of a uterine polypus by the écraseur. The spasms did not extend beyond the head and neck. The same treatment was adopted, with the result only of lessening suffering, for death occurred on the 6th day. Great external warmth, and small frequent doses of alcohol were enjoined for the purpose of aiding free arterial supply to the muscles. That such was wanting in tetanus might be inferred from the induction of spasm in the allied malady, tetany, by pressure on the main artery of the limb (Trousseau's symptom), from Liston's observation that during amputation of a tetanised limb, the cut arteries did not project a drop of blood, and from the controlling effects of belladonna and calabar bean, which were vaso-motor depressants. The Turkish bath was an agent worthy of trial.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

GASTROSTOMY.—M. Tillaux entertained the Société de Chirurgie with an account of an operation which he practised lately at the Hôpital Beaujon, and which for its variety merits more than a passing notice. The operation, which was that of gastrostomy, was performed for an obstinate stricture of the œsophagus. The patient, a man of fifty-two, presented himself at the hospital complaining of difficulty in swallowing. On being interrogated, he declared that the pain commenced when the food was about midway in the œsophagus. A few days' treatment with the sound produced a good amelioration, and the man left the hospital. A year after he returned, looking very pale and dejected, and utterly unable to swallow. The sound refused to pass the stricture, even one of the smallest size, and the patient having demanded relief at any price, M. Tillaux decided on making an artificial mouth in the epigastrium. An incision was made parallel to the border of the false ribs on the left side, and the peritoneum having been reached, it was cut through, when the anterior wall of the stomach came to view, and was drawn forward, slit for a certain distance, and then attached to the external wound by seventeen sutures. The immediate results were satisfactory. On the fifth day the patient got up, and the strength was returning rapidly, when, on the fifteenth day, the man from some unexplained motive refused to allow any more food to be introduced into the stomach by the aperture, and he succumbed two days afterwards. M. Tillaux believed that, were it not for the obstinacy of the man, he would have lived a considerable time. The autopsy showed that the operation was fully warranted. M. Berger has also practised (last month) a similar operation, but, unfortunately, the necessity for the operation did not arise from a fibrous stricture of the œsophagus, but from cancer, and the patient died a few hours afterwards. M. Sée observed that actually he is attending a woman upon whom a Vienna surgeon had made an artificial mouth in the month of November last; further, before the gastrostomy, tracheotomy had to be performed, so that she is actually wearing two tubes, one in the trachea and the other in the stomach. At present she was regaining strength and getting fat. The operator had a method of his own which succeeds very well: he first makes the incision of the abdominal wall, and then leaves the patient quiet for eight days, at the end of which time he opens the stomach by means of the thermo-cautery. No chloroform is given, and the patient is standing up during the operation.

GLYCERINE.—Glycerine for a long time has been almost exclusively used in surgery for dressing wounds, in the treatment of cutaneous diseases, eye diseases, those of the ears, mouth, and nose, in some affections of the genito-urinary organs, and as an excipient in a great number of medicines. To Démarquay, in France, is due the credit of introducing it to medical practice. However, before the publication of the work of Démarquay, another had made experiments with it in gastro-intestinal affections with most satisfactory results, and its marvellous effect upon bleeding piles and fissures of the rectum is now well known. Recently M. Jaccoud and M. Ferrand have been trying it as a substitute for cod-liver oil in phthisis, and with so much success that the former orders it in every case where the oil is not borne, and under its use the patients increase in weight, the cough diminishes, and the dyspœnia is in many instances considerably ameliorated.

BORIC ACID IN TREATMENT OF CYSTITIS.—Boric acid as an antiseptic is eminently preferable to phenic acid in the

treatment of cystitis; and as to blennorrhagia, injections of a five per cent. solution have been followed by cure complete in less than a week. In the former affection injections of a three per cent. solution have been attended with the happiest results. The frequency of micturition is greatly lessened by its use, and the urine becomes quite clear and limpid. A pomade of boric acid is almost a specific for the erythema of infants.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 27TH.

The President, ANDREW CLARK, M.D., in the Chair.

DR. W. J. TYSON ON

A CASE OF LEPRA TUBERCULOSA.

R. C. S., æt. 16, was born in Ireland, and when two months old went to India, and remained there until he was six, then returned to Ireland, and has not been abroad since. His family history gives us no clue to his case. Was quite well until two years ago, when present condition of face first began to show itself. *Present Condition.*—Is physically strong and fairly well made, height 4 ft. 8½ in., his hair is reddish and his eyes are blue. Mentally does not seem dull. The appearance of the face is characteristic of the disease, and has, which many do, a somewhat lion like appearance; the skin is soft to the feel, thickened and of a brownish red colour; on his chin and just underneath it are about a dozen small elevations (tubercles) varying in size from a mustard seed to a pea. On the trunk in front and behind there is a yellowish-brown mottling. The chest and abdomen are healthy, no albumen in urine. Just below right buttock there is a patch of flattened tubercles, and over left olecranon a softish mass of the size of half a walnut. The hands are generally cold and the skin of each is thickened; around each wrist joint there are a few tubercles; skin over feet is red, thickened and scale-like in appearance. All joints are sound. The voice is hoarse, but this has only existed quite recently. There is no anaesthesia of skin. His diet does not seem to have been abnormal.

In reply to the President, the reader of the paper said that he had not been able to trace any history of nervous disturbance in the case.

Dr. SOUTHEY observed that the case was one of great interest. The boy presented the general tubercular nodules with thickening of the skin over the wrist usually associated with this form of leprosy. Two or three years later he would be found to lose sensation at the tops of his fingers; the digits would become immobile and less flexible, and it was not uncommon, as he himself had observed, for such patients at this stage of the disease to mutilate themselves by cutting off their fingers, owing to the little sense of feeling in them. Such a form of leprosy should be distinguished from anaesthetic leprosy, in which red and thickened patches of skin were observed, the insensibility commencing at the centre and proceeding peripherally to gradually greater and greater extent. This form never resembled tubercular leprosy, nor were its sequelæ so regularly manifested. Albuminuria in the latter form was sequential to the changes denoted as occurring in the fingers, and afforded indication of granular degeneration of the kidneys.

Mr. JAMES STARTIN drew attention to the presence of slight ulceration at the edge of the ears in Mr. Tyson's patient, and remarked that any information as to syphilis or diet in connection with the case would be of interest. The thickening of the ulnar nerve found in the case was commonly seen in the subjects of the disease. He had seen a patient so afflicted after ten years residence in India.

The PRESIDENT inquired if any search for bacilli had been instituted by Dr. Tyson.

Dr. SOUTHEY further asked if frequent micturition had been a symptom of the case, and explained that he ascribed the existence of granular kidney to a prevalent development of intercellular tissue in the body of the patient.

Dr. DYOR DUCKWORTH remarked on a similar case.

Dr. TYSON expressed great doubt as to being able to find

out any further details of the history of the case. He did not regard the slight ulceration of the ear adverted to by Mr. Startin as of any significance; such ulceration in this situation was common among children. He had not himself noticed the thickening of the ulnar nerve, nor had he made any investigation in respect to bacillus. Frequent micturition had not been noticed as a feature of the case.

On the motion of Dr. Andrew Clark, Drs. Southey, Thin, Dyce Duckworth, and Tyson were nominated a committee to inquire into the presence of, or absence of, bacilli in this case.

Mr. RICHARD BARWELL on

A CASE OF REMOVING A LARGE PORTION OF THE UPPER LIP WITHOUT DEFORMING THE FACE.

George S., *et. 61*, much addicted to smoking short clay pipes, came under Mr. Barwell's care with that singularly-rare disease, epithelioma of the upper lip. The growth was close to the corner of the mouth, but did not involve the commissure; and was so extensive that at least two-thirds of the lateral half of the lip would have to be removed in eradicating the disease. Such extensive excision must have disfigured the man very considerably unless means of prevention had been adopted. The following operation was devised and performed, 4th November, 1882: The base line of the triangle requiring removal was measured, and an equal line marked by a superficial incision extending from the corner of the mouth directly outward. The other sides of the triangle, also measured, were similarly traced from this line downward towards the ramus of the jaw. Thus was traced outside and below the mouth a triangular space exactly like that to be removed from the upper lip, but reversed. The first—the horizontal—incision was now deepened down to, but not into, the mucous membrane; then the two lateral limbs of the triangle were incised through all tissues into the mouth, and some bleeding vessels were twisted. The thick tissues of the flap were dissected from the mucous membrane, left hanging to the horizontal incision, to which, the extreme point being sacrificed, it was stitched, thus giving to that part a red border. The next step was the excision of the epithelioma along the lines already traced and measured. The edges of the lower of what may be called the complementary triangle were now brought together with twisted suture. In doing this it is to be noted that the horizontal base line of the complementary triangle was necessarily shifted inwards, and coming to lie above the lower lip took the place of that part of the upper lip which had been removed with the cancer. The new red border, made by turning up the mucous membrane of the cheek, imitated the natural red of the lip. The edges of the wound in the upper lip were now brought together with hare-lip pins, and the new mucous edging sewn with horse-hair, both to where it joined the old and at the commissure of the mouth. When all was complete, no deformity was left. The man recovered rapidly; and when seen two months after operation his mouth was as nearly perfect in form as previous to operation, nor did its movements appear in any way irregular or constrained.

Dr. ANDREW CLARK suggested the possibility that the appearance of cancer in the lower lip after the operation was due to the irritation induced, and which he said might be taken as an instance of successful triumph of growth over development.

Dr. SOUTHEY on

A CASE OF TACHETIC SYMMETRICAL GANGRENE.

Frank Nash, *et. 9* (admitted into Matthew Ward, St. Bartholomew's Hospital, November 25, 1881), was much emaciated, his hair thin and falling off, abdomen empty and retracted; skin dry, and he was in a curious, excitable, semi-delirious mental state. He presented a gangrene of the tip of his right index finger, all his extremities felt cold, and he had insomnia. His pulse was 143, very feeble. Respiration 32. Temperature 99°. His heart beat with feeble impulse in normal situation. There was no increase of normal cardiac dulness; no cardiac murmur; no physical signs of lung disease. Neither liver nor spleen transcended its normal limits. His appetite was bad; he had had no sickness; bowels acted once daily; tongue clear and moist; micturition gave no pain; urine scanty, not abnormal; chiefly passed with his stools. *Course and Progress.*—After a few days the thumb and second finger of the same (right) hand were

similarly involved, became first red and throbbled, then livid, and finally gangrened. On December 5th, an exactly similar spot occurred on the pinna of the right ear, and on the extremity of his nose, and the tip of the middle finger of his right hand. A little later, subcutaneous mottlings (*tachetés*) appeared all over his trunk and limbs, and developed into a raised rash, like urticaria tuberosa, or erythema tuberculatum. The spots first itched, then became painful and tender, but gradually subsided, leaving only some pigmentation to mark their sites. Finally, all the fingers and thumb of the right hand gangrened and slowly separated, and the thumb, index, and little finger of the left hand. He passed into a condition of most extreme prostration, with broncho-pneumonia of both lungs, and only very slowly and gradually recovered from it. In January, 1882, a new and interesting clinical feature was manifested, namely, intermittent true hæmaturia, bloody urine being passed alternately with normal-coloured, non-albuminous urine. Some days distinct blood cells were passed with the urine; on others, blood colouring matter without blood cells; on others, albumen with blood enough to give the blood reaction only. Oxalate crystals were present in great abundance when the hæmaturia was abundant, and *vice versa*. No tube casts were ever noticed. All symptoms of urinary disorder disappeared in July, 1882, when the child was discharged well, but with the loss of his fingers. He has been seen several times since. The author next cites some parallel examples of this malady, which he refers to vaso-motor disturbance.

Dr. ANDREW CLARK asked if any history of rheumatic gout could be traced in this case? He was familiar with such forms of gangrene in this connection.

Dr. SOUTHEY said he knew of nothing in the history to justify him in an affirmative reply, and referred to the account of a very similar case to his own, published in 1804 from the pen of a French physician—Raynaud.

Dr. BARLOW said he had never seen so severe a case of the disease as that described by Dr. Southey, but he had seen several which were less severe. As Dr. Southey had observed, the most important feature they presented was not the gangrene, but the vaso-motor disturbances. In one case, within his own experience—that of a man, *et. 35*, who had been generally regarded as rheumatic—the attacks, which usually occurred during winter, were ushered in by pain in the extremities, which was followed by the appearance of bluish red patches on the integuments. When first seen by Dr. Barlow, he had just suffered an attack, and there was a distinct patch on one trochanter, while one toe was the subject of local gangrene. In two other cases observed, in female children, 3½ years old, the attacks occurred between September and April, being rare in summer, and were in the latter case associated with sudden changes in temperature. In one child the lower limb affected was black from above the ankle to the toes when seen, and presented a most alarming appearance. It remained thus for about three hours, and then passed off, the child seeming quite well again. The attacks occurred on cold days in the other case also, and on several occasions were accompanied with violent stomach-ache, while two or three hours subsequently dark-coloured urine, containing hæmatin, oxalate crystals, and albumen, would be passed, but only once after each attack. Dr. Barlow considered that the disease presented many points in common with that known as paroxysmal hæmaturia. It was a disease of winter, and was usually preceded by a condition of sleepiness; its resemblance to ague attacks was not well marked, for there was no sweating stage observable, the cold stage being the principal one. He had elicited from the mother of the patient presenting typical paroxysmal hæmaturia that the child's finger ends grew distinctly blue during the attack, and so familiar was the appearance that no heed was paid to it especially. Dr. Barlow quite agreed that application of cold was a more rational treatment than the employment of warmth, being led to this opinion from his knowledge of the effects produced by cold in the treatment of frost-bites. He mentioned the case of a child which, a sufferer from paroxysmal hæmaturia, and accustomed to be washed in warm water, was submitted to the influence of cold water, with good results. The constant current applied down the back had been employed by Raynaud, with a view to diminish the irritability of the vaso-motor centres, and with success. A patient of his own had described how this treatment had done him much good while in St. Bartholomew's Hospital, and the method was

certainly worthy of extended trial. There was no confirmation forthcoming of the association of rheumatic gout with the disease. Mr. HUTCHINSON, however, had described a connection between end-joint arthritis and Raynaud's disease, and a patient under his (Dr. Barlow's) care might be taken to confirm this opinion.

Mr. CRIPPS took exception to the definition of Dr. Southey when calling the affection a "blood" disease. He, himself, regarded it as an essentially local complaint, and the gangrene as its principal feature. Such cases were analogous to frost-bite, to the production of which no special bodily condition was necessary, but simply exposure. Children who were attacked by symmetrical gangrene would be found to have suffered from chilblains, which were an indication of enfeebled circulation dependent on a weak heart. He cited the case of a young woman who had been affected with chilblains, and who being suddenly in reduced circumstances, gave birth to a child, after which event she developed symmetrical gangrene, with the result that she lost both lower extremities. He did not agree that it was right to apply cold or evaporating lotions to gangrened limbs. Brodie's treatment, by wrapping the limb in cotton wool and keeping it covered was wiser. Opium was the most reliable drug to employ.

Dr. BARLOW pointed out that he had not recommended the application of cold in the treatment of gangrene.

Dr. MAHONEY had seen two cases similar to that mentioned by Dr. Southey. In one intermittent hæmatinuria had existed, and crystals of oxalates were found in the urine. He explained that this frequent association of intermittent hæmatinuria with symmetrical gangrene effectually separated such cases from those dwelt on by Mr. Cripps, and moreover, the patients in those cases were not necessarily endowed with a feeble circulatory apparatus. A female patient of his own had suffered from the disease in a more or less chronic form for seven or eight years. The fingers presented a gangrenous appearance, which varied with the weather, but was not improved by treatment. The tips of two or three fingers had been quite lost. In summer time the hand was quite useful.

Mr. SYMONS referred to several cases within his own experience which possessed features having resemblance with those previously discussed.

Dr. SOUTHEY accepted Mr. Cripps's correction of the term "blood disease," and substituted for it the description of a general disease with local manifestation. Raynaud's account of it as being a vaso-motor disturbance was probably accurate, but the ætiology was very obscure. As a rule, local asphyxia was the final stage arrived at as the result of the disease, the tendency to go on to gangrene being unusual. In one case, that of a woman, three fingers were seen, on two separate occasions, to become quite purple, and even during observation, colour and sensibility were restored.

With the consent of the respective authors, the two following papers were taken as read:—

Dr. STEPHEN MACKENZIE ON

A CASE OF SUBCUTANEOUS NODULES OCCURRING IN A PATIENT THE SUBJECT OF SYPHILIS, AND WITH VERY INDEFINITE CONNECTION WITH RHEUMATISM,

which will be found on page 378; and

Dr. DYCE DUCKWORTH ON

A CASE OF RHEUMATISMAL, CUTANEOUS, SUBCUTANEOUS, AND PERIOSTEAL NODULES,

which will be found on page 377.

The following living cases were shown:—Spondylitis deformans; Tubercular ulceration of hard palate; Tubercular leprosy; Rheumatismal nodes.

ACADEMY OF MEDICINE IN IRELAND.

PATHOLOGICAL SECTION.

A MEETING of the Pathological Section of the Academy of Medicine in Ireland was held on Friday evening, April 6, in the Albert Hall, Royal College of Surgeons. Dr. PURSER, Sectional President, in the chair.

Mr. BENNETT, Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

SPECIMENS EXHIBITED BY CARD.

Mr. P. S. ABRAHAM—Colloid-like bodies in the medulla and cerebellum, from a case of diabetes.

Surgeon Major HAMILTON—Three specimens of typhoid lesions; ulcers in the ileum.

Mr. THOMSON—Multiple fractures of the lower jaw.

Dr. WALTER SMITH—Abdominal aneurism.

Dr. PURSER—Atheroma of aorta; endarteritis deformans.

Mr. J. DAVISON and Mr. P. S. ABRAHAM—Bones of young lower animals after fracture, showing increase in size.

Dr. J. M. REDMOND—Spontaneous aneurism of the brachial artery; heart showing deposit on aortic valves.

HEMATERPHIA FACIALIS.

Mr. JOHN B. STORY exhibited a young man, æt. 21, suffering from this deformity upon the right side. The patient's mother stated that the defect was congenital, and had been caused by a fright early in her pregnancy from a guinea pig being thrust into her face. In favour of this theory there was undoubtedly congenital deformity of the right auricle on the same side. In the autopsy, all the tissues, skin, muscle, and bones were involved, the skin atrophy being best marked over the eyebrow; and of the bones the superior and inferior maxilla being most implicated.

Dr. McSWINEY asked whether the man was idiotic, or whether he had been delivered at his birth with forceps; and Mr. Story replied in the negative to both questions.

ABDOMINAL ANEURISM.

Dr. WALTER SMITH exhibited an abdominal aneurism taken from a man, æt. 38, who died on the 10th ult. The immediate cause of death was an acute pleuro-pneumonia of the right side. The aneurismal symptoms first declared themselves about two years and three months before his death, by pains in the back, which gradually increased in severity until he was obliged to give up work and seek admission to hospital. Below the ensiform cartilage could be seen and felt a tremulous pulsation, attended with a loud systolic murmur, audible as low as the umbilicus, and posteriorly along the spine from 8th dorsal to 2nd lumbar vertebrae. In December last an eccentric impulse was detected under the 12th rib on left side, and about the middle of February he was seized with intense pain in the right hip, thigh, and leg, and from that date he rapidly sank. The autopsy showed that the right lung was consolidated; weight, 3lbs. 10oz.; abundant flaky lymph on pleura. The left lung was healthy; weight, 1lb. 12oz. A large sacular aneurism sprung immediately below the diaphragm, and extended to within an inch of the bifurcation of the aorta, and laterally from one kidney to the other. Extensive erosion of 11th and 12th dorsal vertebrae; and 1st lumbar vertebra; 11th and 12th ribs on left side detached from spine and adherent to the sac. The sheath of right psoas muscle was the seat of a large fusiform diffuse aneurism, communicating freely with the main sac. Abdominal viscera healthy.

Dr. H. KENNEDY remarked on the exceptional mode of death in this case, and discussed the diagnosis of aneurism of the abdominal aorta and cancer; and Dr. Smith replied.

DYSIDROSIS.

Mr. CORLEY read a paper on the disease to which Tilbury Fox applied this name, and which Mr. Jonathan Hutchinson termed cheiro-pompholyx. He detailed the history of two cases, both following injury of the median nerve, and in one of which, after the eruption had disappeared from the hand of the injured side, a similar eruption broke out on the opposite hand. This, he considered, indicated that the irritation produced in the member first affected was propagated to the spinal cord, and produced there a nervous disturbance which passed across and down the nerves of the opposite limb. From the consideration of these cases, as well as those detailed by Hutchinson and Fox, Mr. Corley was of opinion that the disease was genuine herpes zoster of the hand, due to either centric nervous disturbance or irritation of nerve trunks, and he therefore rejected the name and pathology suggested by Tilbury Fox.

Dr. WALTER SMITH discussed this communication, and illustrated his remarks by the facts of a case recently observed by himself, and Mr. Corley replied.

ATHEROMA OF THE BRANCHES OF THE PULMONARY ARTERY.

Dr. PURSER showed an example of extensive atheroma of the branches of the pulmonary artery. The primary trunk was free from disease, but the smaller divisions of the vessel were much affected. The aorta was healthy. The right ventricle was greatly hypertrophied, without much dilatation. There was chronic pneumonia of both lungs. The patient was a middle-aged woman who died almost imme-

diately after her admission into hospital before any history could be obtained.

The Section adjourned.

THE GENERAL MEDICAL COUNCIL.

In our last we reported the first three days' sittings of the Council. We now proceed to give a brief *résumé* of the remainder of the session, from Monday to Thursday last week. The meetings were resumed as usual, under the Presidency of Dr. Acland, at 2 p.m. on Monday. A new member was introduced at this sitting, in the person of Dr. Matthews Duncan, *vice* Sir William Gull, resigned.

MONDAY, APRIL 23.

REPORT OF PHARMACOPŒIA COMMITTEE.

On the motion of Dr. QUAIN, seconded by Dr. AQUILLA SMITH, it was resolved that the report of the Pharmacopœia Committee be adopted, with the addition, after the figures £800 (see page 837, column 2, line 4), of the words "for which they now ask the sanction of the Council."

THE FINANCES OF THE COUNCIL.

The following report of the Finance Committee was presented and adopted:—The income of the General and Branch Councils for the year 1882 (ending January 1st, 1883) was £7,164 7s. 11d., which exceeds by £655 the income for the year 1881. The expenditure during 1882 had been £4,820 10s. 1d., which was above the expenditure of 1881 by £33 16s. 1d. The committee had, however, the satisfaction of reporting to the Council that the excess of income over expenditure for the year 1882 amounted to £2,343 17s. 10d. The principal item of diminished expenditure for the year 1882, as compared with 1881, was in the visitation of examinations. The sum contributed in 1882 to complete the amount expended on the visitation of examinations was £467 10s. 9d., as compared with a sum of £920 19s. 6d. expended in 1881 on this visitation. The late visitation of examinations had now cost a total sum of £1,388 10s. 3d. In the receipts for the year ending January 1st, 1883, of the Dental Registration Fund, £718 7s. 5d., there was an increase of only £27 11s. 3d. over those of 1881; while the expenditure, £1,227 18s. 10d., had been greater by the sum of £129 11s. 7d., attributable to its share of the increased expenses of General Council's session, leaving the deficiency of income for the year £506 2s. 1d., compared with a deficiency of £457 11s. 1d. in 1881. Pursuant to instructions given to them at the meeting of the English Branch Council in 1883, the treasurers had made an additional purchase of £1,500 Consols, in the names of the trustees of the Branch Council, thus making a total now invested under this trust of £30,500 Consols. During the year, also, a sum of £1,200 had been invested by the Scottish Branch Council, making a total investment of £3,200; and the Irish Branch Council had increased its investments by £150, bringing up its total under this head to £1,869 17s. Thus the total amount now invested by the three Branch Councils was £35,569 17s.

THE MEDICAL ACTS AMENDMENT BILL.

Mr. MACNAMARA, in introducing the resolution of which he had given notice, said that he considered it his duty to bring under the notice of the Council some points in the Bill now before Parliament. He was one of those who entertained a conviction that the Council would be abrogating its functions, and justifying all the adverse remarks that had been made regarding it, if the members shrank from considering certain portions of the Bill. The Bill involved two classes of principles—those having reference to the construction of the Council, and those referring to changes in education and examination. He thought it would be beneath the dignity of the Council to discuss the question of its reconstruction. He thought it highly desirable that legislation on medical reform

should be carried out, and that attempts at improvement in education should not be constantly paralysed by legislative alarms. That the Bill contained some matter that was good and some that was dangerous could not be gained. One thing was clear. If the Bill passed, the power of conferring degrees and licences entitling to registration would be removed from the corporations, whose direct breadwinning function would thus be obliterated. It was the duty of the Council to suggest improvements in the Bill; and Mr. Macnamara proceeded to give in detail the amendments which he considered necessary, and concluded by moving, "That the Council resolve itself into a committee of the whole Council for the consideration of the provisions of the Medical Act Amendment Bill as amended and ordered to be printed on April 10th, 1883."

Mr. COLLINS seconded the motion.

Dr. AQUILLA SMITH supported the motion. There were some clauses in the Bill with regard to which the Council should express an opinion. If the Council allowed the Bill to pass *sub silentio*, there was danger that it would be inferred that they had no just grounds for objection to any part of it.

Dr. HUMPHRY said that to consider the Bill in committee would occupy a great deal of time, and he doubted whether it would do any good. He feared, indeed, that more harm than good might be done.

Dr. HALDANE, Dr. PETTIGREW, Dr. HERON WATSON, and Dr. LYONS supported the proposal to discuss the Bill, and Mr. SIMON opposed it. Mr. MACNAMARA having replied, and the PRESIDENT having stated that he could not support the proposal, the motion was put to the vote, and the votes for and against being equal, it was not carried and the discussion of the proposed Government measure was therefore abandoned.

DR. JACOB'S LETTER ON THE ATTENDANCE ON LECTURES BY MEDICAL STUDENTS IN IRELAND.

A communication addressed to the Registrar by Dr. A. H. Jacob, of Dublin, was next read, of which the following are the principal points:—

"SIR,—Since the last meeting of the General Medical Council, circumstances have arisen which induce me to call attention to practices prevalent in Dublin, which, I believe, are in the nature of an evasion of the requirements of the Council, in regard to the duration and scope of medical study.

"It is probably within your recollection that on the 18th of July, 1879, the Rev. Dr. Haughton moved 'That the Council do . . . inquire what precautions are taken . . . to secure that the certificates . . . guarantee . . . attendance on the part of the holders on lectures, dissections, laboratory work, and hospital work, and are not merely receipts for money paid.' In the debate upon this motion Dr. Haughton is reported to have said: 'It has come to my knowledge that certificates have been issued in cases in which there has been no attendance at all.' On the succeeding day, July 19th, 1879, it was resolved by the Council 'That the Branch Council for Ireland have its attention drawn to the foregoing statement, and that they be requested to inquire . . . and report thereon to the Council at its next meeting.

"The report of the Branch Council for Ireland was presented on July 16th, 1880. It laid before the Council, *in extenso*, the replies of six Dublin medical schools, and ten Dublin clinical hospitals, to the question: 'What precautions have been adopted to ensure the *bonâ fides* of the certificates issued by them to their several students?' but it expressed no opinion, and offered no recommendation thereon, and the Council does not seem to have taken any further action in the matter. . . .

"As a matter of fact, I am in a position to assert that the statement of the Rev. Dr. Haughton, above referred to, was true to the fullest extent, and that it is notorious that in Dublin certificates of 'diligent' attendance could be obtained, and were obtained in any number, from certain schools and hospitals by payment of the fee, and without any real attendance, for confirmation of which statement I beg to refer you to second paragraph of a letter from Carmichael College, and to the fact that the Rev. Dr. Haughton—in his capacity of Medical Registrar of Dublin University

— had, in consequence of these practices, refused, for some years, to recognise the certificates issued by a certain Dublin medical school.

“These practices it is difficult for any licensing body to prevent, because it usually possesses no information respecting the circumstances under which the certificates presented by any individual candidate for its licence are granted to him. Two years ago, however, positive proofs came into my possession that several persons had passed one or other of the examinations of the Royal College of Surgeons in Ireland, to which they had been admitted on production of all the requisite certificates of ‘diligent’ attendance at lectures, dissections, and hospital, they being, in fact, so circumstanced that attendance on any material portion of these courses was physically impossible, inasmuch as they were engaged from morning to evening, for every working day of the medical session, in offices, banks, and shops.

“About this period, the Ledwich School and Carmichael College (the latter of which immediately afterwards discontinued the practice) commenced to advertise that they would provide lectures from 7 p.m. to 10 p.m. in the evening, such instruction being available for clerks, shop assistants, and other students whose entire day was employed in engrossing business avocations, and the Council of the Royal College of Surgeons, having protested against this system, and communicated its protest to the General Medical Council, eventually adopted a code of regulations for the specific certifying of attendances, and passed an ordinance refusing to receive the certificates of any school which gave lectures at night.

“The promulgation of these resolutions by the Royal College of Surgeons disclosed the extent to which fictitious certificates were in use, for no fewer than 94 students, who were stated by their representatives to be all so engaged as to be unable to attend medical study during the day, presented a memorial to the College demanding that the resolution of the Council should be rescinded. I have no reason to suppose that the issue of fictitious certificates has been to any extent discontinued, except with regard to those students who intend to seek their qualifications from the Irish College of Surgeons or Dublin University.

“That the certificates issued in respect of medical study limited to the evening hours must, in many cases, be fictitious, will be manifest on consideration of the hours set apart in all Dublin schools and hospitals for medical instruction. Hospital *clinique* begins about 9.20 a.m., and goes on continuously until after 11 a.m.; operations are performed, and clinical lectures delivered, usually from 10.30 a.m. to 11.30; and the extern department is visited, case-dressing performed, and autopsies made from 11.30 to 1 p.m. It is hardly necessary for me to ask, of what educational value are the certificates of ‘diligent’ attendance on this daily work presented by a student who may, possibly, have written his name in the attendance book at 9.15 a.m., but who must be at his business in office or shop before 10 a.m., at the latest. Again, I would point out that it is hardly physically possible for a student, after the closing hour of his place of business, and allowing time for his evening meal, to give, within three *Anni Medici*, an attendance for an hour each upon the minimum number of lectures required for his licence, even if his attendance upon special studies, his instruction in vaccination, his private teaching, and his reading are omitted from the calculation. . . .

“I therefore respectfully invite the Council to declare that the issue of fictitious certificates is not tolerated by it, and that a nominal attendance, at night, upon the course of medical study, by students who are engaged all day at other engrossing avocations, is an evasion and not a compliance with the recommendation of the Council, which declares, ‘The course of professional study . . . shall occupy four years . . . passed at a recognised school. . . .’”

Mr. MACNAMARA said that in Dublin hospital work was conducted from 9 to 10 a.m., and at 10 a.m. operations were performed. The object was to do the hospital work early, so as to enable the students to proceed to the anatomical hall at 11, and then to the lectures, which went on from 1 to 5 p.m. The gentlemen referred to in Dr. Jacob’s letter were engaged during the day as clerks in banks and other houses of business. The College of Surgeons of Ireland had refused the certificates of several of these candidates; but they were admitted elsewhere, and the only result was a loss to the College. Each professor and lecturer certified for his own class.

The great majority of pupils went first to the College of Surgeons, and afterwards to the College of Physicians. The University of Dublin had tried in every way to secure the attendance of students; but some classes were very large, and it was difficult to ascertain the attendance accurately.

Dr. CHAMBERS said that there was another class of students who, being employed in the day, attended evening lectures: he referred to unqualified assistants. He had known a case in which one of these passed a preliminary examination, continued to act as an unqualified assistant, got some one to instruct him, went to another part of the kingdom, got his schedule signed, and obtained a diploma.

Dr. SMITH said there was a school in Dublin in which it had long been the practice to sign the sheet of attendance at the end of the session without due inquiry.

Mr. SIMON said the question was a very important one. It was, whether it was not a substantially fictitious studentship, when a man, pretending to be a student, was engaged in another career. There might be individual instances in which a man, by long study and distinguished ability, might obtain the necessary knowledge while engaged in other occupations; but the meaning of the recommendations of the Council respecting four years of study was plainly that, during that time, such professional study should be the real occupation of the student. He moved:

“That for the purposes of the Council’s Recommendation 21, and of regulations by which the licensing authorities may desire to give effect to it, the ‘four years’ required to be spent in professional study must be four years during which professional study shall have been adequately followed by the candidate as his true industry and the main-occupation of his time, and that the Council would not be prepared to count as part of their four years’ curriculum any considerable time during which a candidate had given most of his industry to other pursuits, as, for instance, if he had been regularly engaged for the greater part of each day in the duties of some non-medical calling followed by him for a livelihood.”

Dr. QUAIN seconded the motion, the further consideration of which was adjourned.

FIFTH DAY.—TUESDAY, APRIL 24.

FALSE DEATH CERTIFICATES.

THE solicitor to the Council reported a complaint from the Medical Alliance, in which a medical practitioner named Gray was stated to have issued a death certificate in respect to a child whom he had not seen prior to its decease. The same gentleman was further accused of having systematically followed the course complained of, but it had actually been brought home to him in only the one instance named, for which a fine of £5, and costs of two guineas, were exacted in the Thames Police-court. The real attendant in the case had been an unqualified assistant employed by Mr. Gray.

In defence of his conduct, Mr. Gray, through his solicitor, urged that the certificate was signed by his assistant “for Thomas Gray,” this assistant having been in his service ten years, and being thoroughly competent to undertake such duties as he discharged. Since March, 1882, Mr. Gray had refrained from giving such irregular certificates, and he now expressed regret for having done anything which brought him within danger of censure by the Council. He did not, however, regard his conduct as deserving of the title “infamous in a professional respect.”

Strangers having been directed to withdraw, the Council deliberated on the case in private, and the President subsequently announced that the following resolution had been come to as a result of the secret discussion:—

“That Mr. Thomas Gray having been convicted at the Thames Police-court of making a false certificate concerning the death of a child whom he had not seen, but who had been attended by his unqualified assistant, the Coun-

cil intimate to Mr. Gray their marked disapproval of his conduct, but in the exercise of their discretion do not think it necessary now to remove his name from the *Medical Register*."

THE CASE OF A. A. SADGROVE.

Consideration of the case of Mr. A. A. Sadgrove, which had been adjourned on the preceding Friday, and which is sufficiently detailed in our report of that day's proceedings, was next entered on, Mr. Sadgrove again appearing in person. He denied all knowledge of the letter previously referred to, and, having expressed contrition for his wrong-doing in laying claim to qualifications he did not possess, besought the mercy of the Council on the ground of his family's dependence on his efforts to support them.

After privately deliberating on the case, the Council arrived at the following resolutions, which were read from the chair:—

"(a) That Arthur Augustus Sadgrove, Lic. Apoth. Hall, Dublin, 1880, is judged, after due inquiry, to have been guilty of infamous conduct in a professional respect.

"(b) That, as it has been proved to the satisfaction of the General Medical Council that Arthur Augustus Sadgrove has been guilty of infamous conduct in a professional respect, the Council does, by this order in writing, direct his name to be erased from the *Medical Register*, and gives orders to the Registrar to erase his name accordingly."

On the motion of Dr. LYONS, seconded by Mr. TURNER, it was resolved further—

"That it be remitted to the Executive Committee to take such steps as may seem advisable to trace the letters signed 'A. Duncan' which have appeared in Mr. Sadgrove's case."

SIXTH DAY.—WEDNESDAY, APRIL 25.

DENTAL EXAMINATIONS WITHOUT CURRICULUM.

Dr. STORRAR moved, and Dr. FERGUS seconded: "That in the opinion of this Council the Examination in Dentistry *sine curriculo* should cease and determine after December 31, 1883."

To this an amendment was moved by Dr. HUMPHRY, and seconded by Mr. MARSHALL, to the following effect: "That in the opinion of this Council the Examinations in Dentistry *sine curriculo* should be limited to persons already on the *Dentist's Register*." After some discussion the amendment was carried, and becoming then the original motion was agreed to.

COURSE OF PROFESSIONAL STUDY.

The adjourned discussion on this subject held over from Tuesday was next proceeded with, Mr. SIMON moving, and Dr. QUAIN seconding: "That for the purpose of the Council's *Recommendation* 21, and of regulations by which the licensing authorities may desire to give effect to it, the 'four years' required to be spent in professional study shall have been adequately followed by the candidate, as his true industry and the main occupation of his time; and that, in the opinion of the Council, much caution ought to be used in admitting as part of the four years' curriculum any considerable time during which a candidate had given most of his industry to other pursuits, as, for instance, if he had been regularly engaged for the greater part of each day in the duties of some non-medical calling followed by him for his livelihood."

An amendment, proposed by Dr. MATTHEWS DUNCAN, and seconded by Mr. TURNER, was submitted, to the following effect:—"That the Council having had its attention drawn, by the letter of Dr. Jacob (pp. 118-121 of this Volume of *Minutes*), to the use of fictitious certificates, object in the strongest manner to their issue by teachers, and their use by candidates for licence. They recommend that no certificates be granted to a student who has been absent for more than one-fourth of the lectures required in any course, and direct that this be

added to the Council's 'Recommendations on Education and Examination.'"

After some time had been spent in discussion, both motion and amendment were by consent withdrawn.

Another case of false death certificate was investigated, and, after the usual private deliberation, the Council decided in respect of it:—"That Mr. William Henry Dry having been convicted at the Worship Street Police Court of making a false certificate concerning the death of Henry James Ault, a child whom he had not seen, but who had been attended by his unqualified assistant, the Council intimate to Mr. Dry their marked disapproval of his conduct, but, in the exercise of their discretion, do not think it necessary now to remove his name from the *Medical Register*."

DR. JACOB'S LETTER.

Mr. TURNER moved, and Mr. SIMON seconded:—"That Dr. Jacob's letter be referred to the Irish Branch Council for inquiry as they may find needful, and for report thereon."

This was agreed to.

The Executive Committee presented a report on the subject of personation, which merely intimated that they were at that stage of proceedings not in a position to report definitely on the matter to the Council.

Dr. AQUILLA SMITH moved, and Mr. MARSHALL seconded, and it was agreed to:—" (a) That the resolutions based on the report of the Committee on the Employment of Unqualified Assistants by Registered Practitioners, which were passed by the Medical Council on the 21st of April, 1883, be transmitted to the Lord President of the Privy Council.

"(b) That the resolution of the Council, marked (b) in the Minutes of April 21, 1883, be referred to the Executive Committee to communicate with the Registrar-General."

SEVENTH DAY.—THURSDAY, APRIL 26.

THE MEDICAL BILL.

Dr. HALDANE moved, and Dr. HERON WATSON seconded:

(a) "That the constitution of the Medical Board for Scotland, as laid down in Clause 9 of the Medical Act Amendment Bill (as amended in Committee), is unsatisfactory, and should be amended."

(b) "That the authorities should be directly represented in the Medical Council."

Dr. HALDANE pointed out that, if the Medical Bill became law it would be owing to the action of the Council. The power of closing schools and appointing examiners to be conferred on the Medical Boards made it imperative that their election should be of the most impartial character. After referring to the number and mode of election of members of the "Board," he pointed out that the Scotch Universities, being essentially great teaching bodies, were materially interested in attracting students. They were not, however, older tutorial institutions than the corporations, nor was the numerical preponderance of graduates over licentiates remarkable as regarded even single qualifications, while in the granting of double qualifications the corporations were in excess. Although graduates possessed a higher degree of scientific knowledge, they were no better informed than licentiates in the purely medical subjects. He felt that the final examinations were as searching in one case as in the other. He had no hesitation in asserting that the large preponderance, 8 to 3, given to Scotch Universities on the Board was designed to affect the Universities in favour of the Bill. By the influence of the Universities, the College of Physicians, when it obtained its charter, was forbidden to teach, and was compelled to admit every graduate of a Scotch University to its Licence on demand, a condition only removed twenty years ago. The appointment of external examiners by the Universities themselves was not calculated to obtain impartial selections, and worked detrimentally to students' interests. The passing of the Bill would lead to suppression of the Extra-Mural School of Medicine at Edinburgh, and so create a great and serious loss to students and to young medical men. Even now, many University professors felt and expressed a wish to establish the School; its loss would injure the University also. Without urging any special constitution of the Board, he

thought six University and eight Corporate representatives would be fair.

Dr. PYLE corrected a misstatement made by Dr. Haldane, to the effect that Durham University was not a teaching body.

Dr. PITMAN moved as an amendment, "that the Council do not express an opinion on the question." He did so in the wish to find out whether the Council was of opinion that it was wise to discuss questions which were not properly within its province. Dr. Haldane had not succeeded in altering the opinion he (Dr. Pitman) held on this question, for he had not objected to the medical boards, but only to the constitution of one of them, and that only on behalf of two corporations. By proceeding with the matter, the Council would really be deciding between the Corporations on one hand and the Universities on the other, as regarded Scotland. While admitting the right, he denied the propriety of discussing a Bill respecting which the opinion of the Council had not been asked—such action would even be impertinent. The Scotch bodies should have acted as did the English corporations, and laid their objections before the Lord President of the Council.

Prof. HUMPHREY seconded the amendment.

Mr. MACNAMARA felt it incumbent on himself to reply to Dr. Pitman, who had shown singular want of judgment in acting as he had done, a majority of the Council having already decided to discuss the Bill.

Mr. SIMON thought the Council would be quite consistent in agreeing to the amendment. It was enough to have heard Dr. Haldane's objections, and the Council would do well to refrain from voting on a matter about which no unanimity could prevail. The Council might well vote unanimously its hope that success in the best sense might attend the Bill.

Dr. AQUILLA SMITH said Dr. Haldane's suggestion respecting the reason for the preponderance of University representatives on the Scotch Board had struck him as remarkable, and its truth was confirmed by an examination of the constituent elements of the other boards. He imagined that the Council might discuss the principles of the Bill with propriety.

Dr. SCOTT ORE on behalf of the Faculty of Glasgow approved the main principles of the Bill, but objected to the preponderance of university representation on the Scotch Board. If carried out, such preponderance would in time effectually suppress the corporations. At Glasgow three distinct and separate extra-mural schools existed, with about forty teachers. It would be right to have the boards constituted as suggested, viz., universities six, corporations five.

Dr. MATTHEWS DUNCAN while admitting the importance of Dr. Haldane's views would still support Dr. Pitman's amendment. In the best interests of the Universities of Scotland he felt their preponderance on the Board would result in great injury to those bodies themselves.

Dr. STORRAR supported the amendment. Dr. Haldane had stated one side of the question; it was probable Lord Carlingford had acted as he had from knowledge in his possession, but even assuming the Government to be in error, it was impossible that the Council could influence the matter by its vote.

Mr. TURNER supported the amendment.

Dr. HERON WATSON insisted that as a Council of medical education and registration, it was incumbent on the Council to consider such questions as Dr. Haldane had introduced. He could not recognise any special feature in the constitution of Edinburgh University to entitle it to preponderance over Glasgow and St. Andrews in respect to representation on the Medical Board, but it might well be left to these bodies to fight out their differences on another platform than the Council. After sketching the history of the treatment of St. Andrews by its sister Universities, he said he could not admit any claim of Edinburgh, Aberdeen, and Glasgow to the preponderance given them on the Board. The evidence before the Royal Commission on the Medical Acts offered nothing to encourage the attacks made upon the Colleges of Physicians and Surgeons of Edinburgh; the action of these bodies had always been dignified and in the interest of the profession. They had also maintained a proper examination standard as shown by the tables of rejections of candidates at the tests of the Colleges, which had been admitted to be of a high character. In virtue of the power to be given to the medical boards, the Scotch Universities, if represented as proposed on the Scotch Board, would practically have in their power to utterly abolish the corporations in that division of the Kingdom; and in appeals to the Council the Universities, through their majority, would

necessarily enjoy a greater influence than the corporations. Dr. Watson concluded by reading extracts from the petitions presented against the Bill by the College of Surgeons of Edinburgh, &c., to show how the provisions of the Bill, unless modified, would tend to react injuriously to the interests of students and to the disadvantage of the profession of medicine.

Dr. HUMPHREY did not think the protesting colleges would be benefited by an expression of opinion on the point raised by the Council. It was no duty of the latter to discuss the comparative merits and interests of different bodies. It could not form an opinion, for instance, respecting the claims of the Edinburgh extra-mural schools. In any case, however, it would be improper for the Council to offer any opinion on the Bill in the absence of any invitation to do so from the authors of the measure.

Dr. PETTIGREW said he had heard, for the first time, on the preceding day, that it was suggested to give no place on the Scotch Medical Board to St. Andrews University. This body had suffered much injustice in the past, and it ought now to be reinstated to the position originally possessed by it. The examinations were all highly satisfactory, as was shown in the Commissioners' report.

Dr. HALDANE asked permission to withdraw his motion.

The PRESIDENT, in a few impressive words, urged the impropriety of the Council having entered on this question at all.

Mr. SIMON advised that Dr. Haldane should accept the amendment of Dr. Pitman, as this course would obviate a long discussion subsequently on the series of resolutions proposed on the Bill.

Dr. LYONS contended that a useful purpose had been served by the discussion which had taken place. He thought it would be wiser to press for leave to withdraw.

Leave having been given, the motion was withdrawn, and other motions standing in Dr. Watson's and Dr. Haldane's names were similarly treated.

Several notices of motion dealing with proposed amendments to the Medical Bill having severally been proposed and seconded, were, by permission, withdrawn.

Mr. MACNAMARA proposed the first of a series of eleven amendments to the Medical Bill, to the effect that in clause 3, page 1, line 19, should be inserted after "mentioned" the words, "and has been affiliated to, and obtained a medical diploma from, any medical authority under this Act." Affiliation, urged Mr. Macnamara, should be made a *sine qua non* of registration. Without the moral influence exercised by the corporations to which practitioners were attached, cases of infamous conduct would be much more common. Affiliation, also, would preserve the revenue of the corporations. He did not think that affiliation would be sought by a large number of practitioners unless it were made compulsory. The reputation of the profession would suffer from this. The fact that hospital appointments could now only be held by holders of particular qualifications might not always remain.

Dr. PYLE seconded the motion, which was lost.

Notices of amendments by Dr. Quain were next withdrawn.

Dr. Aquilla Smith withdrew a motion standing in his name.

Prof. TURNER, for Dr. Pitman, asked for instructions from the President as to what was likely to happen to the existing Council pending the first assembly of a new Council under the Medical Bill when it became law?

The PRESIDENT said he had thought of this subject. In 1858 the Council was charged with, and undertook, certain duties. He saw no reason for changing the common principles of procedure on the part of the Council so long as it continued to exist. It was for the Council, if it thought fit, to direct its President in this matter. It was the duty of the President to act for the Council. It was very uncertain if the Bill would go through during the present session, but if it was possible, it would. The duties of the Council must be discharged till the new Council came into being, the date of which, in the Bill, was March, 1884.

Mr. TURNER asked if a meeting of Council would be necessary to transfer its obligations to a new Council?

The PRESIDENT could not at once answer this. He took the opportunity of speaking in highly appreciative terms of the work done by the Registrar, and of the admirable manner in which the Council's printers had done their work.

Dr. LYONS informed the Council how its duties and obligations might be transferred without difficulty by inserting an appropriate clause in the Bill.

Mr. TURNER proposed, and Mr. SIMON seconded, a vote of thanks to the President, Mr. SIMON making an eloquent and feeling speech in fulfilling the duty falling to him.

Dr. ACLAND responded briefly, and formal votes then closed the Session.

WEDNESDAY, MAY 2, 1883.

THE MEDICAL BILL.

THE Committee stage of the Bill was taken on Thursday week, and the measure was reported and received some further amendments on Thursday last in the House of Lords, and the Committee stage passed off without any episode of serious import to the future of the Bill. The questions to be contested were—*a.* The affiliation of the State licentiate to a licensing body as one of its diplomates; *b.* Uniformity of educational and examination systems throughout the Kingdom; *c.* The right of University students to special exemptions and privileges; *d.* The allocation of the funds arising from the examination fees.

The Government refused to require the central board examinee to take a diploma as an essential of registration, but it amended the Bill in such a way as to make the affiliation, if not indispensable to the student, at least much to be desired by him. As the Bill had previously stood, the central board examinee would acquire the title of L.M.S.M., or licentiate in medicine, surgery, and midwifery, which title would appear attached to his name in the Register, and would be available for all titular purposes. Presumably many persons, having received this title, would not care to go

further to obtain an additional or higher diploma; but as the Bill has been now amended, the central board examinee is not endowed with any title or alphabetical distinction, although he is admissible to the Register and entitled to all the privileges of a registered practitioner. He will appear in the official list with a blank after his name, and it is reasonably assumed that, in nine cases out of ten, he will covet some distinguishing mark of academic culture, and will, accordingly, seek a diploma or degree.

It is to be understood that the primary examinations will continue to be held by the licensing bodies, the final or practical test being the "Staats examen" held by the central board. Therefore it may be presumed that the student who has passed the primary tests at a college will go back thither after the final examination and take its diploma, and, it is to be hoped, go forward in after-life to the fellowships, doctorates, and other higher degrees which are to serve as his professional decorations. It seems to us that this anticipation is reasonable, and that the Bill, as it now stands, will serve the purpose desired by those who advocate compulsory affiliation.

The uniformity of standard of final examination throughout the Kingdom has been provided for by a new clause in the Bill, which declares that the scope of the examinations shall be identical, and that similar values shall be assigned to the same subject before each divisional board. There is, however, no provision for uniformity of curriculum or fee, and Lord Carlingford is of opinion that these points may be left to adjustment by the Medical Council. With great respect, we dissent from the Lord President's view, for we object to these vital elements in the success of the new system being left to the chance of a scramble in the Medical Council. Should the clause pass in this form the curriculum and fee of the future will be the minimum tolerated by the Council, because, without doubt, any divisional board which desires to keep a high standard of education and price will be forced by competition to come down to the level taken up by the lowest of these boards, presumably that of Scotland. We regret this decision of the Government, and trust that an effort will yet be made to reverse it.

A new clause was moved by Lord Balfour of Burleigh, in the interest of the Scotch Universities, providing that a graduate, or he who presented a certificate of primary examination at a University, should be admitted to the divisional board examination on payment of the bare cost of examination. This is a proposition which, in the case of mere matriculant students, ought not to be tolerated for a moment, and it was to be expected that the licensing corporations would join in a shoulder-to-shoulder opposition to it. A University which requires its medical licentiates to fulfil a complete course of academic training, and to give evidence of culture by possession of a full degree in Arts, is entitled to respect and to special consideration in the settlement of medico-educational affairs, and there would be, therefore, nothing inequitable in permitting its graduates, in consideration of the serious expense which they had already incurred, to obtain the final *imprimatur* on nominal terms. But the *soi-disant* University which gives its medical degrees and doctorates without academic study or special culture is entitled to no such privilege, and we can hardly under-

stand the ground upon which such advantages can be claimed. Universities such as these—for example, the late Queen's and the present Royal Irish—are in no respect more deserving of consideration than any licensing corporation. Their sole Arts requirement is little if anything higher than that of any of the qualifying bodies, and they seem to us to forfeit much of their claim to recognition as educational bodies by engaging openly in a trade in M.D.'s, and using their academic quality to cover the sale of diplomas under the title of the Doctorate. We repudiate emphatically any right in the student of such a University to assume a higher position or claim any greater privilege than the student of any of the licensing bodies, and we can conceive no reason why a candidate should obtain a drawback of one shilling in his fees simply because he has paid a five-shilling matriculation and passed a shabby entrance examination in an institution which grants higher degrees to other and more cultivated persons. The Lord President has proposed to meet this objection by the use of the word "Undergraduate," by which he no doubt meant to indicate a student who has gone forward in Arts concurrently with Medicine, and is a *bona fide* member of the University when he presents himself for his final examination.

The allocation of the surplus funds arising from examination fees is left by the Bill in a state of uncertainty. A change has been made in the Bill by which the disposition of this surplus is transferred from the Medical Council to the divisional board; but the balance remaining from registration fees remains with the Council. But as no one knows what the State examination fee is to be, no one can form the least judgment whether there will be any surplus to divide; and, as for the Council fund, the wording of the clause under which it is to be distributed is so vague that it might be voted to almost any conceivable object.

We have pointed out these faults in the Bill in no hostile spirit, but simply because we are most anxious that a measure which gives so much promise of benefit to the public and the profession should not pass in a lame and impotent form.

THE TENURE OF OFFICE OF POOR-LAW MEDICAL OFFICERS.

WE have repeatedly urged the opinion, derived from careful examination of the Acts of Parliament governing the matter, that neither the Local Government Board nor any one else has power to dismiss a medical officer as long as the duties of the office are efficiently performed.

In the case of Dr. Kenny, who was dismissed by the Irish Local Government Board for political reasons, we insisted that such dismissal was *ultra vires*, because the Local Government Board, though empowered to remove an officer whom they "deem unfit" for the discharge of his duties, had, in our opinion, no power to take cognisance of any unfitness save that which is directly related to the duties of the office in question.

Dr. Kenny resisted the action of the Local Government Board before the law courts; but before the case came to a decision, the Board caved in and reinstated him.

The same question is now in dispute in the case of Dr. Whitmarsh, whose name will be familiar in connection with the Hounslow poisoning case. At a recent meeting of the Brentford Guardians a letter was read from the Local Government Board, a duplicate of which had been sent to Dr. Whitmarsh, the Poor-law Medical Officer for the Hounslow district. The Local Government Board call upon Dr. Whitmarsh to resign his office, as they "would not be justified in resisting the wishes of the Board of Guardians." A reply from Dr. Whitmarsh to the Local Government Board was also read, in which he maintained that when elected to his present post he signed a contract which he has faithfully carried out; his appointment he considers a life appointment so long as he carries out his duties satisfactorily, and this he contends he has always done; and as he would eventually have been able to retire on a pension he declines to resign. He would rather, he asserts, be dismissed than resign the office he is entitled to hold, since anything extraneous to his duties does not, or ought not, to come under the cognisance of the Local Government Board, and should they dismiss him they will be acting illegally.

The question at issue between Dr. Whitmarsh and the Board is of extreme importance to Poor-law medical officers throughout the kingdom, especially as it seems to be the deliberate policy of both the English and Irish Local Government Boards to relieve themselves of responsibility and of the trouble of contending with Boards of Guardians by throwing overboard their own officers. This policy is being worked out by the Irish Local Government Board by the promulgation of a general order which enables the Board of Guardians to dismiss its medical officer at their discretion, for unknown offences, subject only to a sanction by the Local Government Board, which we have reason to anticipate would be granted (to save the Board trouble) as a matter of course. We referred to this matter in a recent number, and we reminded our readers that the Board recently encouraged a Board of Guardians to deprive of office a workhouse surgeon who had served for thirteen years without any challenge of his efficiency, and whom the Local Government Board itself declared to have merited no such treatment; and they did this act to conciliate the caprice of influential guardians, and to save themselves the responsibility and trouble of a contest on behalf of their own officer. This may appear to be a rash accusation against a public department, but we make it with, as we believe, a full knowledge of the circumstances, and with the conviction that proceedings and motives cannot be truthfully expressed in other terms.

On the 18th of December, 1882, a new general order for the administration of unions was promulgated, which varied former orders, so as to enable the Local Government Board to shift the responsibility of dismissal on the Boards of Guardians. We have not appealed to the English and Irish Boards to act towards its officers as is manifestly right, but we demand that they shall act legally and at least consistently with their own precedents and their own rules, and we regret that the conduct of the Irish Board obliges us to say that it appears insensible to any influence, save a fear of Parliament and of the law courts, and that no redress can be expected from

it except by calling into action those powers which are competent to restrain it.

These new rules promulgated by the Board are, in fact, totally illegal and *ultra vires*. The Board has no more power to make them than to dictate orders to the Lord Chancellor, and if it acts under legal advice of any value at all, it must have been told that the Act of Parliament distinctly invalidates any or every attempt to shift the responsibility of dismissal of its officers to any person or body whatever. There is but one Act of Parliament which governs the matter; it runs thus:—

“It shall be lawful for the Commissioners as and where they shall see fit, by their order, to direct the guardians of any union . . . to appoint such paid officers as the Commissioners shall think necessary . . . and the Commissioners may and they are hereby empowered to . . . direct the mode of the appointment and determine the continuance in office or the dismissal of such officers and the amount and nature of the security, &c. . .”

It will be noted that under this section the Commissioners—and no one else—are to “determine the continuance in office or the dismissal of such officers.” These words of themselves might be considered sufficiently explicit, but they are confirmed by the phraseology of the 33rd section, and by the Order originally made by the Commissioners themselves, and now, with singular inconsistency, reiterated. The 33rd section says:—

“The Commissioners may and they are hereby authorised and empowered as and when they shall think proper by their order, either upon or without any suggestion or complaint on that behalf from the guardians of any union to remove any paid officer appointed under the provisions of this Act whom they shall deem unfit for or incompetent to discharge the duties of any such office.”

It is here set down—one would think—sufficiently clearly that the Commissioners are the persons to dismiss and that the guardians have no power in the matter save to offer “suggestion or complaint” which the Commissioners may or may not give effect to; and it is to be noted that the officer is liable to dismissal only upon incompetency or unfitness, or for refusal to obey the orders of the Commissioners—it being clearly the intent of Parliament that the officer should not be open to removal because of declining to fulfil the guardians’ orders, or to conform to their personal caprice, and that he should be to that extent independent of them in the discharge of his duties.

Neither in this clause, nor in any other part of any Act of Parliament that we can find, is there any power whatever given to the Board to delegate dismissal powers to any person or body; and, indeed, such delegation is contrary to the whole spirit of Irish Poor-law legislation: The Commissioners themselves interpreted the law in this sense, for, acting upon the authority of the law which we have quoted, they made the following rule:—

ARTICLE 39.—Every officer . . . holding any office under this Order shall . . . continue to hold the same until he die, or resign, or be removed by the Local Government Board, and every porter or assistant may be dismissed by the Board of Guardians without the consent of the Local Government Board.

It will be noted that herein a marked distinction is drawn between those menial servants which the guardians might dismiss, and those higher officers which the Local Government Board alone was entitled to deal with; and

nothing can be clearer than that that Board, and they alone, have power to remove the higher officers. This rule has been transferred unchanged from the old rules to the new, and its presence in the Order of December 18th, 1882, serves to illustrate the slovenly way in which such documents are drawn up in the offices of the department, and how little confidence may be placed in the legal advice under which the Board acts. Here we find the Board stating that “every officer shall continue to hold office until he die, or resign, or be removed by the Local Government Board,” while the very next rule (which we have already quoted) says that the same officer may be dismissed by a third party.

The Irish Medical Association has taken the highest legal advice on the point, and has received the following replies to its queries:—

1. “I am of opinion that the Local Government Board have no power to delegate to Boards of Guardians any authority to dismiss or suspend the medical officer of the union, and that the general orders to this effect in the Articles 39 and 40 of their recent Circular are *ultra vires* and illegal.”

2. “I find no provision in any of the Acts in relation to the power of suspension. In my opinion, neither the Local Government Board nor a board of guardians have power to suspend a union medical officer, or to deprive him of his salary, except from the date of his dismissal by the Local Government Board, and that the provision in Article 36 of the recent Circular as to the deprivation of the medical officer’s salary from the date of suspension is also *ultra vires*.”

The Irish Local Government Board has been referred to the sections of the Act of Parliament, as above quoted, and it seeks refuge in the third section of the same Act, which says that—

“The Commissioners are authorised . . . to make and issue orders for the government of workhouses . . . and the poor therein, and for the guidance and control, appointment and removal of the officers thereof, and for guidance and control, according to the intentions of this Act, of all guardians, wardens, and other officers, paid or unpaid, acting on the management or relief of the destitute poor.”

The Board expresses the opinion that this section gives them power to “authorise boards of guardians to dismiss certain officers described in the general order,” in which view not only we, but much higher legal authority entirely disagree. The Board may, under this clause, make any rules it pleases, “according to the intentions of the Act;” but it has no power to make any decree which goes in the smallest tittle against or beyond the words of the law. The plea thus urged by the Local Government Board is puerile, and we believe it would not stand five minutes before a court of law, and we hope that the Board will see the wisdom of taking better legal advice than that on which it has acted, and—if advised that its rules are *ultra vires*—rescinding them with as good grace as possible. If the Board does not adopt this course, it may reasonably assume that the first case of dismissal by a board of guardians will involve both the guardians and the Commissioners in a lawsuit and a judicial decision which will not profit the guardians or do credit to the legal acumen of the law adviser of the said Board.

Notes on Current Topics.

Prostitution and its Regulation.

At the present moment, when more than usual consideration is being given to the question, how to deal with the so-called "social evil," an article on "Prostitution in Paris" which appears in the new number of the *Westminster Review*, deserves to receive, as it will undoubtedly command, a more than passing attention. The essay is in itself an appreciative and critical study of the important services rendered by M. Yves Guyot on the cause of remedying the abuses created by the institution of the French *Police des Mœurs*, and it details with striking force the serious evils which have followed in the wake of the system which now stands finally condemned. At the time when this article underwent revision, Mr. Stanfeld's motion disapproving of compulsory examination of women under the Contagious Diseases Act, was still to be accepted by the House of Commons, but in the success achieved by that motion the *Westminster's* contributor must necessarily find an agreeable indication of the sympathy with which his exordium against the Act will be received by all those who have persistently agitated for a repeal of the statute. We cannot, of course, pretend to rebut any part of the evidence so laboriously accumulated and so eloquently expounded by M. Guyot in respect to the Parisian *Police des Mœurs*; but it need hardly be insisted on that outrages such as those he complains of would never have been tolerated in a country like England. By and bye it will be incumbent on our legislators to discover and ordain some *régime* in place of the abandoned compulsory clause of the existing Act, as a means of opposing the ravages of specific disease among the classes of society dealt with under this law. It would be alike impolitic and unscientific to make no efforts in this direction; and in trusting, as future trust must be put, in the voluntary submission of affected individuals, it will be found, possibly, that less advantage than has already been obtained will be forthcoming. The vital consideration, therefore, will be to so arrange that inducements to both sexes to undergo treatment and cure shall be held out; and with this object the principal suggestion in the article referred to, that of abolishing special hospitals as an asylum for infected persons, will have to be particularly considered. The stigma attaching to treatment in such institutions cannot be talked away, and probably the method of meeting the difficulty may be to encourage men and women who are suffering from specific diseases to undergo treatment in general hospitals. But the whole subject is a complicated one, and there is much to be said on either side.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Bradford 16; Birkenhead, Derby 17; Sheffield 18; Brighton, Bristol 19; Edinburgh, Preston, Plymouth, Salford, Leicester, Birmingham, Leeds 20; Sunderland, Cardiff 22; London, Nottingham, Bolton 23; Huddersfield 24; Newcastle-on-Tyne, Portsmouth, Liverpool, Halifax 25; Hull 26; Oldham 27; Manchester 28; Wolverhampton 29; Norwich, Blackburn 30; Glasgow 32; Dublin 37.

Dr. Benjamin Wills Richardson, of Dublin.

WE deeply regret to announce the death, on Saturday night last, from cardiac disease, of this much-esteemed gentleman, who held the position of Chairman of the Surgical Court of Examiners of the Irish College of Surgeons, and Senior Surgeon of the Adelaide Hospital. Dr. Richardson was a physiologist and histologist of the highest repute, and having held the office of Secretary of the Surgical Society of Ireland for very many years, was as popular as he was respected. We hope to be able to do fuller justice to his memory in our next issue.

The British Medical Association and the Medical Bill.

THE paralytic attitude of the Medical Reform Committee of the British Medical Association takes us by surprise, and suggests that "reform" is needed somewhere else besides amongst licensing bodies, schools, and medical practitioners. The Bill which is to revolutionise medical affairs, make or mar education, and either kill or reanimate the quack, has passed five stages in the House of Lords, and yet we see no sign of the existence of the Medical Reform Committee, save a number of petitions sent in before the second reading of the Bill to support its principle. Since then the Committee would seem to have retired from business, for it has left the future of medical education, the influence of the profession thereon, the recognition of practitioners abroad, and the control of quackery at home, to be settled amidst the internecine squabbles of licensing bodies, or to settle themselves in any way that the Bill drawer thinks best. In our opinion the British Medical Association should have occupied an aggressive rôle in all the questions in dispute—acting on behalf of the public and the profession as contra-distinguished from the licensing bodies; but, even if the Association did not consider the settlement of educational affairs within its function, it is clearly its duty to look after the interests of the general practitioner. It has agitated perseveringly and effectually in order to secure to the practitioner a voice in the administration of medical affairs; and, having gained the cause and created the "direct representative," it has without protest allowed that functionary to be reduced to nonentity by the terms of the Bill. The four members of the reformed Medical Council whom the profession will select are to have the titular honours of the office and the distinction of coming to London for a few days in each summer to register the decrees as to medico-educational matters which have been made by the medical boards within the rest of the year; but they are to have no place on those boards, nor any right to take part in the arrangements for education and examination in their own country. We contend that a direct representative who is limited to these occasional supervisory functions is no representative of the medical profession in any true sense; and that, in allowing him to be excluded from the real executive work of medical education and examination, the British Medical Association is forgetful of the trust which the medical practitioners of Great Britain have reposed in it, and of the issues for which it has so long contended. We profess ourselves as ardent in the cause of reform, and as anxious to pass a good bill as any member of the Medical Reform Com-

mittee; but we are not satisfied, as the Committee seems disposed to be, to "open our mouth and see what the king will send us." We hope, by remonstrance and representations to the Legislature, to make the Bill much better than it originally was; and we regret to find that the Association has no suggestion to make in this direction, and seems content to look on while others work out the needful reforms. If the British Medical Association is willing that the direct representative should be a medical lay-figure, we are not; and we hope to find other professional organisations less lethargic than the Medical Reform Committee.

The Royal Society.

AMONG the fifteen candidates for election to the Fellowship of the Royal Society of London who have been nominated by the Committee of Selection for the present year, there occur the names of four members of the medical profession—viz., Surgeon-Major James Edward Tierney Aitchison, M.D.; James Crichton Browne, M.D., LL.D.; Surgeon-Major George Edward Dobson, M.B.; and James Matthews Duncan, M.D. The last-named physician was last week chosen by the Queen in Council to act as Crown representative on the General Medical Council for a period of five years, in succession to Sir William W. Gull, Bart., resigned.

The Medical Union Society.

ON Saturday next, May 5th, the Medical Union Society will discuss the new Medical Bill, the debate on which will be opened by Dr. J. G. Glover. In view of the increased attendance of members and visitors likely to be attracted, the meeting will take place in the great room of the Society of Arts, which has been secured for the occasion. The chair will be taken at 8 o'clock by Mr. Henry Power, F.R.C.S.; and visitors' cards may be obtained on application to the Honorary General Secretary, Mr. Charles H. Wade, or to the Hon. Sec. for Debates, Mr. H. J. Read, Medical Union Society, 10 Adelphi Terrace, London, W.C.

Fashionable Malthusianism.

THE tendency among American women to limit the natural increase of mankind is seriously moving the more reflecting of their compatriots to expostulate against the wholesale use that is being made of "instruments of prevention." The *Cincinnati Lancet and Clinic*, March 31, contains an article on the subject from the pen of Dr. Wm. A. Rothacker, who has apparently enjoyed exceptional opportunities of judging the extent to which the practice extends on the other side of the Atlantic. The reason for the paper is to be found, according to an editorial comment in the same number of the journal in which it appears, in the attitude assumed towards the question by a local secular print, the conductors of which are unable to see other than praiseworthy conduct in the acts of women who protect themselves by artificial means from the troubles and cares of child-bearing. Dr. Rothacker enumerates a whole armoury of aids in the shape of syringes, pessaries, cups, and other mechanical contrivances for destroying or hindering the access of spermatozoa to the uterus. He does not, however, discuss

the question from the purely medical standpoint; but it is sincerely to be hoped that no practitioner will for a moment hesitate to acquiesce in the assurance that incalculable injury is done to the female organism by constant arrest of natural functions, and that all such adventitious provocatives of sterility carry in their train the dangers of unlimited disease. What is American custom to-day may be British fashion next week.

Parkes Museum.

THE new building which is to be the future permanent home of the Parkes Museum of Hygiene, situated at 74A Margaret Street, Regent Street, W., is to be formally opened to public use on Saturday, May 26th, by H.R.H. Prince Leopold, Duke of Albany, who is President of the Museum. An important feature of the new premises is a commodious reading room, which has been specially arranged with a view to encourage students to make use of the facilities afforded by the Museum for instruction in practical hygiene. This object will be further assisted by lectures and demonstrations, which are to be given at intervals in the future; and there is altogether every reason to anticipate that the Parkes Museum will become a most important educational centre for all that relates to sanitary and hygienic science.

Prevention of *Blenorrhœa Neonatorum*.

A RECENT official circular from the magistracy of Vienna to the medical men of that city draws attention to the experiments and observations made in Professor Spaeth's clinic by Dr. L. Koenigstein on the best method of preventing the ophthalmic *blenorrhœa* of infants. It affirms that the disease is most frequently caused by infection from the genital passage of gonorrhœic mothers; but that it may also arise later, by contagion, from one eye to the other, or from one child to another in cases in which sufficient care has not been taken by the midwife or nurse to prevent it. Credé's method of prevention has shown itself after prolonged trial thoroughly reliable. This method is as follows: Immediately after separating the child from its mother it is bathed, and during the bathing the eyelids and their immediate surroundings are carefully cleaned by folds of linen dipped in lukewarm water; afterwards the eyelids are gently separated, and into each eye a drop of a two per cent. solution of nitrate of silver is inserted. The circular further states that midwives are not expected to carry out this prophylactic measure themselves except under close supervision, but medical men are requested to make known its advantages, not only to the midwives of their circle, but also to the mothers, and they are also requested to notify to the authorities all cases of such *blenorrhœa* in which the attending midwife has neglected to immediately call in the assistance of a physician. Such action as this on the part of medical authorities cannot fail to have good results.

SURGEON WILKINSON, of Limerick, whose death at the advanced age of ninety we recently recorded, has bequeathed £1,000 to the Royal Medical Benevolent Fund Society of Ireland.

The Need of a Midwives' Registration Bill.

IN connection with the case of a Sheffield midwife who was recently condemned to twelve months' hard labour for infecting a patient with syphilis, and which was referred to by us at the time, the following petition in favour of speedy legislation as regards a Midwives' Registration Bill has been presented to Parliament by the North-Western Association of Medical Officers of Health. The petition is signed on behalf of the Association by J. Makinson Fox, President, and Francis Vacher, Secretary :

"To the Right Honourable the Commons of Great Britain and Ireland in Parliament assembled. The Petition of the North-Western Association of Medical Officers of Health, humbly sheweth,—

"That your petitioners are a body of medical officers of health in the counties of Lancaster, Chester, and Derby, and in the West Riding of the county of York, and of others interested in the preservation of public health. That, in view of the facts disclosed in the course of a recent trial of a midwife at Sheffield for inflicting grievous bodily harm, your petitioners are impressed with the urgent necessity of some State regulation for the control of all persons practising midwifery for gain. Your petitioners therefore humbly pray that your Honourable House will, at an early date, take this subject into consideration, and pass a Bill requiring the due instruction and examination by competent experts of all persons desiring to practise midwifery for gain, the registration of such persons as may be found qualified, and their supervision and control by a registering board, who shall have power to suspend or remove from the Register any midwife in case of misconduct. And your petitioners will ever pray, &c."

Elections at the Irish College of Surgeons.

THE annual election of the various Courts of Examiners of the College took place yesterday (Tuesday) at too late an hour to allow of our announcing the result to-day. Owing to the much-lamented death of Dr. Richardson, the Chairman of the Surgical Court, a death vacancy existed. All the outgoing Examiners offered themselves for re-election, and in addition to them the following claimants sought election:—Mr. A. H. Benson, of St. Mark's Ophthalmic Hospital; Mr. Croly, of the City of Dublin Hospital; Mr. Kendal Franks, of the Adelaide Hospital; Dr. Fitzgibbon, of the City of Dublin Hospital; Dr. Gogarty; Dr. Hayes, Stevens' Hospital; Dr. Kilgariff, of the Mater Misericordiae Hospital; Mr. Ormsby, of the Meath Hospital; and Dr. C. H. Robinson.

By the charter of the College, the election is conducted by seven councillors chosen by lot, and professors and lecturers are ineligible—restrictions which ought to be removed if the Council sees it possible to do so. For the Midwifery Court there is no contest; but for the Preliminary Education Court, Dr. Morton, of Nenagh, who formally held a seat on it, seeks to be elected.

A meeting of the Fellows will be held next Saturday, the 5th of May, at one o'clock, to elect a member of Council in room of Mr. Croly, who has resigned in order to present himself for the Examinership.

The candidates for the vacant seat on Council are Mr. Baker, who acted on the executive of the College last year, and Dr. William Stoker, of the Ledwich School.

THE Worshipful Company of Goldsmiths has voted a donation of £5,000 to the London Hospital.

The Night-Lecture Sham Certificate System in Dublin.

ON Tuesday and Wednesday last an animated discussion took place upon a letter which Dr. Jacob, of Dublin, had addressed to the General Medical Council, in which he exposed the prevalent issue of fictitious certificates of attendance by one or more schools and hospitals in Dublin, and the existence of a system of night-lecturing as a cover for this practice.

It was moved by Mr. Simon, and seconded by Dr. Quain: "That for the purposes of the Council's Recommendation 21, and of regulations by which the licensing authorities may desire to give effect to it, the 'four years' required to be spent in professional study must be four years during which professional study shall have been adequately followed by the candidate, as his true industry and the main occupation of his time; and that, in the opinion of this Council, much caution ought to be used in admitting as part of the four years' curriculum any considerable time during which a candidate had given most of his industry to other pursuits, as, for instance, if he had been regularly engaged for the greater part of each day in the duties of some non-medical calling followed by him for his livelihood."

An amendment was moved by Dr. Matthews Duncan, and seconded by Mr. Turner:—"That the Council having had its attention drawn, by the letter of Dr. Jacob, to the use of fictitious certificates, object in the strongest manner to their issue by teachers, and their use by candidates for licence. They recommend that no certificates be granted to a student who has been absent from more than one-fourth of the lectures required in any course, and direct that this be added to the Council's 'Recommendations on Education and Examination.'"

By permission of the Council, both motion and amendment were withdrawn, and it was agreed "That Dr. Jacob's letter be referred to the Irish Branch Council for such inquiry as they may find needful, and for report thereon."

To the inquiry which the Council desires to institute, no one, least of all Dr. Jacob, can have the least objection. The more questions are asked and the more light is let in on the existing system, the more clearly will these educational frauds be exposed, but the inquiries must be made with a more earnest intent than when the subject was before remitted to the Branch Council, and the information elicited must be acted upon with a more evident disposition to eradicate the corrupt practices. It is hardly creditable to the Irish Branch Council that the exposure of these abuses should have come from a private individual, still less creditable that the General Council has been obliged to ask them a second time to honestly investigate and take action, and it will be least of all creditable if the Branch Council hesitates to expose fearlessly this disgraceful traffic.

DR. LYONS, M.P., has received an offer of 50,000 trees from an extensive French firm in the Department of Loire-et-Cher for planting in Ireland.

A Richly-merited Distinction.

HER MAJESTY has instituted a new Order for women who have done good service in civil or military hospitals while nursing the sick and injured, and henceforth the Royal Red Cross, as the distinction is to be called, will be a prize most richly merited by those whose tenderness, assiduity, and sacrifice in time of war and epidemics entitle them to high honour and reward.

Proposed Hospital for North London.

THE scheme mooted some time ago to provide a general hospital for the North London district formed the subject of discussion at a meeting specially convened to consider it on Saturday afternoon last, at the Athenæum, Highbury New Park. In the absence of the Duke of Westminster, the chair was taken by Lord George Hamilton, who was supported by numerous well-known philanthropic ladies and gentlemen. The object of the meeting was not secured without some rather unpleasant interruption of its harmony, for an amendment hostile to the resolution declaring a new hospital to be necessary received considerable support from those present. The Duke of Westminster's letter of apology for non-attendance, too, was distinctly antagonistic to the movement, which he declared had lost its *raison d'être*, since it had been resolved to enlarge the existing Great Northern Hospital. Eventually resolutions approving the scheme, and that a building fund should be raised, were passed, and the movement will possibly advance now another step. The interest of leading medical men in the district, however, seems not to have been enlisted on its behalf.

The Anti-Vaccination Controversy.

BEFORE the next number of this journal is in type our readers will have learned the fate of the present Vaccination Acts, as the subject will be brought before the House of Commons to-night by Mr. Hopgood. Judged in the light of past experience, but little time should suffice to defeat the intention of the mover of the following resolution:—

"That, in the opinion of this House, it is inexpedient and unjust to enforce vaccination, under penalties, upon those who regard it as unadvisable and dangerous."

To this Dr. Cameron will move as an amendment:—

"That, while it is inexpedient to abolish compulsory vaccination, our vaccination laws might with advantage be amended in points of detail."

It is understood that the Government will maintain an observant attitude during the discussion, which probably means that the way of the wind will determine their action; and, after the unexpected success of the Anti-Contagious Diseases Acts party last week, a retrogressive policy may also be in store for vaccination.

The New Association of Fellows of the Royal College of Surgeons of England.

THE conditions hitherto regulating the privileges possessed by Fellows of the Royal College of Surgeons of England have been so generally regarded as unsatisfactory that, as our readers are aware, an Association of Fellows has been formed, with the object of obtaining amendments long deemed desirable. In another part of our present issue the programme of the Association will be found.

Prolonged Intestinal Obstruction.

DR. HEUSTER, of Mobile, reports a remarkable and interesting case of intestinal obstruction of twenty-one days' standing, which was ultimately relieved by injections of carbonic acid gas. The patient was a woman, who had been confined after a tedious labour, accompanied by extensive perineal laceration, and followed by an attack of puerperal fever of three weeks' duration, and subsequently severe colic. The attack developed into a well-marked case of ileus. All the usual remedies—calomel and opium, warm poultices, injections of soap and water, or ox gall and water, morphia, extract of belladonna, &c., &c.—failed to give relief. The stercoraceous vomiting steadily continued. On the seventeenth day it was determined to make an exploratory incision into the abdomen, but owing to difficulty in procuring assistance the operation was postponed to the next day. Dr. Heuster then obtained a large siphon of seltzer water, attached an india-rubber tube, which he passed about eighteen inches up the bowel, and then turned on the gas. Before the bottle was half empty the fæces began to flow out, and when the flow stopped the gas was turned on again, to be interrupted by more fæces; and so it was kept up until the bottle was empty, and the bowels too, apparently, from the quantity passed. After that the patient's stools became regular, and she had no further trouble with them. Dr. Heuster remarks that, as the exact seat of the obstruction could not be ascertained, its cause remained doubtful; but he inclines to the opinion that the elastic and pervading force of carbonic acid gas thrown far up into the colon readily overcame the obstruction, and would appear to be the readiest means of treatment in similar cases.

IT is the intention of the Princess of Wales to accompany His Royal Highness on the occasion of his proposed visit to Eastbourne in June next to open the Princess Alice Hospital there.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 31, Madras 38, Paris 31, Geneva 21, Brussels 32, Amsterdam 31, Rotterdam 31, The Hague 26, Copenhagen 28, Stockholm 29, Christiania 22, St. Petersburg 41, Berlin 26, Hamburg 31, Dresden 24, Breslau 35, Munich 36, Vienna 36, Prague 43, Buda-Pesth 35, Trieste 29, Rome 34, Turin 33, Venice 29, Lisbon 33, New York 29, Brooklyn 21, Philadelphia 24, Baltimore 23.

THE highest annual death-rates from diseases of the zymotic class in the large towns last week per 1,000 of the population, were—From whooping-cough, 1·8 in Derby, Manchester, and Hull; from measles, 1·2 in Manchester; from scarlet fever, 1·5 in Hull, and 1·8 in Birkenhead; and from "fever," 1·2 in Portsmouth, and 1·4 in Plymouth. The 40 deaths from diphtheria included 19 in London, 9 in Glasgow, 2 in Edinburgh, 2 in Portsmouth, 2 in Birmingham, and 2 in Preston. Small-pox caused 2 deaths in London, 2 in Wolverhampton, one in Leeds, and one in Newcastle-upon-Tyne.

We are informed that Mr. J. Netten Radcliffe has sent in his resignation as assistant medical adviser to the Local Government Board in consequence of ill-health.

We are requested to announce that the annual oration and *conversazione* of the Medical Society of London which under ordinary circumstances should take place on Monday next, is postponed for a few weeks to allow of the completion of the Society's new meeting-room and other premises for the occasion. The date will be announced as early as possible.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE SCOTCH CORPORATIONS AND THE MEDICAL BILL.—The remarks of Lord Balfour of Burleigh on the demand of the corporations for another representative on the future medical board are not reassuring to those bodies. Lord Balfour pointed out the great distinction between the Universities and the corporations, the former doing good work both as teaching and examining bodies; the latter are only examining bodies doing even this but indifferently well. In fact, it may be almost confidently asserted that but for the corporations there had been no need for all this outcry for legislation. For years these corporations have been accumulating wealth, not one penny of which has been spent in the education of the candidates from whom so much money has been drawn. The College of Surgeons is even the landlord of the premises occupied by some of the lecturers of the medical school, on the reputation of which, and the mildness of the examinations, they have so long traded. The Universities have reason to feel sore, for it is not they, but the corporations, which have given rise to the remark so often heard in England, "Oh, anybody can pass in Scotland." The oft-repeated boast of some of the old Fellows of the College of Surgeons that they are only an examining body will soon cease to be heard, and the advice given some years ago by one of the Fellows to become a teaching body will now be keenly felt in all its wisdom.

The Extra-Mural School.—Since the introduction of the Medical and the Universities Bills, the mania for petitioning has spread far and wide, and genuflexions are becoming chronic. From the extinction of the corporations the Extra-Mural School has nothing to lose or fear, but it is otherwise with the growing power of the Universities. Care should be taken, therefore, to protect the interest of the extra-mural lecturers, and for this purpose, we believe, steps have been taken in the proper direction. The destruction of the Edinburgh Extra-Mural School would be the ruin of Edinburgh as a medical school. It is fortunate that no such result is probable.

The Edinburgh Royal College of Physicians and Extra-Mural School of Medicine.—Petitions to Parliament have been prepared by the Royal College of Physicians and the Extra-Mural School of Medicine, Edinburgh, with reference to the new Medical Bill. The College of Physicians say that, while approving generally of the principle and of many of the provisions of the Bill, they are of opinion that if it passed in its present form it would not only affect most injuriously the interest of this College and the other medical corporations of Scotland, but that its enactments would seriously interfere with the progress of medical education. They also say that, if the Bill comes into operation in its present form,

they anticipate that in course of time the Extra-Mural School of Edinburgh will completely disappear; and that, should this occur, a great blow would be struck at the whole Medical School of Edinburgh, from which in no long time the University itself would suffer. The lecturers in the Extra-Mural School of Medicine, in their petition, make statements of like import; and to remedy the injustice which they thus anticipate, they suggest that no teacher should examine his own students, that the proportion of University members on the Medical Board for Scotland be reduced by increasing the representation of other bodies, and that the University representatives be chosen by the General Councils of the different Universities, which consist of the general body of graduates, and not by the Senatus or other University authority.

GLASGOW CITY DEATH-RATE.—For the week ending with Saturday, the 21st ult., the death-rate of Glasgow was 34 per 1,000, as compared with 33 in the preceding week, and 27, 27, and 29 respectively for the corresponding periods of 1882, 1881, and 1880.

EDINBURGH HEALTH STATISTICS.—There were 86 deaths in Edinburgh for the week ending with Saturday, the 21st ult., and the death-rate was 19 per 1,000. There were 15 deaths under 1 year, and 25 above 60 years. Diseases of the chest accounted for 32 deaths, and zymotic causes for 3, of which 1 was due to measles, while the intimations of that disease numbered 22.

THE EDINBURGH MERCHANT COMPANY AND THE UNIVERSITY.—At a stated general meeting of the Company of Merchants of the City of Edinburgh, held on the 24th April, it was recommended by the master, treasurer, and assistants that an additional sum of 200 guineas be voted from the funds of the Company to the University Buildings Extension Fund. The master said the reason why they made this recommendation was that they considered the University to be one of the great features of Edinburgh.

GLASGOW UNIVERSITY.—HONORARY DEGREES.—At the graduation ceremony at the University of Glasgow, on Friday, the 27th ult., the degree of LL.D. was conferred on Daniel H. Tuke, M.D., F.R.C.P.Lond.; Wm. Turner, M.B., F.R.S., Professor of Anatomy in the University of Edinburgh; and George Fleming, F.R.C.V.S., President of the Royal College of Veterinary Surgeons of England.

LORD RECTORSHIP OF THE UNIVERSITY OF EDINBURGH.—It is officially announced that Sir Stafford Northcote has agreed to be nominated by the Conservative students of the University of Edinburgh for the office of Lord Rector.

ABERDEEN UNIVERSITY.—GRADUATION CEREMONIAL.—Last week the ceremony of "capping" the graduates in medicine took place, under the presidency of Professor Pirrie. The following were the recipients:—*Degree of M.D.*—John Barrett, M.B., C.M., P. and O. Service; Harry Arthur Benham, M.B., C.M., Dundee Royal Asylum; Alexander Hill Griffith, M.B., C.M., Manchester; Frederick Mortimer Hawkins, M.B., C.M., London; William Reid, M.B., C.M., Kensington; Charles Boards Richardson, M.B., C.M., Brighton; William Dyne Steel, M.B., C.M., Abergavenny; David Tulloch, M.B., C.M., Winnipeg, Canada. *Degrees of M.B. and C.M.*—John Baker, Aberdeen; Robert Milne Beaton, Aberdeen; Alfred Brown, M.A., Welshpool; George Buchan, Aberdeen; Sylvester John Cole, Freetown, Sierra Leone; Henri Cook, Greenock; Alexander Cowley, Dublin; George Forsyth Ashley Da Costa, Kingstown, Jamaica; Francis Falconer, M.A., Aberdeen; James Thomson Fraser, Longsight, Manchester; John Gerard, M.A., Aberdeen; John Gordon, Aberdeen; Andrew Hosié, Aberdeen; John Inglis, M.A., Aberdeen; David Ireland, Brechin; Charles Jeffrey, Tarland; George Johnston, Fintray; Thomas Mair Johnstone, Ellon; John Bamford Kerr, Crawshawbooth, Manchester; James Francis Macdonald, Aberfeldy; John Matheson, M.A., Plockton, Ross-shire; Frederic Maude,

Highgate, London; John M'Combie, Oxton, Morayshire; Grenville Edwin Moffett, Calcutta; James Moir, St. Kilda, Victoria; John Draw Moir, St. Kilda, Victoria; James Murray, Nairn; Alex. Nicoll, Rhyndie; David Petty, Montrose; James Robert Purdy, Morpeth; Alex. Rennie, M.A., Weeter Fintray; James Taylor Robb, Keith; William Scott, Auchairn, Keith; William John Henderson Sinclair, Dunbeath, Wick; William Allan Stewart, M.A., Buxburn, New-hills; James Taylor, M.A., New Deer; George John Kemp Turner, Ellon; John Turner, Portsmouth; George Vincent, Bedford, Middlesex. Of the above-named candidates, John Gerard, M.A.; David Ireland, James Francis Macdonald, Alex. Rennie, M.A.; and William Scott received their degrees in medicine and surgery with honourable distinction. At the same time, William Kelty, William Ledingham Ruxton, James Lawrence Smith, and George Cardno Still were certificated as having passed all the examinations, but did not graduate.

UNIVERSITY OF EDINBURGH.—The following candidates have passed the final examination for the M.B. and C.M. degrees of this University:—Charles Aitken, M. S. P. Aganoor, M. S. Altounian, Samuel Arnold, E. H. Bannister, J. B. Batten, D. G. Bennet, Wm. Bird, Robert Blair, Frederick Bond, J. E. Bottomley, C. K. Bourne, Paul Bowes (with distinction), T. M. Bunce, P. B. Bury, J. M. Cadell, Edward Carmichael (with distinction), W. R. Carter, R. L. Clark, J. G. Cossins, R. S. Coulthard, A. S. Cumming, Richard Davidson, T. W. Dewar, W. O. Dow, H. J. Dring, T. G. Evans, H. S. Fairbank, W. C. Faulkner, J. E. A. Ferguson, William Flett, W. G. Galletly, D. J. Galloway, A. R. Gray, F. G. Greenbury, C. D. G. Hailes, P. B. Handyside, E. B. Hector, J. R. Henderson, R. S. Hubbersty, B. E. Iastrzebski, Thomas Johnstone, J. E. H. Kelsa, G. H. Kenyon, D. O. Kerr, William Laing, W. S. Lang (with distinction), T. A. Leishman, G. S. P. Loubser, W. W. R. Love, R. H. Lucy (with distinction), C. M. Macalister, W. G. M'Fee, H. J. Mackay, F. W. Mackenzie, N. J. M'Kie, W. R. M'Kinnel, Murray MacLaren, W. H. M'Lean, James M'Leod, John M'Myn, G. D. Malan, Angus Matheson, Alexander Menzies (with distinction), Duncan Menzies, Gustave Michel, David Milligan, Robert Mitchell, A. E. Morison, Daniel Mowat, W. J. Munro, Frederick Murray, J. T. Nesbit, John Noble, F. B. O'Flaherty, James Paterson, R. J. Paton, F. A. Pockley (with distinction), J. M. S. Preston, A. W. G. Price, C. A. Renny, F. G. Retief, John Rigg, John Robertson, A. H. Robinson, F. H. Simmons, William Sneddon, A. C. Stark, J. S. Stephen, H. F. D. Stephens, G. H. H. Symonds, J. C. Taylor, William Taylor, George Thomson, H. A. Thomson (with distinction), T. J. Thyno, C. G. Traill, G. A. Tullis, J. W. O. Underhill, Edmund Walker, N. H. Walker, N. P. Walker, David Wallace, T. A. Watson, S. F. Wernich (with distinction), Algernon Westlake, Claude Wilson (with distinction), J. T. Wilson, J. E. Wolphagen, A. J. Wood.

Medico-Parliamentary.

HOUSE OF LORDS.—THURSDAY, APRIL 26TH.

THE MEDICAL ACTS AMENDMENT BILL.

DISCUSSION was resumed on the clauses and amendments of this Bill; a week's interval having elapsed since it was before the House. (See Report in last number of *Medical Press*).

Lord CARLINGFORD now said he desired to submit an amendment to the House relating to

THE CONSTITUTION OF THE MEDICAL BOARDS.

When the Bill was discussed on the last occasion in Committee he threw out a suggestion which was not very well received, especially by the noble Marquis opposite. He now made another proposal to the House—that the number of representatives given by the Bill as it stood to the five Universities of England should not be altered, but that the two great medical colleges, the Royal College of Physicians and the Royal College of Surgeons, should receive an addition of two members, being one for each. He had found great difficulty in understanding the enormous and vital importance that appeared to be attached by the medical authorities of the three countries to the exact numbers which they should have a right to return to

those Medical Boards. He did not believe that the interests and views of one of the bodies would be supreme and exclusive merely because that set of authorities happened to have a majority, perhaps of one, on the Conjoint Board; nor did he believe that the interests and views of the other set of authorities would be sacrificed merely because they happened to be in a minority, perhaps of one. After having given the best consideration in his power to the whole matter, he had come to the conclusion that there was sufficient reason for increasing by two the number of representatives returned by the two principal medical corporations. Nothing could be of more importance than their influence, and that influence would not suffer under this proposal. On the other hand, it was evident that in this country the lion's share of the duty of examining and licensing candidates for the medical profession fell to those two corporations. That view had been pressed upon him in the strongest possible way by the most eminent—he might say the most illustrious—members of the profession; it was the view of the Royal Commission presided over by his noble friend; and there could be no doubt that the part played by the two great medical corporations in respect to the examination and licensing of candidates was out of all proportion greater than that by the Universities. He was glad to find that one of the Universities, which examined the largest number of candidates, was satisfied with the proposal he had made, and he hoped that that might be the case with the other Universities. It was well, he thought, that while the high educational influence of the Universities was most important and essential, and would be exercised in the fullest degree by the large number of members who would be returned to the Conjoint Board, yet that the object of the Board was not to provide the highest possible standard for examination or education, because the Conjoint Board would have nothing to do with the honours of the medical profession, but would only be concerned with maintaining a sufficient average, or rather a *minimum* standard, for all the young men who were to be admitted to the right of practice; and the two great medical corporations, with their immense experience on that subject, should have the right, he thought, of full representation on the Conjoint Board. The noble earl then moved his amendment.

The Marquis of SALISBURY complained that the noble lord had not given sufficient notice of his proposal, and said that therefore there had not been time to obtain the opinion of the important bodies concerned on the matter. He believed the Apothecaries' Society was not a body of high educational character; and as to the Victoria University, Manchester, that body had no doubt a great future before it, but could hardly set up its privileges in this matter against those of the more ancient universities.

The Earl of CAMPERDOWN was glad to hear that the noble marquis would withdraw his opposition. The Commission were certainly of opinion that it was desirable to give due representation to the Royal Colleges of Physicians and Surgeons in England, as they had taken a far more prominent part than the corresponding bodies in other divisions of the kingdom. If a victim was to be offered up, he thought it should be the Apothecaries' Society of England. He was bound in fairness to state that that society had no stronger claim to existence, in his opinion and in that of the Commission generally, than the corresponding society in Ireland which had already disappeared.

Viscount POWERSCOURT said that the Lord President had said that the two Colleges of Surgeons and Physicians in England had the lion's share of the work, but he (Lord Powerscourt) did not know that the two Colleges in Ireland had not a lion's share also. He thought it rather a misfortune that the representation of the two Colleges in England and Ireland should not be equal, or that the Government could not elect a chairman themselves who should have a casting vote.

The amendment of Lord Carlingford was then agreed to.

The Earl of GALLOWAY, in moving the amendment standing in his name, said that these four amendments were practically one, but he wished to remind their lordships that they were to the effect that the medical corporations of Scotland should have a majority of one over the Universities. It was proposed by the Bill that the Universities should have eight members of the board and the medical corporations three, and the latter bodies thought their claims were being sacrificed. His was not a proposition to increase the number of members through-

out Scotland, but to take three from the Universities and add them to the medical corporations. It had been suggested to him that the University of St. Andrews had no claim whatever to be represented, and that Aberdeen University would be quite sufficiently represented by one member.

Lord BALFOUR expressed a hope that the amendment would not be accepted, for the reason that it had been recommended by the report of the Royal Commission that the Universities of Scotland should have a preponderating representation on the board in Scotland. The Universities were teaching bodies, as well as merely examining bodies, while the medical corporations did no more than examine. Again, there had been complaints made as to the action of the examining bodies in Scotland. If there were any charge of improperly admitting students to become practitioners, it had certainly not been made against the Universities. It seemed to him that St. Andrews was regarded at present as fair game for everybody to have a hit at. He trusted the amendment would not be accepted.

Lord CARLINGFORD had nothing to add to his previous declaration on the subject. He could not admit for a moment that the Scotch medical authorities were in any way on a par as regarded the part they played in medical education and examination with the great medical corporations in England. The amendment was then negatived.

FOREIGN COUNTRIES.

On Clause 20,

Lord CARLINGFORD moved, at page 11, line 25, to add, as a separate paragraph, these words:—"Any revocation or alteration of a scheme in pursuance of this section shall not be of any validity until it has been approved by the Medical Council and confirmed by the Privy Council;" and on clause 25, page 14, line 5, to add these words:—"Her Majesty may from time to time revoke and renew any order made in pursuance of this section; and on the revocation of such order as respects any British possession or foreign country such possession or foreign country shall cease to be a possession or country to which this part of this Act applies, without prejudice, nevertheless, to the right of any persons whose names have been already entered on the Register."

The amendments were accepted.

MEDICAL TITLES.

On Clause 25,

Lord ABERDARE moved at page 14, line 19, after "use" to restore the words "and it shall be lawful for any registered medical practitioner, who has passed a final examination, as in this Act mentioned, if he thinks fit to do so, to use after his name the title of licentiate in medicine, surgery, and midwifery, or any letters indicative of such title." He thought the great medical corporations had already sufficient forms, and that those who did not desire to enter them should be allowed to use the title of licentiate.

The Earl of CAMPERDOWN and Earl CAIRNS objected, and the amendment was negatived, and the clause agreed to. Clauses 27 to 35 were also agreed to.

ADMINISTRATIVE EXPENSES.

On Clause 36,

Lord CARLINGFORD moved an amendment, the object of which was to draw a distinction between administrative expenses and those for maintaining the libraries and other property of the corporations. It also proposed that the fee to be paid by University candidates should go only to defray the charges for administrative expenses.

The amendment was agreed to.

THE ELECTION OF MEMBERS.

In Clause 51,

Lord CARLINGFORD proposed to insert, as an amendment, a proviso that, in the case of all existing medical authorities, members should be returned on the same system as they were now returned to the General Medical Council, and that, in the case of any new authority, members should be returned in the manner provided by the Privy Council.

The amendment was agreed to.

THE MEETINGS OF THE NEW BOARD.

In Clause 53 an amendment, proposed by Lord CARLINGFORD, was agreed to, postponing the date on which the first Medical Council shall come into office from the 31st of March, 1884, to the 30th of April, 1884.

PRELIMINARY EXPENSES OF THE NEW BOARD.

On Clause 55,

The Earl of CAMPERDOWN said that some provision should be made for enabling the medical board to defray necessary

expenses in the interim before a medical fund could be formed. He therefore proposed, as an amendment, to add the following provisos:—"Provided that the Medical Council shall out of such funds—that is, the funds received from the branch councils—advance to each medical board such moneys as shall be required to defray the expenses necessarily incurred before a medical fund can be formed. Provided also that the Medical Council shall, when making such advances, be satisfied as to the terms and other conditions of repayment by the several medical boards." The object of the second proviso was to prevent the medical board from being unnecessarily extravagant.

Lord CARLINGFORD said that the amendment was a very proper one, and he would therefore accept it.

The amendment was accordingly agreed to.

Some further verbal amendments having been introduced into the Bill, the report was received, and the Bill was ordered for the third reading.

FRIDAY, APRIL 27TH.

THE MEDICAL ACTS AMENDMENT BILL.

The Bill was read a third time.

On the order that the Bill do pass,

The Marquis of SALISBURY moved that the number of members of the Medical Board be reduced from 17 to 16 by removing the London Society of Apothecaries from the board.

The Earl of CAMPERDOWN hoped that the Lord President would assent to the amendment. The Society of Apothecaries would of course lose their power of granting licences to medical candidates, and it was therefore to be expected that their degree and diploma would not be sought after with so much avidity in the future.

Lord CARLINGFORD did not see any representative of the Apothecaries' Company in the House, and he himself did not feel in a position to present their case to the House. On the information he had obtained, he thought the claims of that body to representation on the board were of the slightest, and he was therefore prepared to accept the amendment of the noble marquis.

The amendment was agreed to, and the Bill passed.

Obituary.

DR. T. B. BARTON, OF LIFFORD.

ON Tuesday week, Dr. T. B. Barton, Surgeon and Physician to the Donegal Infirmary, lost his life by drowning in the River Foyle, near the City of Derry. Dr. Barton was sailing in a canoe, when a sudden gust caught the sail and overturned the canoe. The unfortunate gentleman was observed trying to right the boat, and failing in that, endeavouring to swim ashore. He had not gone far when he was seen sinking, being probably exhausted by his efforts first to free himself from the canoe, and afterwards to put the boat right. The deceased was an A.B. and M.D. of the University of Dublin, and had been for some time in the P. and O. Mail Service, and afterwards House Surgeon of the Maidstone Hospital.

Royal College of Physicians of London.—The following candidates were admitted Members of this College on Thursday last, April 26th:—

Fraser, Donald Manson, M.D. Aberdeen, Haverstock Hill, N.W.
Gibbons, Robert Alexander, M.D. Edin., 32 Cadogan Place, S.W.
Granville, Joseph Mortimer, M.D. St. And., 16 Welbeck Street, W.
Maguire, Robert, M.D. London, Manchester.
Parker, George William, 39 St. Mary's Road, S.E.
Sinha, Narendra Prasanna, L.M. Calcutta, 37 Gloster Crescent, N.W.
Stevenson, William Ed., M.B. Cantab., 15 Henrietta Street, W.

The following candidates were admitted Licentiates on Thursday, April 26th:—

Bloxam, George Edward, Wim'ledon Hill.
Bown, Arthur Thomas, West Combe, Evercreech, Bath.
Braine, George Marcus Panton, 7 Crossfield Road, N.W.
Cave, Edward John, Melbury Osmond, Dorchester.
Christian, John Barrow, Ashwell Station.
Crage, William Henry, Middlesex Hospital, W.
Cresswell, Francis, Winchmore Hill, W.
Gale, Arthur Knight, Fulham Hospital, Seagrave Road, S.W.
Glover, John Philip, 2 Osborne Terrace, S.W.
Goddard, Charles Ernest, 14 Cambridge Gardens, N.W.
Haynes, Walter Frederic, 63 Devonshire Street, N.
Hind, Alfred Ernest, 37 Guildford Street, W.O.
Howse, Percy W. McDowall, 74 Victoria Dock Road, E.
Jones, John Edward Evans, Matfield Park, N.

Lessey, Sandford Sobell, 4 Park Gardens, Ealing, W.
 Lewers, Arthur Hamilton Nicholas, 83 Gower Street, W.C.
 Masters, Edgar Ernest, 24 Ralinton Road, S.E.
 Mickle, Herbert, 3 Lansdowne Place, W.C.
 Robson, William Waller Constable, 25 Brompton Square, S.W.
 Rowell, Herbert Ellis, College Park, S.E.
 Sanevoshi, Yasurumi, 65 Lambeth Palace Road, S.E.
 Stone, Frederick William Stanley, Hosp. for Children, Shadwell.
 Style, Mark St. Mary's Hospital, W.
 Thornton, Henry John, Middlesex Hospital, W.
 Trinder, Alfred Probus, St. Bartholomew's Hospital, E.C.
 Unicorn, Thomas, Ramsgate.
 Yogan, James Norman, 45 Eastlake Road, S.E.
 Welch, George, St. Bartholomew's Hospital, Rochester.
 Whitworth, William, 43 Frederick Street, W.C.
 Wholey, Thomas, 2 North Side, Victoria Park Square, E.
 Williams, John Henry Hywell, Haverfordwest.

Notices to Correspondents.

Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 28 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

A. M. D.—The annual dinner of army medical officers is fixed for Friday, 25th of May, at the Ions of Court Hotel. You must apply to Surgeon-Major Don, 6 Whitehall, London.

EXPERIMENTALIST.—We would advise you to try for one of the open Scholarships of the Grocers' Company, the value of which is £250 per annum.

AN ASSISTANT.—The debate at the Medical Council more than ever confirms our view as to the iniquity of the unqualified assistant system. The chairman of the committee entirely coincided with the opinions expressed at length in this journal.

DR. STANLEY.—See editorial note on the subject in this issue.

MR. GRIFFITH.—Your information is so far correct that objections have been raised by both Colleges to the constitution of the Medical Board; and that their representations have received consideration is evidenced by the amendments introduced into the Bill when it last engaged attention in committee. To your question, how far the contemplated changes will react injuriously to the cause of education, it would be perilous just now to reply.

DR. HARRIS.—Your criticism is scarcely just. The circumstances under which the notice was written were peculiar, and could hardly have been known to you at the time, or you would have acted in a very different manner. Such conduct we still hold to be inexcusable.

DEATH THROUGH A FALL ON A NEEDLE.

La Presse Médicale reports a curious accident, resulting in the death of a little girl, three years of age. The child had picked up a needle, and was running with it to her mother when she fell upon the needle, which penetrated the fourth intercostal space, the eye of the needle alone remaining outside the wound. The mother withdrew it by means of her teeth, but the child died before medical aid could be obtained, probably from internal hemorrhage, which, gradually pressing upon the lung, brought about extreme dyspnoea.

MR. A. R. LOREY.—The normal reaction of healthy urine is acid, and you may suspect something unusual in any case where alkalinity of the excretion is observed, notwithstanding that evident signs of mischief may be wanting. Dr. Ralfé's work on "Morbid Urine" is the most suitable guide you can obtain for the purpose you have in view.

R. Y. F.—The certificate must be signed by two independent medical examiners, and would be altogether invalid if subscribed by a near relative of the patient.

DR. RANDLE.—We shall be glad to give you any assistance in prosecuting your search if you will say in what way it is to be done.

DR. H. ERICHSEN (Detroit).—Sorry we cannot further increase our exchange list; it is already too large.

THE DISMISSAL OF POOR-LAW MEDICAL OFFICERS.

A DEPUTATION of Poor-law Guardians of Birmingham waited upon the President of the Local Government Board on Friday last to ask for the power of dismissing their officers without any restriction whatever on giving them reasonable notice. Sir Charles Dilke replied that a Consolidated Order would contain all the powers that they sought for, and this order would be issued before the end of the year, and be applicable throughout the country. Since this answer was given, the President of the Board has, we are glad to be assured, found reasons for modifying his reply, and no change will therefore be made in favour of the guardians' preposterous request for unrestricted dismissal of medical and other officers of unions. Had Sir Charles Dilke persisted in giving the power sought, we could have promised him the unqualified opposition of the *Medical Press* and every Poor-law medical officer in the United Kingdom.

DR. BURTON (Liverpool) is thanked for his valuable paper on "Puerperal Eclampsia," which shall appear in an early number.

DR. BRUCE and DR. WILLIAMS are thanked for their notes.

WARTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

J. P. says: I shall feel obliged if you would kindly mention in next

issue an effectual means of removing a wart from the face. I have tried acid acetic, sal. ammoniac, and a few other ordinary remedies; but the party objects to argent. nit., or any application that may leave even a temporary stain.

[Try acid nitrate of mercury with caution.—ED.]

A. J. HARVEY.—Your letter will appear in our next.

MEETINGS OF THE SOCIETIES.

WEDNESDAY, MAY 2ND.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—At 8 p.m., Nomination of office-bearers for the ensuing session.—Deputy Surg.-General Joseph Ewart, On the Causes of the Excessive Mortality among the Women and Children of the European Army of India.

OBSTETRICAL SOCIETY OF LONDON.—At 8 p.m., Specimens will be shown by Dr. Mansell-Moullin and others.—Dr. Basch, On a Case of Extra-Uterine Pregnancy resembling so-called Missed Labour.—Dr. Braxton Hicks, On the Behaviour of the Uterus in Puerperal Eclampsia as observed in two cases.—Dr. Herman, On a Case of Acute Gangrene of the Vulva in an Adult, with remarks.

THURSDAY, MAY 3RD.

HARVEIAN SOCIETY OF LONDON.—At 8.30 p.m., Dr. Broadbent, On Two Cases of Solution of Calculus in Kidney and Bladder.—Mr. G. F. Field, On the Treatment of Catarrhal Deafness in Children.

ACADEMY OF MEDICINE IN IRELAND (Sub-section of Anatomy and Physiology).—At 8.30 p.m., Papers: Prof. Macalister, On some Processes of the sphenoid Bone.—Prof. D. J. Cunningham, Further Observations on the Development of the Suspensory Ligament of the Fetlock in the Horse and Roe-deer.—Mr. P. S. Abraham, Note on the Musculus Sternalis.—Mr. J. F. Knott, On the Accessory Nerve of Willis.—By card: Mr. P. S. Abraham, Sections of various Supra-renal Capsules.

FRIDAY, MAY 4TH.

ROYAL INSTITUTION.—At 8 p.m., Mr. E. H. Foott, On Weather Knowledge in 1883.

SATURDAY, MAY 5TH.

ROYAL INSTITUTION.—At 8 p.m., Mr. A. Geikie, On Geographical Evolution.

TUESDAY, MAY 8TH.

ROYAL INSTITUTION.—At 8 p.m., Prof. McKendrick, Physiological Discovery.

Vacancies.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Resident Clinical Assistant. Applications to be sent to the Secretary not later than May 14th.

Royal Alexandra Hospital for Sick Children, Dyke Road, Brighton.—House Surgeon. Salary, £80, with board and lodging. Applications to the Chairman of the Board before May 16th.

St. Mary's Hospital, W.—An additional Surgeon in joint charge of Ophthalmic out-patients. Applications to be sent to the Secretary on or before May 19th.

Western General Dispensary, Marylebone Rd., N.W.—Resident House Surgeon. Salary, £120, with furnished apartments, &c. Applications to be sent to the Secretary on or before May 7th.

Appointments.

GAUNT, J. P., M.R.C.S., Medical Officer for the Alvechurch District of the Bromsgrove Union.

GORDON, A., L.A.H., L.M., Resident Medical Officer to the Grand Canal Street (Dublin) Dispensary.

HEALD, R., M.R.C.S., Medical Officer for the Hardingham District of the Mitford and Launditch Union.

HORNE, T., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the Ash District of the Eastry Union.

KRAY, J., M.B., C.M., Junior Assistant Physician to the Crickton Royal Institution, Dumfries.

KENT, W., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer for the Buddalph District of the Congleton Union.

MAIN, A. J., M.D., L.R.C.S.Ed., Medical Officer for the Leabury District of the Alnwick Union.

FOLLARD, F., F.R.C.P.Lond., M.R.C.S., Physician to the Children's Infirmary, Liverpool.

SPENCE, Dr. W., Resident Physician to the Royal Hospital for Sick Children, Edinburgh.

STIRLING, Dr. J. H., of Edinburgh, Honorary President of the Glasgow Independent Club.

STONE, G. L. B., Medical Officer to Lucan and Linnip Dispensaries, Cambridge Union.

VINCENT, O., F.R.C.S.Ed., Consulting Surgeon to the City of London and East London Dispensary.

Deaths.

BARTON—April 24th, drowned, by the upsetting of a boat, on the River Foyle, Travellers Boyne Barton, A.B., M.D., L.R.C.S., Surgeon of the Donegal County Infirmary, Lifford, aged 77.

BULLEY—April 21st, at the Royal Berkshire Hospital, suddenly, Francis Arthur Bulley, F.R.C.S., of Reading, aged 74.

HICKES—April 17th, at Cheddar, Thomas Hickes, M.B.C.S., late of Gloucester, aged 77.

OWENS—April 18th, at Plalstow, Essex, of rapid consumption, John Owens, M.D., L.R.C.S.I., second son of Sir George B. Owens, J.P. of Dublin.

REDMOND—April 21st, at 50 King Street, Waterford, Dr. John Joseph Redmond.

RICHARDSON—April 29th, at his residence, 22 Ely Place, Dublin, Benjamin Wills Richardson, F.R.C.S.I., aged 64.

STEEL—April 7th, at Montrose, Henry Steele, M.D., aged 43.

TUKE—April 20th, at Bournemouth, William Samuel Tuke, M.R.C.S., eldest son of Dr. D. Hack Tuke, of London, aged 82.

WITT—April 23rd, at Lavender Hill, Charles Witt, M.R.C.P., M.R.C.S., late of Spring Gardens, S.W., aged 85.

ON THE DIFFICULTY OF DIAGNOSING TRUE SYPHILITIC DISEASE IN WOMEN, AND THE NATURE OF ITS CONTAGION. (a)

By C. H. F. ROUTH, M.D. Lond.,
Fellow of University College, London.

I WISH it to be clearly understood, Mr. President, at the outset of my paper that these remarks eminently refer to women. Of men I shall speak only incidentally, and in so far only as their mention is necessary to explain effects on syphilis as it occurs in women.

Secondly.—I wish to state also that I do not mean this essay to be, except incidentally, an attack on our Contagious Diseases Acts. I would rather consider the question in its full scientific bearings, however strongly I may feel on it morally. In doing this I shall also quote largely from foreign statistics and opinions, so far as they appear to me to throw light on the question, a task considerably facilitated by the researches of M. Yves Guyot in his classical work on Prostitution. This work has made much noise abroad, and to it I am particularly indebted for much of the evidence which I bring forward to-night. I shall endeavour to state my views moderately and respectfully; but as I know the subject is one which generally is very exciting to the profession at this time, I trust a kindly and scientific spirit will animate our proceedings, and that I may be listened to with patience and forbearance.

It behoves me, however, to premise by stating what I understand by syphilitic disease. Nor does it seem possible to omit so doing, because the opinions as to what is and what is not syphilitic disease have so varied during the forty years that I have been in the profession, that in reading different authors on the subject we scarcely make out that the same disease is meant.

When a young man I was taught there were four kinds of chancres—the hard, or indurated, the soft, or superficial

ulcer, with raised edges, the phagedenic, and the sloughing. Later Ricord held to the opinion of Chomel and Dupuytren that the soft and hard chancres were identical, and both needing mercury for cure. In 1859 the dual theory that the soft chancre and hard chancre were different diseases came into vogue, the former never producing, the latter almost always producing secondary symptoms, as established by Bassereau, Rollet, Diday, and Fournier, and to these Achille Vintras, Guerin, and others, opinions in which most if not all French surgeons, including Ricord, now concur. Amongst ourselves, we have the most contradictory statements, if we may judge from the late proceedings of the Contagious Diseases Acts Commission. Herein Surgeon Myers, Dr. Barr, Mr. J. Hutchinson, the late Sir W. Ferguson, Mr. Syme, Mr. Acton, Mr. Savory, Sir J. Paget, Mr. Outler, Mr. Samuel Lane, Mr. Gascjoen, Mr. J. R. Lane, Mr. Solly, Mr. Erichsen, are all stated to believe in the existence of but one poison; whereas, on the other hand, the names of Professor Longmore, Professor Aitken, Patrick Watson, Henry Lee, Sir H. Thompson, Dr. Nevins, John Barton of Dublin, Dr. Drysdale, Mr. Berkeley Hill, and many others, are instanced as holding the opinion that there are two varieties, one only of which, the hard chancre, is capable of infecting the constitution. Surgeon-General Lawson also inclines to this belief.

Abroad, however, the belief is almost universal in favour of the dual theory, as before stated.

It is not for me to decide between these two parties. Yet this discordance of opinion appears to me quite susceptible of explanation. A sore may be a mixed sore, *i.e.*, upon the same person you may have a hard, a soft chancre, and gonorrhœa. Indeed, there is no more reason for believing that gonorrhœa can co-exist with a chancre in the male urethra, as Ricord proved, than that you may have both equally present in the uterine canal and vagina. A true syphilitic sore may exist in the former. It is certainly not unusual to find chancres on the hard cervix, and here surely their hard character could not be eliminated from the ordinary hardness of the cervix itself, which we know even in non-syphilitic cervixes is unusually hardened, and thus a true chancre could possibly be mistaken even in

(a) Read before the Medical Society of London.

this position for a small ulceration. But both Dr. Matthews Duncan and myself have shown that there is often a suction upwards of the vaginal secretions into the uterine canal; and if so, why should not a chancre develop there, if a woman have received the secretions of an infected man in her vagina. When, however, I find Dr. Berr (who for thirteen years had been examining surgeon at Aldershot, *i.e.*, from May 1, 1868, to March 30, 1881, and during that period conducted 54,848 examinations) stating that all the sores which one sees in a prostitute may be followed by secondary symptoms, and so are to be called cases of primary syphilis (4666 and 4667, Report of Contagious Diseases Acts Committee), and again, Mr. Lane asserting that you can inoculate a patient from a hard sore on himself or another syphilitic patient (2675) and produce a soft sore, and on the other hand, in France, where inoculation has been largely practised even on non-syphilitic patients, and inoculation from a hard sore always produced a hard sore, and from a soft sore always a soft sore, I confess I am somewhat perplexed.

Still, on mature reflection I think I must side with the French and foreign experimenters, and for the following reasons: Their inoculations were not only more numerous but frequently practised on non-syphilitic subjects. Mr. Lane's inoculations, and those of many other English experimenters were practised on men partly syphilitised, or, at least affected at the time with true syphilis, and he himself admits (2506) that a woman at any rate is protected for a time, a considerable period once syphilitised, although she may under these circumstances become infected with a soft sore. But Mr. Henry Lee has pointed out special differences in the soft sore produced by inoculation from a hard sore in a man at the same time affected with true syphilis, from the sore produced by inoculation of a soft sore, whether in a syphilitised or unsyphilitised person. The soft sore is neither a primary sore, nor a soft sore proper, there is an increase of substance instead of a decrease, it wants the sharp outline of the infecting sore, in fact, it is very like a blind boil. It is a different kind of inoculation to either the other two (1008). Mr. Lane's soft sore produced by inoculation of a hard one is not the true soft sore, as Mr. Lee described it. The two are totally different. Ricord's justification of himself is, however, the best commentary I can give on the error in Mr. Lane's experiment. "Never, gentlemen," said Ricord before the Academy of Medicine, Nov. 1, 1881, "was I willing to inoculate a non-syphilitic person with a lancet charged with syphilitic pus. Hence originated my error in reference to the question of secondary accidents. It was necessary to inoculate healthy persons with syphilitic pus. I never could bring myself to do so. Others were more daring and succeeded." My own conviction is, therefore, that held, I believe universally by French medical men, that there is but one true syphilitic and venereal sore capable of contaminating the system. The other is a purely local affection, a pseudo-syphilis, chancroid, or dirt sore.

I think it is very much to be regretted that in the returns now made in the army and navy the distinction between a truly syphilitic hard sore and a soft one is not made. Two reasons have been alleged that, as both incapacitate a man whose military service is needed, it matters not whether the distinction is made or not. If so, why not place all the venereal diseases, including gonorrhoea, orchitis, &c., under one name. Also such diseases as bronchitis, pneumonia, pleurisy, &c., each deprive men from rendering their accustomed service, under one general appellation also. This has not been done, and we see the advantages of this distinction scientifically. The other objection made is that there is an alleged difficulty in practice in accurately diagnosing some sores, specially mixed sores, on admission to hospital. But surely a very few days, and while the patient is in the hospital, would clear up the difficulty. Besides this objection would apply to most doubtful diseases when first admitted in any hospital; time clears up the case. Then how is it that our French colleagues can make it? Look at Mauriac's returns to which I shall presently refer. Must

we say that our army surgeons are less capable than our neighbours? I trow not; for the distinction was formerly made in the army reports. Why not now? Is it because the decrease of primary sores would be found only in dirt sores, which habits of cleanliness alone if well enforced on the soldier would prevent? If so, surely here red-tape and routine, and exact science are in antagonism.

TABLE IV.—MAURIAc's RETURNS.

Hôpital du Midi.

After eighteen months' inquiry, noting every case referable to diseased women (*i.e.*, in 1869 and first half year of 1870.)

Out of 5,008 diseased, infecting source was determined in 4,745.

Variety of disease.	By Prostitutes.					
	80,000. Unlicensed.		1,706. In Brothels.		2,525. Isolated.	
	No.	pr 1000.	No.	pr 1000.	No.	pr 1000.
Soft Chancre ... (4745)	4,012	134	430	170	302	251
Soft Chancre ... (579)	482	14½	59	23½	58	48
True Syphilis ... (1633)	1,414	47	139	55	80	66½

Next as to their relative frequency. Sir W. Muir states the number of syphilitic to non-syphilitic sores is one-third. This statement is confirmed by Mr. Lawson, and Mr. Bond tells us that one-third of the sores he sees at Westminster Hospital are syphilitic. (Bouth, *Evid.*, 289-291.) And this seems to be the general opinion, although some variations have been observed abroad. In Paris the figures are reversed, 1 soft sore to 2·8 hard, and in many other cities the proportion is higher. This great preponderance of the non-infecting sore in England is of great importance when we come to consider the effect of regulations of vice on true syphilis.

II. *What is a true chancre?* Now, I will quote from M. Fournier's "Lessons on Syphilis" who you are aware is a distinguished syphilograph, and a great advocate for contagious acts. "A chancre," says he, "at its initial period is so little that I can without exaggeration qualify it in the following manner, *viz.*, the smallest, most superficial, most benign, most insignificant of all possible erosions. It is not in fact anything, so to say, it is less than nothing. To such a degree in fact that the first time or times that one is called to examine a chancre in this form and early period, one is always deceived, and it is impossible *not* to be thus deceived.

"What is it later? A small erosion resting on a wider base.

"And later at its summum of development? A limited sore, in general, simply erosive, indolent, with no tendency to extend or to deepen itself, something like a large herpetic spot, something like the most superficial and benign of traumatic lesions.

"Finally, this erosion heals and cicatrices, and all is said. This constitutes all. The chancre is and nothing more.

"This accident is so trifling that formerly it was believed to be exceptional in a woman, and even these have been written to prove that it does not exist in them at all. Nothing is more false. It is more frequently extra-genital in the woman than in the man; so should be looked for outside the sexual organs. It is very rare in the vagina, frequent in the cervix uteri; shows itself on the breast and anus.

"It follows that the chancre in a woman is rarely made out—*de visu*. The evolution in nearly all cases takes place in an insidious manner, and without any kind of pain."

Mr. Simon says, in women primary venereal ulcers and other local states capable of infecting with syphilis, not

only very often pass unnoticed by the patient herself, but have often been overlooked in examinations made expressly for their discovery. Professor Aitkin, in his work on the "Science and Practice of Medicine," says, speaking of women: "A hard chancre or sore in them is exceptional, and when it does occur it remains small, is ill-developed, and readily overlooked even when searched for with great care, aided by a vaginal examination with the speculum."

Dr. Drysdale speaks to the same effect in his evidence before the Contagious Diseases Acts Committee. Their primary (true syphilitic) lesions can be very rarely found in a hospital. A woman may have a very slight sore, so small that you would not remark it, but she may be syphilitic at the same time; and then, with all his well-known experience, tells us: "I have sometimes spent a very long time—perhaps ten minutes—to try if I could discover any reason for the enlargement of the glands in the groin, and have not been able to find anything, and then afterwards there has been syphilis" (475 to 497).

Mr. Henry Lee states, in answer to Dr. Farquharson (1022):—"I have already stated that the primary sore of real syphilis gives very little pain; it has a period of incubation from some ten days to three weeks, and the woman would not present any objective symptoms during that time. It would be no use examining her then, and even then it might be very difficult to detect it."

Pardon me if I here remark that a great objection has been taken to a guess made by myself before the Contagious Diseases Acts Committee that, out of ten cases affected with true syphilis in a woman, in one-half it would not be detected. This guess, which I was forced to make by Mr. O. Morgan, has been given out as a deliberate opinion, and yet I believe I am not far wrong. Mr. Henry Lee does state, and deliberately so, that more than one-half the cases of real syphilis are communicated by secretions of patients who have syphilis, and do not present any primary lesion which should be characteristic of syphilis; "and indeed, unless," as he also adds very properly, "we examine a woman *all over*, and she gives a correct history of her case, I do not see how the truth could be got at by mere local examination." An examination thus complete may be made, although very exceptionally in a private case, where strictly required by the patient, but would not and could not be tolerated in the official examinations enforced on prostitutes, although from the evidence of Professor Sigmund, of Vienna, stated to Messrs. Belhumme and Martin that in Austria a girl was not allowed to leave the cabinet of the officer of health until she had been examined from *cap à pied* (Guyot, p. 294). In England this never could be permitted.

And this difficulty is set forth in a more graphic manner, perhaps, because the opinion given thus comes from staunch supporters of contagious diseases acts. The infrequency of the examinations of females is distasteful to these gentlemen. And why? Because it is so often useless. In France, you are aware, it is made once a fortnight. But Ricord asks that it should be made every three days, Messrs. Raten and Sandwith every four days, M. Langlebert at least twice a week; and, more than this, M. Lancereau exacts that not only it should be done every two days, but that the woman should not be examined immediately they present themselves, but locked up in some special locality for some hours, deprived of all water, and then should be examined while completely naked; while Mirour, himself a writer in a work on prostitution, states that every woman who has had syphilis should be compelled to submit to a daily examination for eighteen months.

Now, what do these opinions prove but the conviction of all advocates of contagious diseases acts that no plan hitherto devised for the examination of women is of any avail, because in most instances true syphilis in a woman escapes the closest examination? I think, therefore, I have proved my first proposition—the difficulty of detecting true syphilis in a woman.

ON THE WINTER HEALTH RESORTS OF THE ALPS.

By E. SYMES THOMPSON, M.D., F.R.C.P.,
Senior Physician to the Hospital for Consumption, Brompton.

(Concluded from page 377.)

DURING 300 consecutive journeys over the passes this winter to and from St. Moritz of which notes have been taken, only four have been followed by catarrh, owing no doubt to the care of the travelling companions and the watchful attention of those who have provided extra and fur-lined boots for the sleigh journeys.

There is really a greater danger of chill to the patient when he has reached his destination, and therefore a still greater need for a watchful medical attendant and self-denying sensible companions who will forego some pleasure rather than lead the invalid into temptations which he has difficulty in resisting. Before April comes, many of those who have gained and are gaining steadily are affected by a widespread, often fatal epidemic, which may be called "love of change and novelty fever." This fever has lately attacked many who, instead of being content to go on in the dry bracing air until "snow melting" comes, start off sight-seeing to the plains, or to the lakes, where they find weather quite as trying as that of England in March and April, without home comforts and without means of escaping from the dangers around.

Now-a-days people expect to be cured of chronic complaints at express speed. When I first knew Davos and the Engadine, the steady, plodding German and Dutch patients who populated them repaired thither in May or June, remained till the following April; and, if a return was then deemed advisable, took a few weeks' holiday at some very quiet place—no scampering about sight-seeing—and were back again contented to be able to regain their health at the sacrifice of one, two, or three seasons. This is now all changed, the only pity is that the malady has not changed too. It, alas! remains the same; and the patients reap the fruits of their impatience and instability of purpose.

Cases of anæmia and chlorosis do only fairly well in the Engadine in summer, and in winter also. When hysteria is present the air is apt to prove too exciting and irritating, and thus nervousness and sleeplessness are increased. Persons prone to flushing or to "flushes and chills," do not flourish; nor do those subject to congestion or nervous headaches. It is seldom wise to send sufferers from neuralgia to snowy regions, as the neuralgia is apt to come on and continue in cold air; and thus such patients keep in doors, and lose the benefit of the sun.

Phthical patients having very excitable temperaments are less likely to gain good than the more lymphatic class; yet the torpid and indolent who prefer bed and the fireside to the open air cannot gain much from any climate treatment.

This winter I have sent two chlorotic patients to St. Moritz. In one of these the blood was so poor and the circulation so languid that cramps occurred in skating, which interfered much with exercise and delayed progress. In the other case, improvement set in at once, and the patient is now stronger and better than for years.

Jaundice and liver affections, constipation and consequent piles, are common in the Alps. Chronic skin diseases are increased, also rheumatic affections. Young people, children especially, do well; old people do not. Teeth degenerate in the Alps; a visit to the dentist should precede one to the Alps. Artificial eyes are a source of trouble, by communicating cold to the orbit. As regards phthisis, it is almost needless to say that like other health resorts the Alps afford their most favourable results in cases of threatened lung disease.

Cases of characteristic, hereditary, tubercular disease, even where the physical signs are not very manifest,

do not, however, show such good results as those in which the local evil is manifest but limited, with surrounding sound lung. The disease may, indeed, be advanced and a cavity exist on both sides, yet benefit often comes; and I have seen several cases of this kind. Among the cases most markedly benefited are those of chronic pleurisy or pleuro-pneumonia in which the effused products have proved slow to resolve. Effusions are said to disappear speedily, and I have observed that lungs bound down by fibrous deposits lose their hard percussive note; permeability and elasticity return; the size of the chest increases, and the air enters freely, puerile breath sounds taking the place of feeble breathing. The circulation through the lungs being freed, the heart's action is relieved, its pulsations become less frequent, and the tendency to catarrhal complications following exertion and exposure to cold is eventually lost. My attention has been drawn to the fact that, if the pulse becomes quiet, the irritability of the heart lessens, the temperature falls, and it is safe to prognosticate improvement; if the temperature remains high for six weeks after arrival, and shows no sign of decided reduction, then it is best to try another change of climate. The quick pulse may generally be traced to obstruction in the pulmonary circulation. It was pointed out by my late father, Dr. Theophilus Thompson, that the rapid pulse of phthisis is not reduced by recumbency as it is in health. The rarefied air, by leading to full chest expansion, frees the pulmonary capillaries, and thus the necessity for hurried action of the right heart is removed; with the reduction in the pulse rate a diminution of pyrexia occurs, and catarrhal complications become less severe and lasting.

Cases of general bronchitis, whether acute, sub-acute, or chronic, are, however, seldom benefited unless there is limited localised consolidation, the result of pneumonia, pleurisy, or bronchitis; the remaining portions of lung being healthy. If this is the case, Alpine climates often do great good, the hardened portions of lung become pervious, the surrounding healthy parts expand, and so the dyspnoea is lessened and paroxysmal asthma no longer occurs.

Asthma, if associated with localised bronchial affections, is often very favourably affected; but if due to emphysema and general bronchitis improvements cannot be counted upon.

My friend and late colleague, Dr. Marcet, has shown in his recent interesting book on "Southern and Swiss Health Resorts," that inflammatory diseases of the chest are frequent among the Swiss mountains, and that at Chamounix one-fifth of the mortality is due to pneumonia.

As regards bronchiectasis, improvement is found to be very slow at Davos, as elsewhere. Rapid gain must not be expected.

Pure spasmodic asthma does well at St. Moritz in winter, as in summer—perhaps better in the former than the latter, on account of the greater equability and dryness of the air. One young fellow, who in England could seldom walk up two flights of steps without resting, was constantly to be seen skating and tobogganing, and never for a moment breathless, although the sounds of the chest showed that much local disease remained.

Hæmoptysis is not uncommon, but is mainly traceable to the undue exertion taken by patients who fail to attend to the precautions laid down. Cases of hæmorrhagic origin are among the most favourable—a result attributable in part to the non-hereditary nature of these cases, and next to the pure aseptic air rendering the after effects of blood effusions into the lung less injurious, and less likely to set up pyrexia than at low levels with impure air. In one case which occurred at St. Moritz, hæmoptysis followed running to the hotel and then hurriedly stooping to adjust a lady's skates. In another it followed dancing; and in a third, exposure in the late evening to chilly air.

There is no evidence to show that the rarefied air causes leakage by expanding the lung and opening out weak vessels. Where the amount of damaged lung is large there the sense of dyspnoea interferes with exertion, and so lessens the danger of hæmorrhage; in all other cases the exhilaration, by producing a sense of lightness and ability for exertion introduces an element of increased danger.

Dr. Ruedi, of Davos, watches his patients like a cat watches a mouse, or as he says, "like a policeman a 'ticket-of-leave man.'"

There is, perhaps, no health resort where the necessity for ceaseless vigilance on the part of the doctor and of implicit obedience on that of the patient is so essential. The absence of painful sensation in lung disease leading to unwillingness to accept rules for guidance is familiar in every climate; but where a sense of buoyancy and ability for exertion is a special feature in the effect of climate, the danger of excessive exertion then becomes so great that it will probably continue to frustrate the best and most watchful efforts of the resident physicians, and will cast an undeserved discredit on the climate.

In one of the most favourable cases I ever sent to Davos—a case in which Dr. Ruedi expressed, and with well-grounded confidence, the most hopeful prognostications—the patient walked for six hours, dinnerless, over an exposed pass in a strong wind, shivers, lung congestion and consolidation followed; and in three days he was dead.

If, therefore, a patient shows an unwillingness to submit to necessary restraint, and a readiness to be tempted to undue exertion, this alone should make us very careful in sending such an one to the mountains; for there the danger of damage is far greater than in the Riviera or South of England.

On the other hand, one of my patients failed to gain full benefit, not because his disease was unsuited to the climate, but because he would smoke and drink, would take no exercise, and refused to see the force of the doctor's directions.

My friend and colleague, Dr. C. J. Williams, in his valuable record of "Cases of Phthisis as treated at High Altitudes," in the *Lancet* of August 9th and 16th, 1879, states that, "when at Davos, in the winter of that year, he was surprised at the large proportion of pyrexia among the phthisical patients, which, considering the limited amount of disease (and that in an incipient form) which prevailed, is unusual, and different from the common experience in England. The influence which so powerfully stimulates digestion exercises a corresponding influence on the inflammatory process, and converts what in England would be a passive congestion with low temperature into a well-marked pyrexial inflammation."

My own observations at Davos and the Engadine this winter do not confirm this view. While Dr. Williams was struck with the disproportion between the pyrexia and the amount of lung disease, high fever occurring when the lung was but slightly involved, I was impressed, and this in a large proportion of the cases, with the absence of fever, and, indeed, of all other symptoms of illness, even in cases of extensive and advanced disease.

It is true that I saw two or three cases in which pyrexia was unduly marked, exactly as Dr. Williams described, and in which the severity of the fever led me to expect far more serious resulting lung damage than actually occurred, but these cases were quite exceptional.

If Dr. Williams had been with me in January last, I am sure he would have concurred in the opinion that it would have been hard to find elsewhere so many cases of pronounced, and often extensive and advanced, lung disease with so little pyrexia or constitutional disturbance. It may, however, be accepted as a fact that febrile action, when it occurs in the mountains, is of a more active kind than on low levels; and further, that

when wisely treated, it more quickly yields, and leaves behind less serious results.

Chest Measurement.—The chest measurements published by Dr. C. J. Williams in the "Transactions of the International Medical Congress" are more remarkable than in my own cases. It is true that the results are extraordinary, after pleurisy, but in cases of phthisis without complication I have not made out that the increase is greater than $\frac{1}{2}$ or $\frac{3}{4}$ of an inch. Many patients have not, before going out, been accustomed to active mountaineering, which, besides bringing the whole chest into play, causes increased development of the pectoralis and latissimus dorsi muscles.

Again, my cases have not been those of growing lads or lasses who naturally increase in girth, as in other directions during the expansion of their frames.

In taking cyrtometric trainings it is exceedingly difficult to take observations accurately. The difficulty is less when the callipers are used; they are quickly adjusted. It is easy to fix with accuracy on two bony points, such as the spinous process of a certain vertebra, and in front on a rib. The amount of expansion of each lung may be quickly and accurately determined; and by the use of the callipers you avoid errors of chest measurement due to variation in muscular enlargement and contraction.

Again, as regards *weight*, I have found an increase of weight at first if the patients are kept very quiet on arrival; but it has seemed that the exceeding dryness of the air, which causes a loss of moisture from the body, does not allow of that marked increase of weight which the creation of muscular vigour might lead one to expect.

It is, however, to be observed that many who have gained but little weight during their stay, begin rapidly to gain weight on returning home, as an athlete in training rapidly puts on weight immediately after the contest—when he is no longer limited in fluid food.

That great benefit constantly accrues from the mountain treatment is, to my mind, undoubted; but it is not safe to count upon permanent arrest, still less to look for restoration to health in advanced cases after a single winter.

During my visit to St. Moritz and Davos in January last, I had an opportunity of examining cases of phthisis in every stage, and could not fail to be impressed with the marked advantage accruing in almost every instance. In one case of advanced phthisis, with excavation in one lung, and softening in the other, chilblains interfered much with exercise, and prevented improvement which, however, could hardly have been expected under any circumstances.

In another case, the whole of one lung was converted into an immense amphora, but the sound lung had encroached on the space vacated by the diseased one, and the patient, a girl of 19, was able to walk slowly to the rink and spend four or five hours in the sun, having her luncheon brought to her in a shaded corner of the rink which had on the north, east, and west a bank some 10 feet high, which not only sheltered from wind, but reflected the solar rays.

I examined cases in the first and second stage of phthisis, in which complete arrest had occurred; the pulse was quiet, temperature normal, and the patients skated and tobogganned for hours daily.

In a case of chronic basic cavity with fetid breath, although an attack of jaundice checked progress and led to some loss of flesh, no fat being taken till the obstructed duct was free, yet the remaining lung tissue being fully expanded the patient was able to walk, and even run up hill without dyspnoea, and the chest expansion was four inches.

In a case in which softening, and a small cavity (doubtful) had existed at the right apex, I could find nothing but some woodenness of percussion with prolonged expiration and conducted heart sounds above the right clavicle. Chest measurement showed an in-

crease of nearly an inch. He had gained between six and seven pounds in weight, as well as in muscular tone, for he took much exercise.

One patient impressed me much, of consumptive family, with all the characteristics of a phthisical constitution, rapid pulse, high temperature, hectic, cough, night sweats, loss of flesh, purulent and pearly expectorations, and occasional hæmoptysis. I was prepared to find evidence of advanced and advancing disease. The physical signs confirmed this anticipation. Besides the cavity and softening on one side, there was evidence of recent softening on the other, and reason to fear that a new outbreak had occurred, which would leave the patient in a worse condition than before.

Dr. Ruedi, however, gave a favourable prognosis, and on the strength of a previous rally from an acute exacerbation, confidently looked forward to speedy amendment.

The reports I now receive confirm this favourable prognosis. The temperature is now normal, the pulse quiet, 90, not 120, the night sweats have ceased, and the moist sounds have been replaced by dry ones.

March 2nd, 1883.—Dr. Ruedi reports: He is now in his normal condition; still, the right apex does not expand so well as before.

This replacement of the signs of softening by those of a dry kind, which, indeed, we frequently see here, is so universal at Davos, that it is confidently looked for and promised by the local doctors.

One cannot avoid the conclusion that to guide a case of phthisis successfully through the various stages is a much easier matter in the higher Alps than in England—easier, I believe, than on the Riviera or at sea.

On the other hand, more than ordinary caution and watchfulness are needed if the doctor is to preserve the patient from the dangers of an exhilarating atmosphere, always tempting the invalid to presume on his powers and attempt more than his strength justifies.

In placing a patient under Dr. Ruedi's care, we may be sure that this watchfulness and judgment will be exercised to the full. In Dr. Holland, of St. Moritz, implicit reliance may also be placed. The manner in which he has organised the arrangements for the patients, and has kept a hundred people in cheery contentment during an unusually trying season does him infinite credit. My warm thanks are due to both of these accomplished physicians for much of the information contained in this paper.

On taking all the cases of phthisis together, those seen at Davos and St. Moritz, I find a total of 6 cases in the 1st stage (5 males and 1 female). In the 2nd stage, 14 cases (11 males and 3 females). In the 3rd stage, 14 cases (9 males and 5 females).

Of the six 1st stage cases 5 improved and 1 (female) remained unaltered. Of the fourteen 2nd stage cases, 11 improved, 2 remained stationary, and 1 died. Of the fourteen 3rd stage cases, 9 improved, 2 are stationary, and 3 have died.

It would be impossible for any one to see such cases as these without being convinced that in an unusually large proportion, disease is arrested.

A NOTE ON THE NEW HYPNOTIC PARALDEHYDE.

By F. J. B. QUINLAN, M.D., F.K.Q.C.P.,

Professor of Materia Medica and Therapeutics, Catholic University;
Examiner in same, Royal University of Ireland.

PARALDEHYDE, which is one of the isomers of aldehyde, had, like chloral, been long known to chemists before it was applied to physiological experiment by Cervello. It is a colourless fluid of a strong and penetrating ethereal odour, and of a very acrid and enduring taste. Its formula is $C^6 H^{12} O^3$, and it mixes with water with sufficient freedom for pharmaceutical purposes. I have tried

it on myself and on some patients with satisfactory results. If it be taken at bed-time, and the recumbent position immediately assumed, the same sensation as that arising from chloral hydrate immediately ensues—viz., a feeling as of cold water flowing through the posterior part of the brain towards the medulla oblongata; and this is immediately followed by quiet, dreamless, and refreshing sleep. The action of paraldehyde closely resembles that of chloral with the exception that it appears to have no depressing action whatever on the heart. It does not interfere with the secretions, except that of the kidneys, which it sometimes seems to increase. It does not cause headache or nausea. Further clinical experiment is desirable to show whether, like chloral, it in some persons loses its effect, and has to be increased in quantity. The dose for adults is from thirty to sixty minims; and its principal drawback is its acrid and persistent after-taste, which is principally experienced in the pharynx. This, however, can be overcome by the following formula:—

R. Paraldehydi, ℥30;
Aque ad oz. 1½;
Syrupi aurantii, dr. 2;
Spt. chloroformi, ℥30;

M. Fiat haustus. Horâ somni sumend.

If the quantity of paraldehyde be increased the same must be done with the spirits of chloroform. Like many other hypnotics, complete quiet after administration is necessary to its successful action. It is a remarkable fact that chloroform, chloral, and paraldehyde were lying upon the laboratory shelf for years before they were found to be agents of great therapeutical value. It is likely that other substances are in the same position.

Clinical Records.

ST. MARY'S HOSPITAL.

Strangulated Inguinal Hernia (Entero-epiplocele)—Operation—Excision of Omentum—Recovery.

Under the care of Mr. NORTON.

From Notes by Mr. CROSSE.

E. C., set. 35, had had an inguinal hernia on the right side for sixteen years, but when down had always been able to reduce it by application of hot flannels. On the 2nd of April, at 10 o'clock in the morning, the hernia came down, and he was immediately taken with great pain in abdomen, and continued sickness. At 1 o'clock he was seen by Mr. Norton, who found the hernia so large and tense, the local pain and the general suffering of the patient so great, that he decided to operate at once, and not to attempt to return the hernia, without opening the sac, even if such were possible.

Operation.—The tumour had a very marked constriction at its upper third. On opening the sac below this constriction, no fluid escaped, the sac being tense upon the contained viscera, which also were black from intense congestion, but not damaged. The constriction referred to was derived from the intercolumnar fibres, and on being severed exposed the upper sac, which contained dark fluid. The strangulation, which was in the neck of the sac, now being cut through, the intestine was returned. A mass of omentum, about 1½ oz. in weight, which was found to be adherent to the fundus of the sac, and which, had it not been adherent, was not in a fit state to be returned, was doubly ligatured and removed, the pedicle being placed in position to occupy the mouth of the sac. The operation was conducted with strict antiseptic measures. In the evening the temperature was 101.5°, and on the following day 102°. He was thirsty and uncomfortable.

On the 4th he was vomiting persistently, the abdomen distended, painful to the touch. Pulse 118, and respiration 30. Peritonitis was now suspected. A poultice was ordered over the whole abdomen, and a mixture, containing tr. opii, ℥ij. and vin. ipecac, ℥ij., to a drachm of water, every half-hour. The effect of the medicine was very marked. The patient was being exhausted by vomiting every few minutes through-

out the night and morning, and this was arrested by four doses.

Opium was given to the extent of three grains in the twenty-four hours until the temperature fell and the signs of peritonitis disappeared, which was about the fourth day.

On the 5th there was no sickness, but distension of abdomen was great, and the patient appeared anxious and dusky faced, complaining that he felt unable to breathe. To overcome this, an enema of turpentine was ordered, which brought away much flatulence, and gave great relief.

On the 6th sickness again returned, accompanied by hicough, both of which were relieved by a subcutaneous injection of morphia.

On the 9th flatulence had almost entirely disappeared; no pain in the abdomen, even with considerable pressure. Pulse 80, and temperature 98.4°.

The diet had been chiefly beef jelly and cold water. No milk had been allowed during the first few days on account of the sickness.

The wound had been dressed with lint and carbolised oil, the antiseptic dressings having to be discarded in consequence of the poulticing required. Suppuration of the omental pedicle took place, and the wound granulated up and closed in by the 27th.

The temperature was normal by the 10th, and continued so throughout.

The points worthy of notice are the effect of the ipecacuanha wine in arresting obstinate vomiting; the effect of turpentine enema in overcoming dangerous flatulence; the probable arrest of acute peritonitis by large doses of opium given at the very onset of the disease; the probable radical cure of the hernia by the mass of omental pedicle left adherent in the mouth of the sac.

THE UNQUALIFIED ASSISTANT SYSTEM

AND THE

ILLEGAL SIGNING OF DEATH CERTIFICATES.

As the *Medical Press* has made these subjects its own, by the appointment of a special Commission, and by the publication last year of an exhaustive series of articles; and as, moreover, the matter is of vital importance to the whole profession, we shall now proceed to give our readers the Report of the Committee appointed by the General Medical Council to inquire into the abuses to which we drew attention, and the conclusions founded thereon:—

“One hundred and eighty-eight letters and other communications on the subjects referred to the Committee have been laid before and circulated amongst the members of the Committee by the Chairman. An abstract of the most relevant portions of these documents has been prepared by the Chairman in the form of a ‘Statement’ founded on them, which is appended to this Report.

“The Committee has held five meetings, in the intervals of which the documents above referred to have been passed round to each of the members.

“The Committee has also had the advantage at one of their meetings of the personal attendance of Mr. R. H. S. Carpenter, Honorary Secretary to the Medical Alliance Association, who, at considerable inconvenience to himself, gave evidence by word of mouth, accompanied by documentary proofs, of the prevalence in the metropolis of certain practices to the adoption of which in the provinces the greater part of the writers of the above-named letters bear witness.

“From the evidence collected by the Chairman, and from such other information as we have, we find it clearly established as fact, that the employment of unqualified assistants on duties which ought only to be devolved on persons legally qualified is an abuse which prevails extensively in England and Wales, and that general practice on a very large scale (as in regard of masses of mining and manufacturing population) is often thus carried on in great part by unqualified persons whom members of the profession engage as assistants, and employ as if they were qualified.

“We cannot but believe that, through this abuse of the employment of assistants, much injustice is done to the public, as regards the quality of medical service they are entitled to expect when they apply to a member of the

medical profession, and that, again and again, the profession has very serious discredit brought on it through the incompetence of persons who are thus allowed to practise in its name. We do not think it requisite to dwell on particular facts which are stated to us in illustration of those results of the system. We prefer to insist on the consideration that the system must inevitably tend to produce such results, and that, in relation both to the public and to the profession, it is in principle unjustifiable and dishonest.

"We take as our principle, that no member of the medical profession can rightly employ anyone who is not a member of the profession to act for him as his deputy or substitute in any function which involves an exercise of professional discretion or skill. We are of opinion that any such substitution (wilfully made) of unprofessional for professional service, in practice conducted for gain, is of the nature of a fraud on the public, and ought, therefore, at least in its grosser forms, to be made subject to legal penalty. We are further of opinion that, where such substitution is habitual it can only be regarded as systematic wrong practised by the employer with a view to gain; and that such conduct, whether punishable or not punishable as a public offence, ought to be punishable under the laws and by-laws of the profession, as conduct professionally disgraceful.

"In submitting our opinions as above, we desire particularly to advert to two classes of cases to which they are not meant to apply. First, as regards certain subordinate functions which are ministerial to professional practice, and do not in themselves require an immediate exercise of professional skill or discretion—such functions as habitually and properly fall within the province of the dispenser, or nurse, or dresser, acting under skilled direction, and such as, when the system of apprenticeship was still in force, used often to be more or less devolved upon the apothecary's or surgeon's apprentice—it is not any part of our intention to suggest that an assistant employed only for uses such as those (with or without clerical work) should be required to be a person with legal qualification to practise. Secondly, we do not in any way propose, and, indeed, would most earnestly deprecate, that measures aimed at the abuse of unqualified assistants should be allowed to interfere unnecessarily with the induction of pupils into professional practice, or to hinder such induction within its proper limits. The principle ought, however, in our opinion, to be clearly understood that the pupil is not privileged to do any professional act, except in the presence, and under the immediate guidance, of the legally-qualified practitioner who is teaching him, or, if acting in the absence of his teacher, is only to perform particular subordinate acts which his teacher has expressly directed and limited, and has satisfied himself that the pupil is fully competent to perform.

"We beg leave to draw the attention of the Council to the representations made in our Chairman's statement, and in Dr. William Ogle's remarks which follow it, to the effect that in certain instances unqualified persons, practising on their own account, have as their accomplices members of the profession, who, by acting as 'covers' for them on occasions when certificates of causes of death, and various other professional certificates, have to be given, shield these pretended assistants from inconveniences which the law intends to attach to their position. By doing this, they virtually abet an imposition on the public. Though conduct of that sort is not strictly within the terms of the reference made to us by the Council, we think it sufficiently within the spirit of the reference to require us to express our opinion upon it. We therefore beg to say that, in our judgment, it is misconduct of equal culpability with that which has been more particularly referred to us. As regards the public, and as regards the profession, it is but another form of the same dishonesty, and it seems to us that both forms have to be judged by the same standard of right and wrong. The fundamental intention of the Act which gives legal status and unity to the medical profession of the United Kingdom is 'that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners;' and the man who, as a member of the profession, would frustrate that intention by assisting unqualified persons to pass with the public as qualified, abuses his professional privilege to the detriment of the profession and the public, and in our opinion deserves to be deprived of his professional status.

"Last we should appear to have taken too severe a view of the class of professional offences to which our Report relates, we beg leave to bring under notice of the Council the judgment which the Legislature pronounces on analogous offences

when committed in the profession of the law. The terms in which such offences are dealt with in section 32 of the statute 6th and 7th Victoria, cap. 73, which regulates the practice of attorneys and solicitors, are as follows:—"And be it enacted, that if any attorney or solicitor shall wilfully and knowingly act as agent in any action or suit in any court of law or equity, or matter in bankruptcy, for any person not duly qualified to act as an attorney or solicitor as aforesaid, or permit or suffer his name to be anyways made use of in any such action, suit, or matter, upon the account or for the profit of any unqualified person, or send any process to such unqualified person, or do any act thereby to enable such unqualified person to appear, act, or practise in any respect as an attorney or solicitor in any suit at law or in equity, knowing such person not to be duly qualified as aforesaid, and complaint shall be made thereof in a summary way to any of the said superior courts wherein such attorney or solicitor has been admitted, and proof made thereof upon oath to the satisfaction of the court that such attorney or solicitor hath wilfully and knowingly offended therein as aforesaid, then and in such case every such attorney or solicitor so offending shall and may be struck off the roll, and for ever after disabled from practising as an attorney or solicitor; and in that case, and upon such complaint and proof made as aforesaid, it shall and may be lawful to, and for the said court to commit such unqualified person so acting or practising as aforesaid to the prison of the said court without bail or main-prize, for any term not exceeding one year."

"Before concluding this Report, we think it our duty to state to the Council that, while conducting the inquiry committed to us, we have repeatedly had representations made to us on a point which is of concern to medical education. We find it frequently alleged as an excuse for the improper employment of unqualified assistants, that the subordinate who is without professional title may often be of more convenience to his employer than a legally qualified assistant would be, that not only his inferiority of social rank carries with it some elements of such convenience, but, still more, that many unqualified assistants are abler for certain of the duties which have to be done than many who have a statutory qualification would be. (a) Especially it is stated that the freshly-licensed men are often unfamiliar with midwifery, and with the routine of dispensing and surgery-attendance. It does not in any degree appear to us that the argument to which we refer is valid, or even pertinent, as an excuse for the offence committed. If the practitioner needed his assistant only for uses which might rightly be fulfilled by a person without legal qualification to practise, clearly he would be under no obligation to prefer the professional licentiate, and might at his discretion engage any unlicensed person whom he found better suited to such uses. But unqualified assistants evidently do not exist in their present number with a view only to legitimate uses; and indeed their existence as a sort of profession seems to depend in great part on the fact of their being so largely used for purposes which are not legitimate. It appears to us that in proportion as this is the case, each unqualified assistant is more or less excludng from employment some junior member of the profession; and that, apart from any question of the pecuniary earnings thus diverted from the qualified to the unqualified practitioner, the abuse tends to deprive junior members of the profession of very valuable opportunities of early experience, and thus to aggravate the very evil which is alleged to be the apology for its existence.

"The educational evil, according to the statements which we have received, is, that many freshly-licensed men who offer themselves for employment as qualified assistants are strikingly in want of those particular elements of education which an assistantship under favourable auspices would supply, and which formerly, under the system of apprenticeships, used to be acquired as a matter of course in the early

(a) As regards the comparative efficiency of qualified and unqualified assistants, we should of course expect that the freshly-licensed qualified assistant would in certain respects compare disadvantageously with the person who had made "unqualified assistantship" his profession, and had had some years of experience in it; but we presume that the respects in which the legally-qualified person might fall to show himself the superior would not be those in which professional skill and discretion are required (for in those respects the unqualified assistant could not, except by gross abuse, have acquired the experience on which to found superiority); and it evidently would not be admissible that, for any greater efficiency which he may have as a dispenser or surgery-assistant, he should be deemed a proper substitute for his employer in the responsibilities which are distinctively professional.

stages of the education of all who were destined for general practice. It is not for us, as a Committee on the uses and abuses of unqualified assistantships, to enter on the purely educational questions which may be suggested by the statements which we quote; and we confine ourselves to indicating the educational consequences which in our opinion would result from a rule, strictly enforced, that assistants without statutory qualification must not be employed as deputies in professional practice. If that illegitimate use of the unqualified man were stopped, the legitimate use would in many cases not suffice to make it worth while to retain him, and circumstances would often make it indispensable that a qualified assistant should be appointed in his stead. We think it certain that in this way there would by degrees result a greatly diminished demand for unqualified assistants, and a correspondingly increased demand for assistants of the other class; subject, however, to the important condition, that the legally-qualified assistant would be expected either to have already learnt, or else at least to show himself very ready to acquire, those accomplishments of a subordinate kind in which he is now said to be frequently deficient. We think it probable that, with the circumstances thus changed, the medical student of the future, if intending to follow general practice, would commonly not consider his course of study complete unless he had devoted at least some two or three months to learning, as a pupil, the ordinary routine of an unqualified assistant's duties, as formerly learnt by the apothecary's apprentice; and that, for the purpose in question, general practitioners would very often be asked to receive as pupils, for some such limited time, students who might well desire to utilise those opportunities of learning which in former times attached to the system of apprenticeships.

"In conclusion, we submit to the Council the following recommendations:—

"(a) That the Council ask for legislation to the effect that any registered practitioner, practising for gain, who knowingly and wilfully deposes a person not registered or qualified to be registered under the Medical Act, to professionally treat on his behalf, in any matter requiring professional discretion or skill, any sick or injured person, shall be subject to the same legal liabilities as a person who falsely represents himself to be a legally qualified medical practitioner; but with special proviso that such enactment shall not hinder any duly regulated training of pupils by qualified teachers, nor any legitimate action of nurses, midwives, or dispensers.

"(b) That communications be entered into by the Council with the Registrar-General with the view of procuring such amendments of the Registration Act as will diminish the present frequent evasions of the Act in the certification of causes of death.

"(c) That the Council record on its minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants, and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract, are, if brought before the Council, regarded by the Council as charges of infamous conduct under the Medical Act.

"THOS. K. CHAMBERS, M.D., Chairman."

(To be continued.)

Transactions of Societies.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MARCH 29TH, 1883.

B. WALKER, M.R.C.S.E., President, in the Chair.

INJURIES TO THE EYE.

MR. SNELL exhibited two cases of injury to the eye. The first case was that of a young man, a stonemason by trade, who had been struck with the point of a pickaxe in the left eye. The point entered between the globe and the root of the nose, passing between the internal and superior recti muscles. The injury was followed by complete loss of sight. A point of interest about the case was, that the external rectus was paralysed; it is now, however, recovering. The globe of the eye presented no disfigurement. There is dilatation and want of response on the part of the pupil to the stimulus of light. The second case was that of a boy, who had

received a severe blow on the right eyeball from a large bit of stone. Rupture of the iris was the result. There was temporary loss of sight, but it is now recovering.

ANEURISM OF THE DESCENDING AORTA.

The PRESIDENT (MR. WALKER) showed an interesting specimen of this nature. Its existence had not been suspected during life. The patient, a man, *æt* 27, had been under observation and treatment for over a year for what were thought to have been symptoms of dyspepsia. He had only complained of a pain over the hepatic region and discomfort after food. At times he had complained of pain in his back, but never laid any great stress upon it. He traced his illness back to a supposed strain, which he ascribed to the following accident:—He was about to sit down upon a chair, which he thought was in its usual place. This not being the case, he fell heavily to the ground, and in a doubled-up and constrained position. Since then he has never felt well. The rupture took place into the posterior mediastinum. A clot formed of marked firmness. The lower part of the clot protruded through the oesophageal opening, thus preventing any escape of blood into the abdominal cavity. There was well-marked corrosion of the bodies of the 7th cervical, and the 1st, 2nd, 3rd, 4th, and 5th dorsal vertebrae. The amount of corrosion made the slight character of the pain that had been felt in the back somewhat remarkable. There were some atheromatous patches about the vessels. A week or so before his death he had been able to walk a distance of eight miles.

CANCEROUS TUMOUR OF THE LEFT SCAPULA.

DR. KEELING placed before the meeting a specimen of tumour, growing from the left scapula of a woman, *æt* 51, under his care in the Sheffield Hospital and Dispensary. He had removed the tumour, including the whole of the scapula, except the neck and glenoid cavity. In his operation he had left the shoulder joint intact. The history of the case pointed to a hurt received from a fall as the origin of the mischief. This injury was followed by the rapid growth of the tumour, the growth taking place beneath and along the vertebral border of the scapula; this was lifted up from the walls of the chest. The shape of the tumour was globular. The nature of the tumour was determined by exploratory punctures and placing a bit of it under the microscope. Some spindle-shaped cells, and quantities of small round cells, were found in the specimens examined. The supra and infra spinatus muscles, and the sub-scapularis muscle, were infiltrated deeply with these cells. (Specimens were shown under the microscope.) The bone also seemed affected. If asked for a name, Dr. Keeling thought he would call it osteo-cancerous disease, the character of the cells, infiltration of the muscles, and the rapid growth of the tumour seeming to determine the question of its malignancy.

NEW OPHTHALMIC METHODS.

MR. SNELL drew attention to (1) Snellen's types, and the method and purpose of their use; (2) The use of the actual cautery in the treatment of ulcers of the cornea—he uses a small platinum cautery for the purpose; (3) A new method of treating trichiasis, by means of the galvanic current, applied by means of a suitable needle to the roots of the offending hairs. He remarked that the current should be of the strength necessary to decompose water; he also explained how, when the current has been passed through, the tissues become whitened, and the hairs drop out. He had used it on some fourteen or sixteen cases since Christmas, and with the most satisfactory results.

WEST LONDON CHIRURGICAL SOCIETY.

MONTHLY MEETING, APRIL 6TH.

The President, DR. H. VINEN, in the Chair.

ANKYLOSIS, ESPECIALLY OF THE HIP-JOINT.

MR. C. B. KERTLEY read a paper on ankylosis, especially of the hip-joint, and showed a splint invented by him for use after osteotomy for that affection. He said that although bony ankylosis was generally a very desirable termination of *morbus coxae*, and the best that could be hoped for, unfortunately in the majority of cases it occurred in a bad position. The commonest fault was a compound of adduction and flexion. By it often an apparent and practical shortening of five inches or more was produced when the real shortening was only an inch. The necessity then arose

for a large and unsightly cork boot. The treatment for cases of a certain grade of severity was antiseptic osteotomy, done with the chisel, and, preferably, above the trochanter, through the so-called neck of the femur (really, in most instances, it was a mass of new bone forming the uniting medium). Manifestly, sub-trochanteric osteotomy merely hid one deformity by adding a second. Although supra-trochanteric osteotomy with the chisel was more difficult to a beginner than sub-trochanteric, it became easy enough with a little practice. Strict antiseptic precautions should be used. Usually the first dressing did not require renewal, and had to be kept on less than three weeks. He had had seven cases—five supra, and two sub-trochanteric—each of which had followed an even course, without suppuration or other disturbance, no one remaining in bed more than six weeks, and each then convalescing rapidly. It was now well known that "subcutaneous osteotomy" with a saw was an impossibility in the sense of subcutaneous tenotomy. Anyone who doubted this was referred to a report in the Belgian Academy of Medicine, where it was shown that suppuration, alarming hemorrhage, and severe shock had occurred in a notable proportion of such cases. Referring to the forms of bony ankylosis of the hip, Mr. Keetley said that he passed a rather large osteotome downwards, backwards, and inwards, towards the bone of ankylosis from about an inch outside and below the anterior superior iliac spine, taking care to get it well inside the great trochanter, near enough to the innominatum. The plane of the surface of the chisel must be at right angle to what would be the neck of it, if really a neck existed. The incision for the passage of the chisel is made by a scalpel passed along the groove of a sharp-pointed director, and when the bone is nearly divided, the chisel is removed and force is applied to break the rest. The force used should be partly rotative. The limb is then put into good position once for all, and he applied a splint of his own design. On this splint the sound limb is made to unconsciously exercise the force which keeps the limb operated on in a good position, and the relative apparent lengths of the two limbs can be regulated to a nicety. In conclusion, Mr. Keetley stated that in a case of spastic stiffness he had stretched the great sciatic, and putting in practice an idea of Dr. MacEwen, the anterior crural nerve. The patient, an adult woman, was well satisfied with the result of the operations.

Dr. THUDICHUM remarked that where there was a long neck, he regarded Mr. Adams' operation as excellent; and he suggested that it was of the utmost importance when treating bones to avoid the introduction of infective particles. Where there was a short neck, he thought a circular saw ought to be used.

Mr. LUNN inquired if Mr. Keetley could get movement on a stiff joint? He had a case of fractured clavicle in a man, *æt.* 52, where an attempt to get movement ruptured some muscles and produced a non-pulsating swelling. In consequence of the temperature suddenly increasing, he made an incision an inch below the clavicle. He cleared out a lot of blood, but could not control the sub-clavian artery, and was obliged to amputate the shoulder-joint, an operation which the patient did not long survive.

Dr. ALDERSON asked if the splint exhibited was applicable to fractured femur?

Mr. KEETLEY, in reply, said that he agreed with Dr. Thudichum that there was a future in surgery for the circular saw; he intended to use it as soon as he became the possessor of a surgical engine. At present, however, he was content with the chisel and osteotome. Nothing was more difficult than to give a general answer to Dr. Lunn's question. The amount and character of force and movement justifiable in treating ankylosis could only be decided in each case. Cicatricial adhesions in the neighbourhood of both the joint and the great vessels should induce great caution; so should advanced age. Fortunately, one rarely thought of operating on aged people at all. The splint shown would be quite applicable in the case mentioned by Dr. Alderson.

Dr. F. G. EDWARDS, through the kindness of his colleague, Mr. Coulson, showed a specimen of

DILATATION AND HYPERTROPHY OF THE BLADDER AND URETERS, WITH DISORGANISATION OF THE KIDNEYS, DUE TO PROSTATE ENLARGEMENT.

The patient, William Bachelor, from whom the specimen

was taken, was a postman, *æt.* 67, and was admitted into St. Peter's Hospital on the 26th of December last, on account of frequent desire to micturate, accompanied by great pain of a cutting and burning character in the urethra, which pain was also referred to the anus. For two years previous to admission, he had to have frequent recourse to catheterism, which had become so frequent that on admission he was obliged to pass his catheter every hour and a-half. On rectal examination, the prostate was felt to be much enlarged, as was also the right testicle. The vas deferens was thickened; the *arcus semilis* was well marked; the arteries were hard and tortuous; the urine was somewhat albuminous. On December 27th, to relieve the pain and provide a free exit for the urine, Mr. Coulson performed cystotomy by means of a median incision in the perineum. On passing his finger into the bladder, a portion of the middle lobe of the prostate was found to be pedunculated. This was accordingly seized and excised by means of a long straight probe-pointed bistoury. In the evening, as the urine did not escape freely from the wounds, a canula was passed through the wound into the bladder, and fixed there. On the following day the patient still complained of severe pain in the urethra, and, as the pain increased towards evening, his bladder was washed out and the canula removed. On the 1st of January, the patient being in great pain and little urine having escaped, a catheter was passed, and about six ounces of urine drawn off. As the patient felt easier with it, the canula was retained in the bladder. On the 6th the patient gradually got weaker, sickness and hiccup supervened, and the urine became scanty. Death occurred that evening. In the specimen exhibited the three lobes of the prostate were much enlarged, especially the lateral. From the apex of the middle lobe was a projecting piece of tissue, which, marking the site of the attachment of the portion which was removed, and at the time of the autopsy prevented the escape of three or four ounces of urine which the bladder contained. The kidneys were good examples of the so-called surgical kidneys. The right contained about five ounces of pus, and the left rather less. There was an aneurismal dilation of the arch of the aorta, with extensive atheromatous disease; a fibrous clot occupied both ventricles.

THE RELATION BETWEEN SUBCUTANEOUS NODULES AND CARDIAC VEGETATIONS.

Dr. DREWITT showed a boy, *æt.* 9, who had had rheumatic fever. He had in the knees, elbows, knuckles, and occiput about 36 small slightly movable, painless bodies lying in the fibrous tissue immediately beneath the skin. He had also a loud mitral murmur, which varied at times, and a dilated heart. Probably, therefore, he had vegetation on the mitral valve. The attention of the medical profession in England was first called to these bodies by a paper read before the International Medical Congress by Drs. Barlow and Sainer, on "Subcutaneous Nodules occurring in Children the subjects of Chorea and Rheumatism." They had notes of some twenty-seven cases. They regarded these nodules as indicative of rheumatism, and stated that these bodies were "in their nature probably homogeneous with the vegetation on the cardiac valve." It was worthy of note that in all recorded cases of subcutaneous nodules in children, there was also heart disease, and it appeared as if their locality at least was determined by friction, for they occurred on bony prominences where clothes caused friction, and on the valves of the heart where friction was continuous. The nodules had also been found on the pericardium, where, when inflamed by rheumatism, there was almost as much friction as on the valves. He thought, therefore, from the suggestions he had made, and from the fact that in a case which he had recently shown at another society, where a loud, harsh, mitral murmur almost disappeared when a crop of nodules subsided, that these apparently unimportant bodies have an important bearing on the prognosis of disease of the mitral valve.

We are asked to state that the Duchess of Albany, who will be accompanied by H.R.H. the Duke of Albany, has fixed Tuesday, the 10th of July, for the ceremony of opening the new building for the Chelsea Hospital for Women, the foundation stone of which was laid by the Princess of Wales three years since.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, APRIL 2ND.

JOSEPH WALKER, M.D., President, in the Chair.

SOME interesting specimens of abnormal dentition having been exhibited by Messrs. Hutchinson, Stocken, and Corbett, a paper was read by Mr. J. B. SUTTON, L.R.C.P., on

THE DEVELOPMENT OF THE LOWER MAXILLA.

After showing that great difference of opinion had existed amongst anatomists as to the mode of development of the lower jaw, even so recent an authority as Prof. Humphry considering that it was usually formed from one centre, Mr. Sutton described its growth from six centres, illustrating his description by means of specimens. The first centre to appear was that which formed the greater part of the body of the bone; next came centres for the condyle, coronoid process, and angle, then one in front known as the "mento-meckelian." These united, and then a thin plate of bone appeared on the inner side of the mass thus formed, at right angles to it, but quite distinct. This was the "splenial;" above, it supported the dental follicles, whilst below it was Meckel's cartilage and the inferior dental nerve. A little later the splenial sent down a process from its inner edge which enclosed the nerve, uniting with the outer plate or "dentary," and it also united with this by its outer edge above the nerve. The descending process of the splenial formed the inner wall of the maxilla and a growth upward from it formed the inner wall of the alveoli; after the fourth month all trace of the separate parts was lost, and the bone assumed the condition which it presented at birth. Mr. Sutton next referred to Serre's "Loi de Conjugaison,"—i.e., that foramina in bones are always formed by the apposition of two or more distinct bones, or by two or more distinct centres of ossification—and showed that this afforded *à priori* evidence of the compound origin of the lower jaw, which was fully justified by the results of actual investigation. Lastly, he pointed out the homologies of these centres in the compound jaws of fish, amphibia and reptilia; showing that these parts, which in man united at so early a period that their very existence had been doubted, in some of the lower vertebrates remained separate throughout life, and that thus the evidence afforded by comparative anatomy tended strongly to confirm the compound origin of man's lower jaw.

A short discussion followed, after which

Mr. A. COLEMAN, F.R.C.S., read a paper on

SPONTANEOUS FRACTURE OF THE TEETH.

Cases in which fracture, or splitting of the teeth, occurred without any apparent assignable cause. Mr. Coleman gave the particulars of four such cases which he had met with in the course of his practice; in all of them the pulp was found to have undergone calcification to a considerable extent. It had been suggested that this splitting of the teeth was due to accumulation of gases in the pulp cavity; he (Mr. Coleman) thought it was in some way connected with the calcification of the pulp which was such a constant concomitant, and gave some reasons in support of his hypothesis.

In the discussion which followed all the speakers were of opinion that in these cases of so-called spontaneous fracture of the teeth, the accident was always due to some form of mechanical violence, but that the real cause was overlooked or forgotten, owing to the fact that a considerable time might elapse before any symptoms appeared to call attention to the fracture, and cases were related by Messrs. Charles Tomes, Hutchinson, and Hern, in which there had been complete absence of symptoms for periods varying from three months to nearly two years after such accidental fractures. Mr. Hutchinson also suggested that the calcification of the pulp, which was so generally present, was due to the irritation set up by the fracture, and was, therefore, a result of the accident and not the cause of it.

CLINICAL SOCIETY OF LONDON.

In our report of the last meeting of this Society the remarks made by Mr. James Startin were not quite accurately printed. In speaking of the interest attaching to the history of Dr. Tyson's case and its connection with syphilis, *hereditary*

syphilis should have been mentioned; and in connection with the case quoted by Mr. Startin from his own experience, it should have been stated that "he had seen a patient who had resided in India afflicted with the disease after ten years' residence in England."

France.

[FROM OUR SPECIAL CORRESPONDENT.]

EXTIRPATION OF A LARGE GOITRE.—M. Labbé, of the Lariboisière Hospital, extirpated a voluminous goitre from the neck of a middle-aged woman. The operation was rendered imperative from the condition of the patient, who was being gradually asphyxiated. Knowing that the loss of blood would be fatal to a person already so much reduced, he decided on practising transfusion immediately after the operation. But where was the blood to come from? The woman came alone to the hospital, and had no friends; and who would be willing to sacrifice perhaps his life for that of a stranger! The question was quickly solved: one of the students came forward and bared his arm courageously to the lancet. The tumour was excised, transfusion practised, and the woman is now rapidly recovering. This noble act of the student was highly praised and appreciated by the whole staff of the hospital. The Legion of honour will probably be given to him as a recompense.

THE DEPOPULATION OF FRANCE is seriously occupying the minds of political economists, and in one of the last sittings of the Chamber, a deputy laid on the table a bill which, were it not for its originality, might receive some attention. "Gentlemen," said the honourable deputy, "a great danger threatens the country. It is the stagnation and even the diminution of the population of France, whilst amongst all the other nations there is an increase." The reasons he gave for the decrease were:—1st. Because the people have a dislike to emigrate, the Government having done nothing to encourage it. 2nd. Because the people are not kept enough in the country, and that the taxes are too high. 3rd. Because the Government do not restrain enough prostitution, and do not encourage marriage amongst the poor. 4th. Because the consumption of tobacco and absinthe are attaining enormous proportions, so that the race is becoming weakened and stunted in intelligence and physique. In any case the situation is grave. One of the most distinguished French economists, Beaulieu, said recently:—"If the morals do not change in France, in fifteen or twenty years the population will have an excess of deaths over births." The Bill of the deputy above-mentioned consists of only two articles. The first provides for a decrease in the taxes for every family which has more than four children; while the other proposes a bounty for every child above four where the parent paid no taxes. It is no doubt true that for the workman or the clerk a large family means misery, according to the present régime. Everything is so dear in the large towns that concubinage is preferred to marriage, as the responsibilities are less, since the State provides when required for the children that may be born.

It affords us pleasure to congratulate our esteemed contributor, Dr. S. D. Clippingdale, on the presentation to him of a handsome secrétaire, on the occasion of his resignation of the post of medical officer of the Kensington Dispensary.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 9, 1883.

THE TITLE CLAUSE.

Now that the new Medical Bill has, in its amended form, reached so far in its progress as the House of Commons, expectation of its becoming law during the present Parliamentary Session may be indulged in without extravagant confidence in fortuitous combinations. It will, however, be wise to repress an over-sanguine spirit of belief in its ultimate safe conduct through the stormy ways that front it; but, at the same time, possibilities are sufficiently on its side to make it imperative on us to insist on such further amendment of the measure as shall effect the change without which it will be deprived of an essential element of usefulness. Especially is this true in respect to that portion of the Bill which deals with the question of titles; and above all should it be contended that the original Clause 26 be reinstated as a section of the document.

In a previous article we dwelt on the injustice and mischief that must ensue if, as is at present the case, no provision should be made for conferring on successful candidates at the new final examination some tangible recognition of their having obtained a registrable qualification to practise medicine, surgery, and midwifery. Without, for the moment, referring to the particular action which has resulted in deletion of the title "Licentiate of the Medical Council," we may appropriately dwell on the characteristically emphatic language adopted by Mr. Simon in his supplementary

remarks on the Royal Commissioners' Report, and which especially deals with the question we are considering. Mr. Simon observes:—"My opinion is, that if the Register is to be made as intelligible to the public, and as valuable to the medical profession, as it ought to be, . . . the one common 'title of licence,' and the duly authenticated 'higher titles' ought alone to be registrable; and that all *separate* minor titles ought to be understood as merged in the one *common* minor title which all authorities will have had share in granting." We have in these words the whole principle which is contended for at the present crisis; and the arguments which support the contention, as advanced by Mr. Simon, are practically unanswerable. As he truly puts it, "Persons and public bodies desirous of engaging medical aid and service, and wishing, therefore, to compare together the pretensions of different registered practitioners, are entitled to expect that the Register shall clearly exhibit those distinctions of grade to which importance is attached by persons who understand them, and that it shall refrain from insignificant additions which must mystify and may mislead the public. . . . The new system ought to be represented by a simple Register expressing no distinctions but such as have a substantial meaning. These, under the amended system, would be—(a) that all persons entering the profession will be describable under some *common title of licence*, such as that of 'Registered Medical Practitioner,' or 'Licentiate in Medicine and Surgery;' and (b) that certain of them will possess, in addition to their mere licence, *authenticated higher titles*, which individual authorities will grant, and which the Medical Council, or (on appeal) the Privy Council, will have declared to indicate professional attainments substantially higher than those required for mere licence."

Apart from considerations of local interest, it is difficult to comprehend any valid arguments against so common-sense a view of the matter as Mr. Simon advances; nor even now, and with the whole array of reasons for pursuing another course which have been showered down before us from various of the corporations concerned is it any more easy to perceive excuses for dissent from the original proposals. If the amended Act is to serve the public interests, then it is incumbent on those who are entrusted with the task of framing it to do so with the primary object of ensuring that these interests shall be conserved in the utmost possible degree. And that this can only follow after the removal of existing confusion, as created by the heterogeneous mixture of titles all apparently equally significant of professional attainments, is most clearly and precisely displayed in Mr. Simon's words above quoted. There is, however, in this connection an unfortunate conflict of interests, to which we are chiefly indebted for the weakening influences brought to bear in amending the original Bill with respect to the title clause. On the one hand, and in our opinion of paramount importance, is the inestimable public gain; on the other, the openly-avowed interests of corporations seeking to preserve, at any expense of expediency, all the privileges they have enjoyed in the past; and, so far, it is clearly apparent their combined efforts have been successful.

It may not be out of place here to revert to the manner in which concessions like those already obtained by interested corporations have been gained. Most certainly they have not been granted in response to claims raised by the general body of the profession, and it is by no means improbable, or to a certain extent without justification, that much of the influence brought to bear has been of an individual character. Almost the best privilege enjoyed by medical men is that of intimate association with their patients in relations of a social kind, and which afford them, in their position of trusted advisers, the opportunities of offering responsible suggestions on subjects in which they may be interested, and in the disposal of which those they are attending may have much influence. Situated in positions of this description, it is but reasonable that members of particular corporations should urge the claim of such bodies to especial consideration; and any such exercise of opportunity and power combined is not only legitimate, but, in a way, praiseworthy also. There is the misfortune attending it, however, that the result can only be satisfactory to the interested minority; and we must emphatically urge the extreme necessity at the present time for neglect of all individual representations on the part of those who are entrusted with the safety of the Bill, and that they should pay attention rather to the collective utterances of the profession in all that is of vital interest to the profession.

It is needless to point out that the title clause is a most essential safeguard for the future; that in its absence the worst form of competition among distributors of minor qualifications must ensue; and that its omission will provoke a series of evils in comparison with which previous abuses will compare almost favourably; whilst, against its retention it is possible to urge nothing weightier than the advantages entailed on certain corporations so long as large numbers of young men apply each year for the qualifications they dispense.

As not unworthy evidence of the keen anxiety felt in respect to the title clause of the Bill among a very important and too little regarded portion of the profession—viz., medical students—the result of a discussion on the new Bill held at the Medical Union Society, on Saturday last, deserves attention. Dr. J. G. Glover introduced the subject, and a well-sustained debate ensued among members of the Society, the principal point dwelt on being this question of title. As a final conclusion, the meeting unanimously resolved to forward a petition in favour of the measure to the House of Commons, but making special request for the re-insertion of the title clause in the amended Bill; and we are informed that Mr. Mundella will be asked to receive a deputation of members of the Society, who will urge its views for his consideration.

THE TUBERCLE BACILLI WAR.

KLEBS, of Zürich, has recently taken the field against Koch and his supporters. In an article in the *Archiv für Experimentelle Pathologie und Pharmakologie* (Bd. 16, Hft. 5 & 6), he criticises severely the arguments and

conclusions of the discoverer of the bacillus tuberculosis, and maintains that up to the present, at any rate, Koch has not succeeded in proving his case. According to him, Koch has not proved that his bacilli are organic structures; they may be only crystals. His cultivation experiments are imperfect, inasmuch as in them the cultivation substratum has not been separated from the cultivated organisms, so that it is open to question whether in inoculations the results do not arise from the cultivation liquid, and not from its contained organisms. He (Koch) ought first to have shown that the cultivation substratum was incapable of producing the results actually observed. He agrees with Spina, that other bodies besides the tubercle bacilli are acted on by aniline colouring matter, and in an exactly similar manner.

In a recent article in the *Wiener Med. Zeitung* the subject of Perlsucht, or "grapes" of cattle, and its relation to human tuberculosis, is discussed. The article enumerates the numerous points of difference between the two diseases with a view of showing that perlsucht is not bovine tuberculosis, and that if, as cannot be denied, inoculation by the caseous matter of "grapes" produces tuberculosis in the animal so inoculated, it produces this effect, not by virtue of its tubercular nature, but by virtue of its power as an irritant—that, in fact, it produces inoculation tubercle in precisely the same way as do powdered glass, various bacteria, and nodules of sarcoma. It calls to mind the facts that tuberculosis generally affects the lungs primarily, and that it spreads thence to other organs, or serous membranes, whilst in the case of grapes the process is exactly reversed—it first attacks the serous membranes, and from these makes its way to the lungs. Grapes produce pediculated nodules which may reach the size of a child's head; these nodules generally calcify, and but rarely become caseous; and in none of these particulars does the disease bear any resemblance to tuberculosis. It is conceded that there is a histological identity between the two diseases, but "histological identity does not involve clinical identity. If the one involved the other, then syphilis, lupus, and the inflammation products which surround small foreign bodies when they are injected subcutaneously would all have to be declared identical with grapes and tuberculosis, as they present analogous appearances under the microscope." The writer further mentions the statement of Demme, to the effect that he had discovered tubercle bacilli in three cases of lupus (nodosus and serpiginosus) and makes the following remark thereon:—"Now, according to Koch's teaching, tubercle bacilli are only met with in the products of tubercular diseases, so that, according to this teaching, lupus must now be considered to be skin-tuberculosis, and a contagious disease, a conclusion which will scarcely meet with the approval of unprejudiced clinicians."

Now for the other side. There are not wanting many who have accepted the theories of Koch—in fact, these at present form a majority. Dr. Kredel, assistant in the Medical Klinik of Professor Riegel, of Giessen, delivered an address on March 13th last on Clinical Experiences on Tubercle-bacilli. He found the bacilli in all

the cases of phthisis received into the Klinik, with one exception—viz., the case of a patient who was admitted moribund. In this case, however, they were found post-mortem in the contents of the lung cavities. They were not found, on the other hand, in any case of lung disease of a different nature. The discovery of the bacilli frequently facilitated the diagnosis. Dr. Kredel concluded that the number of bacilli found was of no significance from a prognostic point of view. The presence of bacilli was often noted in the dejecta of phthisical patients suffering from tuberculous intestinal ulcers, but they were absent from all cases in which the intestinal tract was normal.

Dr. Wobly, of St. Petersburg, also reports proofs of the accuracy of the now dominant belief (*Wratsch*, 7/83), of which a notice is given in the *Deutsche Med. Zeitung*, No. 17/83. He made a series of observations on fifty-three cases. Of this number, thirty-five were cases of phthisis, and in every case bacilli were found. The remaining eighteen were cases of various non-phthisical lung affections, and in no case were bacilli found. His conclusions are as follows:—1. The presence of tubercle bacilli in the sputum of patients suffering from pyrexia is a certain proof of destructive processes in the lungs, even when objective changes are not demonstrable. 2. The absence of bacilli does not prove that no tuberculosis is present. 3. Tubercle bacilli have no importance from the point of view of prognosis.

Notes on Current Topics.

Dr. Oliver Wendell Holmes.

THE latest received American medical journals give considerable prominence to reports of a great banquet given to the world-famed poet-physician, Oliver Wendell Holmes, late Professor of Anatomy in Harvard University. Few persons even in this country, and certainly none of any great degree of culture, are unfamiliar with the writings of Professor Holmes, who has given to the world of letters many volumes that will occupy a lasting place in the libraries of the cultivated. The "Breakfast Table" essays of themselves would confer a worthy reputation on their author; but when to these are added, from the same pen, the "Biglow Papers," "Elsie Venner," &c., &c., American medicine may well feel proud in the possession of a genius so remarkable and so versatile. The manner in which our brethren across the water showed their appreciation of the great talents in industry, and labours of their fellow-physician was both happy and graceful; and in the midst of two hundred eminent and representative members of the profession in America the illustrious guest could not fail to be deeply moved at the spontaneous enthusiasm his presence evoked. Dr. Holmes fittingly graced the occasion by reciting a poem specially written for the purpose of expressing the gratitude he felt at the signal honours paid to him; and it cannot but be pleasant to the great world of letters to learn that this production evinces the continued possession by its author of all the fire and genius which characterised his earlier compositions. In the secluded life he has decided to lead henceforth, devoting himself to care-

ful revision of his manifold works, the whole civilised world will anxiously hope that Dr. Holmes will preserve his accustomed vigorous health and strength.

Hospital Expenditure.

At the present time, when hospital finance is engaging so much attention both in and out of the profession, every explanation of the increased difficulty experienced in making both ends meet is worthy of careful consideration in the hands of would-be reformers. In this connection our contemporary the *Philanthropist* cites an example of the way in which hospital charities are abused that is deserving to be repeated. A correspondent of the paper in question asserts that an upper servant of one of the noble speakers at the recent meeting held at Grosvenor House on behalf of St. George's Hospital, some time ago fell ill, and needed such treatment as a hospital only could provide. He was well able to pay as much as would have given him a place in a paying ward, and arrangements were actually made for his admission to one of the institutions which receive paying patients. His master had made the application on behalf of his servant, but for some unexplained reason changed his mind and sent him into St. George's, where, as a governor, he could insure him free treatment. The note then adds, with well-timed truth, that this governor may well be reminded that an institution may be helped by saving its expenditure, especially when such expenditure is upon an object quite unworthy of free treatment.

The late Dr. Richardson, of Dublin.

At the general meeting of the Royal College of Surgeons in Ireland, which took place on Saturday last, May 5th, it was proposed by Professor Macnamara, and seconded by Dr. Edward Stoker, and unanimously resolved:—"That this College has heard with great sorrow of the death of Dr. B. W. Richardson, late Chairman of the Court of Examiners, and now desires to express the unanimous feeling of the Members of Council and Court of Examiners, as well as of the Fellows of the College, viz., That the strict impartiality and fairness which characterised Dr. Richardson as an Examiner were only equalled by the intimate and accurate knowledge he possessed upon the subjects upon which he examined. Such qualities and attainments make his loss deeply felt, and the College deplors this loss, whilst it offers to Mrs. Richardson and her family sympathy and condolence in their sorrow."

Birmingham Hospital Saturday.

THE Hospital Saturday movement was originally established in Birmingham, and, judging from the amount received on the 28th of April last, the day set apart for the 1883 collection, the spirit which animated the originators of this particular charity still stimulates the worthy operatives of this great manufacturing centre. The total sum obtained on the Saturday was £4,230, this being £446 above the returns of 1882. To the subscriptions paid in, however, on Hospital Saturday proper there have to be added those which are not sent in until some little time subsequently, and which in the aggregate reached last year to £1,114, thus raising the total to

£4,888. It is expected that during the present year the amount obtained altogether will reach nearly £5,500, a result which will be of very substantial service in assisting the institutions destined to benefit by it. It cannot but be a very great gratification to Mr. Sampson Gamgee, who was mainly instrumental in bringing the Hospital Saturday movement into active working, to find his unwearying efforts in so good a cause thus progressively successful; and it is still more satisfactory both to him and to all who would wish to see the artisan classes bear a fairer share of the burden of hospital expenditure to note the growth of a feeling among workmen in favour of weekly penny contributions towards the fund. The committee in Birmingham is, in this direction, doing excellent service, and their operations might with advantage be more closely imitated elsewhere.

The Dormant Period of Diphtheria.

In a report conspicuous alike for its careful preparation and for the remarkable thoroughness of the work it describes, presented to the Local Government Board, on the epidemic of diphtheria at Dartford, in Kent, the writer, Mr. John Spear, makes the following concluding statement:—"At the beginning of November, 1881, diphtheria appeared without ascertainable opportunities of external infection in one of a row of houses that had been infected in 1879. Under bad hygienic conditions it spread throughout that household, and the infection was conveyed to Swanscombe School. In Swanscombe village, under like conditions, it extended itself, until April, 1882, with a peculiar interval of latency lasting from the middle of December to the middle of February, re-appearing at the latter date with evidence of its identity. In April it was reconveyed to Galley Hill, disappearing in June, 1882, almost on the spot where it first made its appearance eleven months before." Mr. Spear then makes the following pregnant suggestion, in which experienced physicians will be able to find ample material for profitable reflection. "There can be little doubt that just as this infection was lurking unheeded in the Swanscombe village for the two months above mentioned, so it is now lying dormant in many ill-conditioned spots of this rural district; its future history, whether as harmless matter, or as destructive agent, waiting to be determined by the action of the sanitary authority."

The Elections at the Royal College of Surgeons, Ireland.

ON Tuesday, the 1st inst., the College met to elect Examiners, when, in addition to the members of the outgoing courts who sought re-election, there were nine new candidates whom we named in our last issue. The election resulted in Mr. H. G. Croly, Senior Surgeon to the City of Dublin Hospital, being chosen to fill the seat vacated by the lamented death of Dr. Richardson, all the other members of the Surgical and Midwifery Courts being re-elected with the exception of Mr. Swanzy, who was replaced as Ophthalmic Examiner by Mr. A. H. Benson. In the Preliminary Education Court Dr. Malone was superseded by Dr. Morton, of Nenagh, who had held a place on the court last year, the other members not being re-elected.

On Saturday the College assembled to elect a Member

of the Council in the room of Mr. Croly, who resigned to seek the Examinership. There were four candidates—Mr. Baker, dental surgeon, Mr. Coppinger, of the Mater Misericordiarum Hospital, Mr. William Stoker, of the Ledwich School, and Dr. Abraham Kidd, of Ballymena. Mr. Coppinger retired before the election. The voting was—33 for Mr. Baker, and 46 for Mr. Stoker, who was therefore elected.

Dundrum Criminal Lunatic Asylum.

IN the House of Commons, last week, Mr. W. Corbet asked the Chief Secretary to the Lord Lieutenant of Ireland if he could state the number of deaths occurring annually in the Criminal Lunatic Asylum, Dundrum, from the date of its opening to the present time; the number of post-mortem examinations held annually; whether fees were paid to the former resident medical officer, or whether it was in the time of the present officer only that such fees commenced; and whether it was a fact that the number of deaths and post-mortem examinations latterly had been out of all proportion with those of former years.—Mr. Trevelyan said that the number of deaths in each year could be given, but as the asylum had been open since 1858 they could not be conveniently stated in the answer to a question. He should be very glad to show them to the hon. member, or to send them to him in the shape of a letter. He was informed that in consequence of some of the records of the asylum having been destroyed in a fire some years ago the particulars of the post-mortem examinations could not be given for an earlier period than 1870. The fire occurred before the appointment of the present Governor, who stated, however, that so far as he knew the post-mortems were held by his predecessor. It was true that during the past twenty-eight months the number of deaths had been greater than in any similar period since the asylum had been opened, but the inspector stated that it could not be referred to any particular or exceptional cause.

Mr. Corbet asked if an investigation had been held into a charge of tampering with the faith of a patient.—Mr. Trevelyan said that in the course of 1881 and the beginning of 1882 an inquiry was held into various matters connected with the Dundrum Lunatic Asylum. There had been no alteration in the arrangements with regard to religious observances. He was informed that no particular case had been brought under notice in which a patient who entered as a Roman Catholic was prevented from seeing the Roman Catholic chaplain. There was a case in which a patient was entered on the books as a Protestant, but who, at his own request, was allowed to see the Roman Catholic chaplain. It was not intended to place before Parliament the report of the inquiry referred to.

Notification of Infectious Diseases.

A NUMEROUSLY-ATTENDED meeting of the medical profession of Nottingham was held at the Dispensary on Wednesday, April 18th, to consider the subject of the notification of infectious diseases. After a long debate, the following resolution was put to the meeting:—"That the Town Council be requested to suspend the clauses relating to the compulsory notification of infectious diseases until the subject has been settled in Parliament."

Excision of a Fibroid Uterus.

MINUTE details of a case of this nature are given by Dr. J. M. Gaston, M.D., of San Paulo, Brazil, in the *Medical and Surgical Reporter*, which show that antiseptic surgery has penetrated even to that remote region. The age or personal history of the patient are not given. The tumour occupied the whole of the pelvic cavity, and extended upwards as far as the umbilical line. The operation was performed with rigid antiseptic precautions, and was so far successful that the patient survived the immediate shock, but died five days subsequently from the effects of secondary hæmorrhage and of decomposing blood retained in the pelvic cavity. Several stout silken ligatures were used to secure the pedicle. One slipped, the others held, but at some points showed evidence, on post-mortem examination, of having divided the tissues. The constriction at the cervix was so great that the operator was unable to pass a tube through for the purposes of securing drainage and as a point of resistance against which pressure could have been made by the ligatures placed round the stump to secure the vessels. The pelvic cavity was well cleansed after the operation, and drainage secured by means of a carbolised india-rubber tube, a quarter of an inch in diameter, passed through the lower portion of the wound, about an inch above the pubis. The record of the case is interesting, as bearing on the statistics of this operation. Had a tube been passed through the cervix, as was intended, and had flat ligatures been used, possibly the result might have been different.

Serious Obstruction by Anti-Vaccinators.

THAT an active but unscrupulous minority has the power of stirring up the passions of the ignorant and idle was never more fully exemplified than at Halifax last week, where the anti-vaccination party thought they would make a demonstration against the law. Some goods had been seized in default of payment of fine, and notice of sale had been given by the police authorities; but a few fanatics determined that this should not take place, and by brute force and mob-law succeeded in carrying out their design. How they subsequently fared, and their humble apology, we gather from the *Halifax Guardian*, May 5th. The statement by the Mayor tells its own tale, and affords a salutary lesson for the chief magistrates of other towns. Before the charge sheet of Friday's Court—containing the names of eighteen persons to be prosecuted for non-compliance with the vaccination laws—was taken, the Mayor rose and said that he wished to make a statement with regard to what had occurred on Monday. On that day bills were hung in many shop windows, and a band of music was paraded through the street, both of which were calculated to rouse the passions of the people and to incite to a breach of the peace, and also to prevent the due execution of the law by the officers of that Court. The results showed that those acts were calculated to produce that effect, and did, so far as to interfere with the carrying out of the law. That was a grave state of things to have occurred, and the Watch Committee of the Town Council had to decide what they should do under the circumstances. They had, after careful consideration, come to the decision that they would require from the gentlemen whom they believed

to be responsible for these riotous proceedings a public apology, and also a promise not to give occasion or do anything which would cause a repetition of such proceedings. If they failed to make that apology and to give the promise, the Watch Committee had no option whatever but to take steps which would bring their conduct before a higher tribunal. The Bench acquiesced with the committee entirely, and felt that they could not allow an offence of this kind to pass unnoticed. They were willing to hope that the parties did the acts complained of in ignorance of their probable result, and now regretted doing them, and if the regret was made known in a satisfactory manner no further steps would be taken, but all parties who were brought before the Court must understand that, when an appeal was made to the Court to carry out the law, they (the Bench) had no alternative but to do so; and further than that, he wished to say that, in the opinion of the Court, they did not carry out this law with any feeling that it was an improper law; but even though this were the case with them, it was their duty to uphold the laws, and punish those who broke them. Anti-vaccinators were at liberty to try by fair means to obtain a repeal of the law, but they must observe it as long as it remained the law, and in their agitation to get it repealed, they must see that they did nothing which would be likely to interfere with the due execution of the law.

We are informed that the statement of the Mayor, supported by the Bench, has had the desired effect; the ringleaders of this mob have hastened to publish the following apology:—"We tender to the Watch Committee of the town our sincere regret that we should have in any way contributed to an obstruction of the due course of the law, by opposing, or recommending opposition to, the sale of goods taken under the authority of the law. And we promise that we will not repeat the offence. Signed, &c."

Bacteria in Herpes.

PROFESSOR COLOMIATTI, of Turin, has demonstrated the presence of bacteria, coloured by methyl violet, in the vesicles of *herpes labialis*. So long as the fluid within the vesicles remained clear and transparent, no bacteria could be discovered; but when it became turbid their presence was easily ascertainable. They are not distinguishable from those met with in croupous pneumonia, with or without complication by cerebro-spinal meningitis or endocarditis.

The New Hospital for Women, Liverpool.

WE understand that the committee of the above-named institution have succeeded in acquiring excellent and commodious freehold premises in Shaw Street. The houses are very large, stand in 1,500 square yards of ground, and will furnish space for at least fifty beds. We congratulate the committee and the institution on the wisdom and courage displayed in the acquisition of a site and buildings that will meet the requirements of the charity for probably many years to come. The organisation of the hospital is now complete, and commenced its active existence on the 7th instant by taking over the

work of the Dispensary for Women in Myrtle Street, hitherto carried on by the Ladies' Charity and Lying-in Hospital.

Methods of Colouring Tubercle Bacilli.

TWO of the best methods are those of Koch and Ehrlich. Koch dries a small piece of sputum on a glass square, places it in a weak alkaline methylin blue solution for twenty-four hours, and then washes it over with vesuvine. Ehrlich, after drying the sputum on a glass square, colours it in methyl violet and aniline water. To prepare the aniline water, three parts of aniline oil are added to 100 parts of distilled water, the mixture is then well shaken and filtered. The methyl blue is a concentrated alcoholic solution. Sufficient of the methyl blue solution is added to the aniline water in a watch-glass, to cause opalescence. The prepared sputum (dried) is allowed to remain from a quarter to half-an-hour in the methyl blue and aniline water mixture, after which it is placed in nitric acid, and then water, and is then exposed to Bismark brown, as the final process in the preparation of the specimen. Professor Fränke prefers fuchsine instead of the methyl violet, and then colours with methylin blue.

The Prevention of Conflagrations.

IN consequence of the destruction of so many valuable buildings by fire, the Committee of the Royal College of Physicians of London has deemed it prudent to improve the security of their College, which contains a library and a museum of the greatest importance to the profession, as well as a large number of highly valuable pictures, &c. At the request of the Committee, Messrs. Merryweather and Sons, the well-known fire-engineers of Long Acre, have made a careful survey of the premises and reported their recommendations, after which it was decided that the opinion of Captain E. M. Shaw, C.B., of the Metropolitan Fire Brigade, should be also taken; and in accordance with the suggestions of these experts, we learn that Messrs. Merryweather and Sons have been directed to furnish the College with their system of high pressure fire-extinguishing appliances. Upon each floor a length of light waterproof hose with nozzle attached will be coupled to a hydrant and hung so that any one person can stretch out the tube and cause a powerful extinguishing stream to be ejected upon a fire in less than a minute after its discovery; while a number of buckets will be hung upon each floor ready to be used on the first sign of fire, and in addition there will be supplied handy portable fire pumps, by means of which a person can unaided pump a stream of water high enough to strike the ceiling of each floor with considerable force and thereby command such points as would be inaccessible by water thrown from buckets on account of smoke, heat, light, or other causes. These buckets and hand-pumps will be continually full of water, and available for instant application upon any fire that may be discovered at the moment of its occurrence, so that excessive water damage may be avoided, while the hydrants and hose will be in reserve for the attack of flames which may have been suffered unnoticed to gain a firm hold of a room or two.

These appliances are similar to those which saved the Freemasons' Hall from a calamitous fire on Friday last.

Another Case of Midwifery Mischief.

A MIDWIFE named Goss is now under remand from the Hammer-smith Police Court on a charge of manslaughter, she having been the means of communicating puerperal fever to several patients with fatal effects. The result of the magisterial inquiry remains to be seen, but the case is only one more illustration of the terrible need for speedy legislation in the direction of a Registration Bill for midwives.

THE University College of South Wales and Monmouthshire, towards which the Government has promised £4,000 per annum, is to be opened at Cardiff in October next.

THE following gentlemen have been appointed examiners in State Medicine in the University of Cambridge: Dr. A. W. Barclay, Dr. F. S. B. De Chaumont, Dr. W. H. Corfield, and Dr. Alfred Carpenter.

A BALL in aid of the funds of the Central London Throat and Ear Hospital will be given to-night (Wednesday) at Willis's Rooms, St. James's, under the patronage of the Duchess of Beaufort, the Countess of Dudley, &c.

AT the annual festival held last Friday in aid of King's College Hospital, His Royal Highness the Prince of Wales, in proposing the toast of the evening, dwelt upon the importance of maintaining the hospital, which was in the midst of a dense population of about half a million, and which had been obliged to reduce the amount of its invested capital from £40,000 to but £18,000. Subscriptions and donations were announced in the room to the amount of £4,500, including a donation of £500 from the Goldsmiths.

THE highest annual death-rates in the large towns last week from diseases of the zymotic class were—From whooping-cough, 2.3 in Cardiff and 2.7 in Hull; from measles, 1.1 in Sheffield and 1.2 in Liverpool; from scarlet fever, 1.3 in Wolverhampton and Leeds, and 2.1 in Sheffield; and from "fever," 1.2 in Portsmouth, and 1.4 in Blackburn. The 33 deaths from diphtheria included 20 in London, 8 in Glasgow, 2 in Edinburgh, and 2 in Leeds. Small-pox caused 1 death in London, 3 in Leeds, 3 in Newcastle-upon-Tyne, and 2 in Birmingham.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Leicester 16; Bolton 17; Bristol, Edinburgh, Nottingham, Brighton, Norwich 19; Leeds, Bradford, Sunderland, Wolverhampton 20; London, Newcastle-on-Tyne 21; Cardiff, Preston 22; Portsmouth, Salford 23; Sheffield, Birkenhead, Birmingham, Hull 24; Blackburn 25; Derby, Halifax 26; Plymouth, Liverpool, 27; Huddersfield 29; Manchester 30; Dublin 31; Oldham 32; Glasgow 34.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 30, Madras 32, Paris 30, Geneva 34, Brussels 28, Amsterdam 31, Rotterdam 33, The Hague 23, Copenhagen 21, Stockholm 27, Christiania 16, St. Petersburg 39, Berlin 23, Hamburg 26, Dresden 27, Breslau 28, Munich 31, Vienna 33, Prague 39, Buda-Pesth 31, Trieste 32, Rome 39, Turin 31, Venice 30, Lisbon 32, New York 29, Brooklyn 24, Philadelphia 26, Baltimore 25.

DR. RICHARD TUOHILL REED, LL.D., who died lately at Rome, has bequeathed the bulk of his property, amounting to nearly £50,000, for the encouragement of education in Ireland, and especially in his native county, Kerry. Dr. Reed was educated at Trinity College, Dublin, and formerly held several important appointments at Bombay. He bequeaths in trust a sum of about £10,000, to assist poor boys belonging to Kerry to complete their education; a sum of about £7,000 is bequeathed to Trinity College, Dublin, for the purpose of founding a professorship of penal legislation, including principles of prevention, repression, and reformation; a further sum of about £6,000 is bequeathed to Trinity College for the founding of five exhibitions for students of limited means, from Kerry, who fail in competing for the ordinary sizarships, but who may be deemed to have shown sufficient merit.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE OPENING OF THE MEDICAL SCHOOL, EDINBURGH.—The classes for the summer session opened on the 1st inst. Professor Ewart's class is filled to overflowing, and a large private sale of his syllabus is expected. This syllabus, the professor informed his class, is sold to students at sixpence *under* cost price, hence the necessity for the professor being his own publisher and bookseller. The botany class is well filled. Among the extra-mural lecturers, Dr. Halliday Croom, as extra-mural examiner in the University, has a large class; but Dr. Croom owes his success more to the fact of the excellence of his teaching than to his examinership. Mr. King, in practical chemistry, and Mr. M'Alpine, in botany, also have large classes.

THE REGISTRAR-GENERAL'S RETURNS.—The official returns of deaths in the eight principal towns of Scotland for the last week in April place the average mortality at 27.6 per 1,000 of estimated population. This rate is 3.5 above that for the corresponding week of last year, and 0.1 above that for the previous week of the present year. The lowest mortality was recorded in Aberdeen—viz., 19.5 per 1,000; and the highest in Glasgow—viz., 34.6 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 4.4 per 1,000, or 0.4 below the rate for the previous week. Whooping-cough and measles were the most fatal miasmatic diseases. From acute diseases of the chest, 119 deaths were registered, or 14 less than in the previous week. The mean temperature was 43.0, being 2.1 below that of the week immediately preceding, and 1.9 below that of the corresponding week of 1882.

BARONY BOARD MEDICAL OFFICER.—The Barony Board have, we understand, selected three out of the numerous

applicants for the position of medical officer at the Woodilee Asylum, Lanzie, the gentlemen being Drs. Blain, Dunlop, and Watson. Dr. Blain has been for a considerable time assistant to Dr. Yellowlees, Gartnavue Royal Asylum, and Dr. Dunlop has occupied the position of assistant to Dr. Rutherford at Woodilee. The vacancy is due to the appointment of Dr. Rutherford to the Crichton Institution, Dumfries.

REQUESTS TO SCOTCH INSTITUTIONS.—Miss Catherine Paterson, who died a few days ago, has left the following legacies to charitable institutions:—The Destitute Sick Society, Edinburgh, £300; the Royal Blind Asylum, £500; the Royal Infirmary of Edinburgh, £400; the Royal Edinburgh Hospital for Sick Children, £200; the Edinburgh Royal Maternity and Simpson Memorial Hospital, £200; the National Lifeboat Institution, to build and support a lifeboat to be placed on the coast of Scotland, &c., £1,000. By the death of this lady the following legacies, left by her brother in 1881, also become payable:—To the Royal Infirmary of Edinburgh, £500; to the Destitute Sick Society, Edinburgh, £300; to the Royal Edinburgh Hospital for Sick Children, £300; to the Royal Blind Asylum, Edinburgh, £300; to the Edinburgh School for Blind Children, £300.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.—The following candidates have passed the examination for the L.R.C.P. of this College:—Samuel Cowell Philson, Cheltenham; Thos. Richard Charles Edwards, London; Samuel Camps, Trinidad, West Indies; Charles Richard Owen, Hambrell, Flintshire; Frank Ordfield, London; Edward Tatham, London; Richard Wm. Lloyd, Gibraltar; and Wm. Thomas Partnage, Eddlesborough, Bucks.

FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—At the monthly meeting of the Faculty of Physicians and Surgeons, Glasgow, held on the 7th inst., Mr. A. McPhee, M.B., C.M., was duly admitted, and took his seat as a Fellow of this Faculty.

UNIVERSITY OF GLASGOW.—The following candidates have passed the final professional examination of this University:—Samuel Alexander, Alex. G. Auld, John Beveridge, George Clark, John Clerk, Wm. Colquhoun, Francis H. Colvin, J. B. Cumming, John Cunningham, David Findlay, Alexander Frew (2), Herbert M. Gay, Michael H. Greener, Thomas Howard, Alexander Jack, Arthur G. Keogh, George A. Morris, James W. A. Murdoch, Duncan Macartney, M.A., Wm. M'Cracken, Wm. M'Creadie, David MacDonald, Neil C. M'Donald, Duncan MacGilvray, Hugh M. Mackintosh, David Orr, Alex. B. Paterson, Alex. Peacock, John Ritchie, Richard A. D. Robb, Alex. Robertson, Frank Russell, James Shaw, Alex. J. F. Skottowe, William F. Somerville, M.A., James P. Smith, Joseph Thornley, George B. Todd, R. Bruce Young, M.A., Robert H. Young.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—*Double Qualification.*—The following candidates have passed their final examination, and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh at the recent meetings of the Court:—Thomas Leslie Crooke, Sheffield; James Albert Hunter, Ontario; Matthew Henry Gardiner, Campbelltown; John Small, Fifehire; Percy Howard Day, York; Robert Greenwood Dempster, Liverpool; Walter Frederick Clark, Yorkshire; Hugh Gough Haines, Madras; Karl Wingvist, Sweden; Edwin Alfred Cormac, Edinburgh; Thomas Young, Rowberron; Arthur Ernest Marsack, Olney, Bucks; William Patterson, County Down; Tom Bairston, Halifax; William Henry O'Meara, County Limerick; Robert Williams, Anglesey; John William Dunbar Hooper, Dinapore, India; Edward Albert Warren, Cork; William Henry Percy Fox, Madras; Hunter Urquhart Walker, Madras; Hartwell Woodhouse James, Bangalore; George Hessenauer, Germany; William Henry Harris, Stony Stratford; Richard Macartney, Ceylon; Robert McCall, Edinburgh; Robert Lowry Dickson, County Fermanagh; Arthur Hawkyard, Leeds; Wilton Mills, Whitworth; Thomas Alexander Papillon, Reading; Henry Edward Richardson, Belgium; Bombay; William John Meharry, County Down; Edwin

Gilmore Knill, Ontario, Canada; Henry George Myles, Limerick; Ernest Westbrook, London; Henry Frederic Horne, Bangalore; James Hamilton, Donegal; John O'Brien Mitchelstowndown; John Allen Carr, Bentham; William Allen Fisher, County Cork; Edward Esdale Shiels, St. Louis, U.S.A.; Edward Bridges Townsend, Southsea; William Arthur Dickson, Irishtown, Dublin; Peter Forbes Jardine, Glasgow; Thomas Tension Collins, Tipperary; Thomas Richardson Griffiths, Woolwich; Lambert Houghton, New York; William Kidd, County Down; Alfred Devonald, Pembroke-shire; Cornelius Joseph O'Brien, Cork; William John Cregan, County Down; William Robert Fox, Melbourne; Henry Crombleholme Bradley, Preston.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—During the last sittings of the Examiners the following gentlemen passed their final examination and were admitted L.R.C.S.E.:—David Prain, Fettercairn; James Whitton, Queen's County; John Clancy, County Kerry; Frank Sturges, London; William Guy, Kent; Arthur Herbert Butcher, Ripon. The following gentlemen passed their first professional examination for the Licence in Dental Surgery:—James Maynard Dunlop, Dumfries; James Graham Munro, New York; John Wood, Dalbeattie. And the following gentlemen passed their final examination and were admitted L.D.S.:—William John Mason, Somersetshire; William Thomas Elliott, Diss, Norfolk.

Obituary.

BENJAMIN WILLS RICHARDSON, F.R.C.S.I.

THIS widely-esteemed surgeon died at his residence, 22 Ely Place, Dublin, on the 29th ult., having endured much suffering from cardiac disease. After prolonged study in the Richmond Hospital, he became a Licentiate of the Royal College of Surgeons in 1844, and during the same year, under the Charter then granted, proceeded to the Fellowship. He was soon elected Demonstrator of Anatomy in the Richmond School; but the study of pathological anatomy and practical surgery absorbed his attention, unusual facilities of study then being afforded him in the South Union workhouse hospital, in conjunction with his friend Dr. Robert Mayne, who soon afterwards gained such deserved fame as a consulting physician. In 1856, Dr. Richardson was elected one of the Examiners of his College, and this position he held until his decease, having been for eight years the Senior Member and Recorder of the Court. So admirably were the practical and administrative duties of this office conducted, that it will be scarcely possible to find a fitting successor, and in the vote of condolence to his family unanimously passed at the special meeting of the College on last Saturday, it was truly stated that his knowledge of his subject was only equalled by his impartiality and urbanity. In two other positions which he held for more than a quarter of a century he will be long and affectionately remembered, viz., the Secretaryship of the Surgical Society, in which he followed Dr. Bellingham, and the Surgeoncy of the Adelaide Hospital. His devotion to the honorary functions of the former office induced the members to present him with an address and service of plate during January last year; it was then truly said "that a more thoroughly practical, able, courteous, and efficient secretary" could not have been had. In his hospital he was always a punctual, willing, and reliable colleague, devoting himself especially to improvements of surgical apparatus. Of these, the best known is the dovetail dilator for urethral stricture, which is pictured in Bryant's Surgery, and highly approved of in that and other systematic works. He was always foremost in adopting the practical suggestions of others, and was, for instance, the first surgeon who used the wooden lever for compressing the iliac in hip amputation after its inventor, Mr. Davy. The numerous hospital reports Dr. Richardson submitted to the Surgical Society always excited interest, and in his communication in 1868 to the Medical Council on the course of study, he anticipated many of the points of the new scheme now under trial in the Irish College. Long before the microscope became fashionable he was an ardent and skilled histologist, and he attained considerable skill as an artist and wood engraver. The illustrations in the second and third editions of "Power on the Arteries" were executed by him or under his superintendence. His papers on the Minute Anatomy of the Kidney, and the Modes of Staining Sections, are of great value. Spending his leisure in such occupations, instead of in

the ways more usually followed for attracting public patronage, Dr. Richardson never attained that position as a practitioner which his very remarkable ability and high social standing must have otherwise gained. He was nearly allied to such leading families as the Humes of Humewood, and by his wife (the sister of Sir Leopold McClintock, and of Dr. McClintock, late President R.C.S.), with the noble family of Rathdonnell.

Two of Dr. Richardson's sons became Licentiates of his College; the elder holds a surgeoncy in the Royal Navy; the younger, after a most promising studentship, died a few months since. This trial tended much to hasten the fatal illness of the lamented member of our profession whose career we have striven to briefly sketch.

Novelties.

A NEW INSTRUMENT FOR SUPRA-PUBIC PUNCTURE OF THE BLADDER.

By T. FREDERICK PEARSE, M.D.

THIS consists of a trocar and canula made of a size and shape suitable for tapping the bladder above the pubes, and of a specially constructed silver catheter to fit in the canula. The canula is provided with rings, so that it can be tied in position like a tracheotomy tube. The catheter is made to accurately fit the canula, its point extending about one inch beyond the point of the canula into the bladder. The external portion of the catheter is bent at a right angle for the purpose of fitting on a piece of indiarubber tubing, and is provided with a shoulder to prevent its slipping down the canula into the bladder. The object of the

instrument is to prevent the patient's clothes and bedding from being soiled, as occurs under ordinary circumstances, from the almost constant discharge of urine through the artificial opening, by providing a sort of artificial urethra, which can be opened or closed when desired. By its means the patient is enabled to get up and move about soon after the operation without fear of soiling his linen. The instrument has been made for me by Messrs. Arnold and Sons, of London.

GREEN LEAVES OF THE ERYTHROXYLON COCA.

IN a pamphlet just published on this important drug by Mr. Thomas Christy, F.L.S., the writer gives an interesting account as to the efficacy of the fresh green leaves of this recently discovered therapeutical agent in combating fatigue and drowsiness, in allaying hunger, and in its beneficial effects upon the digestive organs. He also adduces cases in support of the antidotal properties claimed for it in the treatment of victims to the opium habit. Mr. Christy strongly recommends coca to medical men and nurses and all who require to keep awake and on the alert for many hours, as a means of enabling them to go through their duties cheerfully, merely by chewing the leaves. In support of his statements Mr. Christy quotes cases of delirium tremens, phthisis, indigestion, lumbago, and dipsomania, in which coca has been very successfully used, and he offers to send samples of the green leaves gratuitously to those medical men who are desirous of trying the effects of this drug on written application to his address, 155 Fenchurch Street, London.

A SIMPLE INSTRUMENT FOR REMOVAL OF FOREIGN BODIES IN THE EAR.

DR. LOUIS B. COUCH, of New York, has invented an ingenious instrument for removing foreign bodies from the ear, the following account of which has been communicated to the *New York Medical Record*:—"Take a piece of eight-sided brass wire, or round wire with roughened surface, and drill into either end a small hole a quarter of an inch deep. Into one end bronze or solder a small twist drill one thirty-second of an inch in diameter, and into the other a nice sharply cut screw

(such screws may be obtained of any jeweller) of about one twenty-fifth of an inch in diameter. When this is done, you are ready for your smart boy with more beans in his head than brains. Suppose the bean is at the bottom of the auditory canal, enlarged and surrounded by inflamed swollen tissues, a small portion only being visible. Introduce the speculum, and carefully with light pressure drill into the presenting portion of the corn or bean to the depth of about one-quarter of an inch, and clear off all dust, then reverse the instrument and insert the screw, and the bean must come. I have by actual test inserted my sample instrument into a bean, and sustained with it a weight of twenty-five pounds, as shown by scales; a holding power far in excess of that required for the removal of any such bodies. Care, however, should be exercised in first entering the drill, that it does not slip."

"A. & H." MALT EXTRACT.

THE large and increasing consumption of malted articles and extracts by invalids is perhaps one of the most striking developments of modern dietetics. Experience, however, has shown the absolute necessity there is that such products, in order to be effectual for good, should possess the attributes of purity and excellence in the highest degree, and these can never be relied on save when the *imprimatur* of some well-known manufacturing firm lends assurance in this respect. We have, therefore, much satisfaction in reporting favourably on the Malt Extract supplied under the well-known "A. & H." initials of Messrs. Allen & Hanbury, which possesses the important features of reliableness and preservability in all climates, convenience of compounding, and economy in price, while therapeutically it is a most admirable agent.

THE MEDICAL BILL.

THE Bill was brought from the Lords to the Commons and read a first time on Tuesday, May 1st, and is entered for second reading for to-morrow, Thursday, 10th, but whether or not it will be taken on that evening is uncertain.

It is threatened, we understand, with opposition from the Scotch Colleges, and the London Apothecaries' Company will make an effort to regain the seat on the English Medical Board of which Lord Salisbury's amendment in the Lords deprived them. The Irish College of Physicians will renew its effort to obtain a representation on the Irish Medical Board equal to that of the other licensing bodies. The Irish bodies will also try to obtain uniformity of curriculum throughout the Kingdom.

The British and Irish Medical Associations will urge—and, we hope, successfully—that the direct representative, whom the Bill relegates to the obscurity of the Medical Council, shall have a seat on the Medical Board of his own country, and a voice in its medical administration. Lastly, it will, we believe, be moved that the making of the examination and education scheme shall vest in the Medical Council, and not in the various Medical Boards, as is now proposed, such a change in the Bill being obviously expedient if uniformity of system is to be obtained throughout the Kingdom. If each Medical Board is to make its own scheme, and if the Medical Council is to have the task of bringing these schemes to a level, it may reasonably be supposed that endless squabbling will be the result.

We have to record the death of Dr. William Edward Steele, Registrar of the Irish Branch Medical Council, and Director of the Science and Art Department for Ireland, which occurred on Sunday last, from paralysis, with which he was attacked about three months since. Dr. Steele was an M.B. and M.D. of Dublin University of 1837, and a Fellow of the Irish College of Physicians. The office of Director of the Science and Art Department vacated by his death is worth £600 a year, and that of Registrar of the Branch Council, £150 yearly.

Medico-Parliamentary.

HOUSE OF COMMONS.—FRIDAY, MAY 4TH.

THE CONTAGIOUS DISEASES ACTS.

THE Marquess of HARTINGTON, in reply to Lord Randolph Churchill, said that, in consequence of the resolution passed by the House on the 20th April, the Government proposed, as soon as possible, to introduce a short Bill providing for the repeal of the sections of the Acts of 1866 and 1869 relating to periodical or compulsory examination, and including all police action. The proposed legislation would not exclude the consideration by the Government of the whole question with a view either to legislation next year upon the lines recommended by the Royal Commission of 1871, or the Bill of 1872, or possibly to the introduction of clauses into the Bill shortly to be presented to the House of Lords for amending the law relating to the protection of young girls. As, however, it was uncertain when the provisions of the Bill which he had indicated would be passed, it was necessary to consider what action should be taken at once. It appeared that the powers conferred on the Admiralty and the Secretary for War by the Acts of 1866 and 1869 were in the main permissive and not compulsory; and as after the vote of the 20th April there seemed to be no reasonable probability that the House would consent to vote the funds necessary for the administration of the compulsory sections of the Acts, instructions had been given for the withdrawal of the metropolitan police. The visiting surgeons would, however, be retained for the present. Amended estimates providing for the administration of the Acts would be substituted for those now contained in the Army and Navy Estimates. The discussion of the Estimates or the introduction of the Bill probably would afford the most convenient opportunity for entering into further details.

Lord R. CHURCHILL asked whether it was not the fact that, in the recent debate on this subject, the noble Marquess had expressed the opinion that the present Acts were absolutely necessary for the efficiency of the Army; whether that was not also the opinion of the First Lord of the Admiralty as regarded the Navy; and, if so, whether it was now the opinion of the War Office and the Admiralty that the regulation of which the noble Marquess had given notice would provide for the efficiency of the Army and Navy.

The Marquess of HARTINGTON said he did not think he had stated that the Acts were absolutely necessary. All he had said was that he thought they tended to increase the efficiency of the services.

Sir H. D. WOLFF asked when the Government intended to bring in the Bill.

Sir W. HARCOURT.—I should hope immediately after Whitsuntide.

MONDAY, MAY 7TH.

The subject of the Contagious Diseases Acts again occupied considerable time in the House, on the motion of Mr. Paleston, who was anxious to take the sense of members present on the proposal of the Government to repeal the compulsory clauses.

The Marquess of HARTINGTON admitted, in reply, that the Acts had contributed to the efficiency of the Army and Navy, but their administration was fraught with considerable expense to the State; and it did not follow that, because they were popular in particular districts, they should be retained. The House had pronounced against the principle of compulsory examination, and had absolute power to say whether money should be voted to continue the operation of the Acts or not. In these circumstances, the Government had to consider what was the best and most practical course to take, and they had thought it best to suspend the operation of the compulsory provisions with regard to inspection, and bring forward an amended estimate, enabling them to continue the operation of the Acts without those provisions.

Notices to Correspondents.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 28 strings for holding each volume of the *Medical Press and Circular* may now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

THE MOORE FUND.

We are asked to acknowledge, with thanks, the following contributions in response to the appeal (*Medical Press*, April 25th) on behalf of the widow of the late Dr. Moore:—Lawson Tait, Esq., £2 2s.; Robert J. Shaw, Esq., £2 2s.; Bisset Hawkins, Esq., M.D., £2; Reginald Harrison Esq., £1 1s.; Robert Dunstan, Esq., £1 1s.; W. Y. Martin, Esq., 10s.; T. W. Paul, Esq., 5s.

MESSERS. MONK, NEWELL, and BRYON (Rnabon).—The announcement can only appear in our advertisement columns. If so disposed, you must address the publisher.

LAY OPINION OF THE VIVISECTION ABOLITION BILL.—The organ of the Liberty and Property Defence League to hand takes a very common-sense view of this absurd Bill. It says: "The Vivisection Abolition Bill is the product of an inconsiderate and over-strained benevolence, and one would have thought that, especially in this age of anesthetics, the important discoveries of Ferriar, Pasteur, and Koch, would have convinced even the most sensitive that it may be right to inflict pain with due precautions, and without unnecessary cruelty for the sake of inestimable results to humanity and the whole sentient world. It would be interesting to learn in what mind Clause 7 had its origin: 'This Act shall not apply to invertebrate animals.' Why the proud possession of a back-bone should be a condition precedent to kind treatment the Bill sayeth not."

DR. J. KENT SPENDER (Bath) is thanked for his note.

MEMBER B.M.A.—The article you refer to has come under our notice, and has aroused both astonishment and indignation. We shall deal with it, however, in a subsequent issue, after completion of the publication of the report now appearing in our columns. Such course will better serve the cause of legitimate medicine than a hasty reply at present.

A GOOD LINGUIST.—According to the *Philadelphia Reporter*, at the close of Dr. Morrell Mackenzie's lecture at Bellevue, N.Y., one of the students from "Out West" remarked to his neighbour: "That feller talks our language very well for a foreigner."

DR. JACOBSON.—We have consulted the author of the work in question and laid your suggestions before him. You will in all probability hear from him directly in respect to the usefulness of the instrument. Meanwhile, be good enough to communicate with us if necessary.

NEEDLES IN HEART.—CURE OF WARTS.

To the Editor of the *MEDICAL PRESS AND CIRCULAR*.

SIR,—In the "Medical Digest," section 786, 4, may be found several cases somewhat analogous to the one reported of a little girl who died from falling upon a needle she held in her hand. If your correspondent "J. P." will refer to section 70, 3-5, he will find several valuable remedies for warts. Recently salicylic acid has been tried and found most successful.

Yours obediently,
RICHARD NEALE, M.D. Lond.
(Editor of the "Medical Digest").

MR. K. G. SMITH.—You should apply to the Hon. Secretary, from whom all necessary information can be obtained.

MR. TATUM and A. P.—See reply above to Mr K. G. Smith.

ANTI-SPRAY.—The essential element of Listerism is *not* the spray, as Mr. Lister himself has again and again asserted. We can only refer you to the numerous recent utterances on the subject in our own columns and elsewhere.

PRESCRIPTIONS AND THE PURCHASE OF POISONOUS DRUGS.—In France the law requires a chemist to demand the production of a medical prescription before supplying poisonous drugs. Last week a Paris druggist named Vasey was condemned to a week's imprisonment and 2,000fr. damages for repeated sales of morphine to a Madame Junot, amounting in 17 months to 693 grammes, for not demanding the necessary prescription each time his customer presented herself. It appears that at first she presented the medical prescription, but after this she went constantly to the shop without producing any prescription, and she is now in a lunatic asylum. The husband then took proceedings, and has recovered damages above mentioned.

MEETINGS OF THE SOCIETIES.

WEDNESDAY, MAY 9TH.

ROYAL MICROSCOPICAL SOCIETY.—At 8 p.m., Dr. P. M. Braidwood, On Observations on Three Human Contagia.

THURSDAY, MAY 10TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—At 8.30 p.m., Drs. Edmunds and Lawford, On the Immediate Cause of Ophthalmic Neuritis, with cases.—Mr. W. Jennings Milles, On Causes of Recovery from Mild Sympathetic Ophthalmitis.—Mr. Snell, On a Case of Recovery from Sympathetic Ophthalmitis.—Mr. J. E. Adams, On Peculiar Changes at the Yellow Spot.—Mr. Priestley Smith, On a New Self-registering Perimeter.—Mr. Conper, On a New Refraction Ophthalmoscope.—Mr. J. E. Adams, On an Ophthalmoscope for Artists.—Dr. Bralley: (1) On a Case of Pseudo-gloma; (2) On a Second Case of Asthenopia treated by a Vertical Prism; (3) On a Case of Muscular Asthenopia in a Child.—Living Specimens at 8 o'clock.

FRIDAY, MAY 11TH.

CENTRAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. Dalby, On Examples of the Two Classes of Cases in which Cerebral Abscess, Meningitis, or Pyemia Originate in Disease of the Ear.—Mr. Nettleship and Mr. Higgins, On a Case of Morphaea in the Region of the Fifth Nerve, with Paralysis of the Intraocular Branches of the Third. Dr. B. Lee, On a Case of Nystagmus Infantilis.—Mr. A. E. Barker: (1) On a Case of Goitre producing great difficulty of Breathing on Excretion; Excision; Recovery and complete relief. (2) On a Case of Sebaceous or Dermoid Cyst of the Tongue; Removal by Submental Incision; Cure.—Mr. J. H. Morgan will exhibit a Case of Congenital Deficiency of Femur; Dr. Stephen Mackenzie, Case of Myxodema in a Male; and Mr. Bernard Roth, Case of Lateral Curvature of Spine (now under treatment).

ACADEMY OF MEDICINE IN IRELAND (Surgical Section).—Living Specimens: The President, 1. A Case of Necrosis of Cavity in the head of Tibia; 2. A Case of Necrosis in lower extremity of Tibia; both cases operated upon.—Mr. Croly, 1. Recent Amputation at the Shoulder-Joint; 2. Radical Cure of Inguinal Hernia by Dissection; 3. Syme's Amputation at Ankle-Joint.—Dr. Baxter, Excision of the Elbow.—Mr. Thomson, Primary Excision of Knee.—Mr. Wheeler, Amputation at Shoulder-Joint.—Dr. Mapother, Hemorrhagic Ulcer of Scalp.—Mr. Stokes, Radical Cure of Inguinal Hernia by Dissection. Specimens exhibited by card: The President, Pieces of Necrosed Bone removed by Operation.—Mr. Stokes, 1. Cast of Stump after Supra-Condyloid Amputation of the Thigh; 2. Osseous Structures of Lamb removed; 3. Head of Humerus removed in Excision of Shoulder-Joint.—Dr. McCullagh, 1. Fibroid Tumour removed from Interior of Superior Maxilla; 2. Section of same.—Dr. Baxter, 1. Parts removed after Excision of the Elbow; 2. Parts removed after Excision of the Knee; 3. Venial Calculus.—Mr. Croly, Foot Amputated for badly-united Fracture.—Mr. Thomson, 1. Subclavian Aneurism, and Ligature of the Arteria innominata; 2. Head of Humerus removed in Excision of Shoulder-Joint; 3. Parts removed for Compound Refracture of the Patella.—Mr. Wheeler, 1. Portions of Femur and Tibia after Excision of Knee; 2. Casts of rare Deformity of Hands and Feet in Child; 3. Disease of Foot after Syme's Amputation. Papers: The President, On Excision of the Hip.—Dr. J. Stack, Replantation and Transplantation of Teeth.

SATURDAY, MAY 12TH.

ROYAL INSTITUTION.—At 3 p.m., Mr. A. Geikie, On Geographical Evolution.

TUESDAY, MAY 15TH.

ROYAL INSTITUTION.—At 3 p.m., Prof. MacKendrick, Physiological Discovery.

Vacancies.

Coventry and Warwickshire Hospital.—House Surgeon. Salary, £100, with board and lodging. Applications to the Secretary on or before May 16th.

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary to commence at £85, with board and residence. Must be conversant with the Welsh language. Applications to be sent to the Secretary before May 26th.

Dunmow Rural Sanitary Authority.—Medical Officer of Health for the whole District. Salary, £50. Applications to be sent to the Clerk on or before May 21st.

Hospital for Diseases of the Throat, Golden Square.—Resident Medical Officer. Salary to commence at £50, with board and lodgng. Applications to the Chairman of the Committee on or before May 21st.

Royal Berks Hospital, Reading.—Assistant to the House Surgeon. Board and lodging, but no salary. Applications to be forwarded to the Secretary before May 8th.

Appointments.

GREER, T., M.D. Q.U.I., Surgeon to H.M.'s Prison at Inverary, ARG shire.

SMITH, E. Noble, F.R.C.S.E., Orthopaedic Surgeon to the British Home for Incurables.

Births.

BARR.—May 2nd, at 1 St. Domingo Grove, Liverpool, the wife of James Barr, M.D., of a son.

BOLTON.—April 28th, at Kustendjie, Roumania, the wife of A. Irish Bolton, M.B., A.B., T.C.D., of a daughter.

CAHILL.—April 26th, the wife of Dr. Cahill, Dame Street, Dublin, of a daughter.

LANGDON.—April 26th, at Gibraltar, the wife of Surgeon J. S. Langdon, A.M.D., of a daughter.

STAMPER.—May 3rd, at Pembroke Dock, the wife of J. Fenton Stamper, M.D., of a daughter.

Deaths.

FURNEY.—April 7th, accidentally drowned, at New York, Simon Kenny Furney, L.R.C.S.I.

HALLOWES.—May 2nd, at Carlisle, George Blackwood, son of the late P. B. Hallowes, F.R.C.S.E., of Canterbury, aged 42.

HARTFORD.—May 3rd, at Middleton, co. Cork, George Hartford, M.D., aged 82.

MASSBY.—April 23rd, William Massey, L.R.C.P.Ed., M.R.C.S., of Castle Donington and Melbourne, aged 52.

RENTON.—May 3rd, at 15 Bothersey Place, Edinburgh, A. A. Renton, M.D., F.R.C.P.E., late Surgeon-Major Madras Army.

ROPER.—May 3rd, at Richmond, Surrey, Giles Simonds Roper, M.R.C.S., late of the City Road, London, aged 67.

STEELE.—May 6th, at Wilton, Bray, co. Wicklow, William Edward Steele, M.D., F.R.C.Q.P.L., Director of the Science and Art Museum, Dublin, and Medical Registrar for Ireland, aged 64.

ON

HYSTERICAL CONTRACTION OF TRAUMATIC ORIGIN. (a)

By J. M. CHARCOT, M.D.,

Professor to the Faculty of Medicine, Paris; Physician to the Salpêtrière Hospital; Fellow of the Clinical Society of London, &c.

GENTLEMEN,—In to-day's lecture, which inaugurates the course of the year, I desire to call your attention to two cases which have recently come under our notice, and which many of you have already had occasion to examine at the Salpêtrière Hospital. These two cases appear to me to be well worthy of your attention; they possess in common striking analogies, so much so that they appear to originate in like manner, and merit, in all respects, to be considered together. Each offers, indeed, an example of an anomalous hysteria, in respect of the absence of convulsive crises. They have further in common another peculiar feature, viz., the existence of a spasmodic contraction limited to one of the hands, and developed, according to all appearance, by some exterior excitation. I would add that while one of the cases is that of a female, in whom as a rule hysteria usually exists, the other is that of a male, a circumstance which undoubtedly ought to rivet your attention and interest. There are two special points to which I shall give prominence—1st. Hysteria wanting in a symptom almost classic, viz., the convulsive attack; and 2nd. Permanent spasmodic contraction developed in consequence of a traumatic origin; and between these two points I shall endeavour to establish a parallelism. With that exordium we consider the details of the first case. The patient, as you notice, is a young girl of sixteen or thereby, and of a delicate appearance. Her physiognomy is sufficiently calm, and presents no peculiar feature. We do not find her gaudily attired as these subjects usually are; she does not appear to belong to the usual blustering class; but, it may be remarked in passing, these placid hysterical patients are not always the most easily cured. Certain

circumstances in the early history of the patient merit attention. Patient is an orphan, and at eleven years of age, was received, in consequence of the death of her mother from pulmonary phthisis, into one of the religious establishments. Yet another circumstance more striking, her father died in the lunatic asylum of Orleans, where he lived three years. The disease which necessitated his residence in this asylum seems to have been general progressive paralysis, if one may so judge from the fact that he had several convulsive attacks, after which he became paralysed. I would add that one of her brothers, aged thirteen, received into an almshouse, is almost an idiot. These circumstances deserve prominence, inasmuch as they indicate the inheritance of a nervous tendency, an element of the first order in the etiology of hysteria. It exists in this connection, according to Briquet, in thirty per cent. of cases; sometimes, following the nomenclature proposed by M. Prosper Lucas, in the connection of *homonymous heredity* or of *similitude*, one hysteric begetting another; sometimes in that of *heredity of transformation*, the parents being affected with some other nervous disease, such as insanity, epilepsy, &c.

In the personal antecedents of our patient we find scarcely any illness of note, with the exception of a somewhat severe attack of bronchitis of three months' duration. Phenomena of hysteric convulsion wanting both in the past and present. Our patient is ignorant of the hysteric *botus*, of spasms, and convulsions. So far as concerns her normal condition, the information obtained from the lady-superior of the convent in which she lived is not very explicit. "She has an extreme desire of liberty; her conversations and her dispositions are not good." What is there behind this monkish reticence? As yet we do not, but by-and-by we shall doubtless be able to comprehend. Meanwhile, we are in presence of a capital fact, the malformation of the left hand, which as you see, represents a veritable club-hand, which I shall call hysteric. I will at once explain to you under what circumstances this malformation has become developed; indeed, I need but signalise one point; this malformation has persisted during one year. Since that time it has been permanent, without cessation or truce, except during a

(a) Translated from *Le Progrès Médical*

Period of two months, when it somewhat diminished under the influence of treatment.

The wrist is free, as is also the other articulations of the superior extremity. The malformation, then, is limited to the hand. The first phalanges are flexed on the metacarpal bones, while the other phalanges present only a slight degree of flexion. The fingers thus flexed are pressed together, and, as a whole, form a sort of cone, whose summit corresponds to the extremities of the last phalanges. The thumb, adducted, is forcibly applied against the index finger. It is easy to convince one's self that muscular rigidity is the sole cause of this malformation, and that the articulations and ligaments are unaffected. Attempts at reduction sufficiently demonstrate this. Chloroformisation would have afforded instant proof; but we dreaded a perturbation which might have prevented the study *de visu* of this condition. We find here besides the characters of spasmodic contraction, that the flexors are specially affected and cause the deviation, the extensors are also affected, for it is as difficult to exaggerate the flexion as it is to produce extension. That simultaneous antagonistic action is one of the characters of spasmodic contraction on which I shall revert. The deformed hand is colder than the other, and presents a sufficiently distinct bluish colour, denoting an affection of the vaso-motor system. There exists an atrophy or rather a slight emaciation, not only of the hand, but likewise of the other segments of the member. The forearm is less by a centimetre in circumference than its fellow. This does not arise from actual atrophy, but from emaciation due to prolonged repose. We find besides a diminution of special and general sensibility on the entire half of the body, corresponding to that of the deformed hand. We have here to deal with, observe, a permanent contraction in the true acceptance of the term; we find it night and morning; it persists during sleep, a fact of which one can easily be convinced seeing that this side being anæsthetic, examination can be made without rousing the patient. The idea of deception cannot, therefore, be entertained.

What are the muscles concerned in this abnormal position? It is the *interossei* particularly, for as demonstrated by Duchenne (of Boulogne) these muscles are the flexors of the first phalanges; and besides, the palmar *interossei* cause the fingers to approximate towards the middle line, and thus press one against another. But the *interossei* are not alone affected, for the two last phalanges are also flexed, and that position is due to the action of the deep and superficial flexors. We therefore recognise not only the action of the ulnar nerve which supplies the *interossei*, but also of the median, which supplies the flexors. Further, the action of the median is disclosed in the position of the thumb. Observe besides, that the thumb is not only in *adduction*, but at the same time, in *opposition*, it is carried inwards; but the nail is directed forwards, and not directly outwards as in simple adduction. The adduction of the thumb is caused by the interosseous adductor of the first space, which is supplied by the ulnar; the other movement is caused by the *opponens pollicis*, which is supplied by the median. Hitherto we have confined ourselves to simple statements relatively to the mechanism of the deformity of the hand. We now produce, by means of *localised electrification*, after the method of Duchenne (of Boulogne), the following conditions, which present for examination. In normal subjects this means of experimenting is somewhat difficult, owing to the pain caused by faradisation. This difficulty, however, does not exist in anæsthetic hysterical subjects, who can thus be operated on without experiencing any pain.

I now present for your examination, B. L., an epileptic-hysterical patient, with left hemianæsthesia. We have marked a certain point within the tendon of the *flexor carpi ulnaris*; that is, the point of faradisation of the internal ulnar nerve of the wrist (deep palmar branch of the ulnar nerve). You will observe that faradisation causes a *partial ulnar flexion*, which recalls the case of

our patient in whom the *interossei* and adductors of the thumb are alone in action. If, on the contrary, we excite the ulnar nerve in the groove between the internal condyle and the olecranon, we determine a complete ulnar flexion, with flexion of the third and fourth fingers, the latter effect being due to excitation of the ulnar portion of the *flexor profundus digitorum*. These conditions are still more easily studied in individuals in the hypnotic state. We are able thus to profit by the *neuro-muscular hyper-excitability* which then exists, and excite the same conditions by irritation of the nerve by any hard object, without faradisation. The advantage of this experimenting consists in the fact that these attitudes are permanent, as you see in that patient on whom you see us produce by simple touch of the ulnar at the level of the wrist (annular ligament), the interosseous flexion; or, if by so acting in the *humeral groove* the complete ulnar flexion. Having excited the *interosseous flexion*, you see us produce exactly the malformation of our first patient by exciting the *opponens* muscle. I would have you observe that in this hyper-excitabile subject the contraction of the hand presents all the features of a spasmodic contraction, the position is fixed, the flexors and extensors are in action, there is evidently a spinal cause—but to that subject we will return in the sequel.

Returning to our patient, we have demonstrated that we have to deal with a spasmodic contraction; but it remains for us to show that it merits the term hysterical, and that a favourable prognosis is thus justifiable—in other words, that, notwithstanding the long duration and obstinacy of the malady, it will prove amenable to suitable treatment. That diagnosis is based—1st. On the fact that the *intensity* of the contraction is greater than in that usually associated with organic lesion; and 2nd, on its absolute permanency both day and night—in cases of hemiplegia the contraction diminishes usually to some extent during sleep; 3rd, the circumstances under which the malformation originated is a subject of much importance. Two years ago, on the 2nd of November, 1881, a trifling wound is sustained, by the breaking of a pane of glass, at the level of the second metacarpal bone, which cicatrised in about four or five days. It was this trifling wound which determined the contraction; and this is a feature of some importance. At first there was an absence of pain. The deformity persists long after the wound is healed. Doubtless in subjects with organic lesions (descending cerebral or spinal sclerosis) the same would produce itself in consequence of a wound; but in the latter case, generally, the onset of the contraction is not abrupt, there is not the same disproportion between the trifling nature of the wound and the intensity of the contraction, which has not either the same persistence after the cure of the peripheral irritation. This disposition to contraction in hysterical cases—a special *diathesis*, which is occasioned by an ordinary wound—is in some subjects very remarkable. For a long time I have noticed that in the case of certain hysterical patients in consequence of a sudden movement—in throwing a stone, for example—the arm remained in a state of contraction. We are able to produce the same phenomenon on the patient M—, whom I show to you. You see me in suddenly manipulating the foot determine a kind of *talipes equinus*, which does not give way until after prolonged *massage*. Note that that contraction takes place during waking, and that it has the same persistence as that which we produced during the hypnotic sleep. To return to our case. You observe that the train of considerations permits us to assume that the affection is hysterical. But that presumption, already so strong, changes into certitude when we study more closely the characters which more and more firmly establish the substratum.

Notwithstanding the absence of convulsions, our patient presents a sufficient number of nervous troubles which constitute the hysterical state. There exists left *ovarian irritation*, left *hemianalgesia*, not alone in the hand, but in the two extremities, the trunk, and the head. The patient is not affected by faradisation of the skin. There is besides a *sensorial hemianæsthesia*. The organs of sense

are affected in a corresponding manner to the integuments, a point on which I had already occasion to revert, and which in this particular case has been specially signalised in what relates to the hearing by M. Walton. The sense of smell and taste are equally affected. It is the same with vision, for the field of vision is narrowed for luminous perception, and perception of colours, with transposition of the red circle exteriorly. There is, besides, a diminution of acuteness of vision to a sixth of the normal degree. We, therefore, find in our patient all the characters of hysteric *hemianæsthesia* with ovarian irritation. These sensitive perversions could be otherwise occasioned only by active cerebral lesions situated in the sensitive tract, or by alcoholism, or by lead poisoning; but as there are no indications of these causes in our patient, we are bound to conclude that all the pathological phenomena are purely of a hysterical origin, and thus symptoms otherwise difficult to be explained are at once easily comprehended.

(To be continued.)

ON THE DIFFICULTY OF DIAGNOSING TRUE SYPHILITIC DISEASE IN WOMEN, AND THE NATURE OF ITS CONTAGION. (a)

By C. H. F. ROUTH, M.D. Lond.,

Follow of University College, London.

(Continued from page 399.)

III. I now proceed to my second point. The nature of the contagion.

I quote here again from Guyot the opinion of the great syphilograph Ricord. That gentleman has proved that one drop of pus taken from a syphilitic sore and dissolved in one glass of water forms a solution, a single drop of which would suffice to inoculate the disease in a healthy person. It has been conveyed by an insufficiently washed speculum, or a vaginal cannula, so much so that Dr. Giering, of Copenhagen, attributes the increase of syphilis in that town to the obligation lately enforced there of examining the women twice a week.

Assuming, however, this excessive contagion of true syphilis, there are two ways in which it may be conveyed to another person: 1st, by her secretions; 2nd, by mediate contagion, and this especially by syphilitised women.

1st. By this excessive contagion of syphilis we can, in a measure, understand that a woman should disease a man by her secretions, although no sore of any kind can be found in the sexual organs. This is the definite opinion of most observers, notably Mr. Henry Lee, Dr. Drysdale, Dr. Graves, of Dublin, and all French authors. Mr. Lee goes so far as to say that more than half the cases of syphilis which occur in men are due to contagion from women in such a condition. Dr. Graves proved it incontestably by inoculation from a woman who had been cured of all primary symptoms for over three months. Moreover, inoculation has verified the asseveration over and over again, and now that secondary symptoms are admitted to be contagious (a fact so long denied by Ricord) this cannot be said to be unlikely. But Mr. Fournier extends this contagion to a period of three or four years, during the whole time of which the patient should be medically treated before a marriage could be safely concluded. I suppose also that it will be admitted that the same woman may at different periods (especially immediately before and after the catamenia, and whenever there is any admixture of blood in her secretions) convey not only more certainly, but more severely syphilis, the blood of truly syphilitic persons being particularly infectious.

2nd. *Mediate Contagion.*—During the late inquiry before the Contagious Diseases Act Commission another mode of contagion was very warmly insisted upon by its

opponents, and almost invariably admitted by its supporters, *i.e.*, what is called mediate contagion. It has been stated in evidence that some of these unfortunate women have connection with as many as twenty-five men in twenty-four hours. The same is asserted as the case in France by M. Guyot, from six, ten, and twenty-five times, and I have heard of a well authenticated case where, during the rejoicings in New York on the Anniversary of the Independence of the United States, a wretched creature was desecrated twenty-six times in twenty-four hours. Suppose one man only of these were diseased, and, regarding Ricord's experiment, how many men would be capable of being contaminated by that one woman?

3rd. But this infection becomes infinitely more probable if the woman herself be syphilitised. It is admitted, and, I believe, on all hands, that a woman once that she has had a hard indurated sore, becomes in measure syphilitised, *i.e.*, innocuous to a very great degree, if not altogether, to the recurrence of true syphilitic disease, if once cured of it. This last opinion is given very unequivocally and decidedly by Dr. Drysdale. "When once a woman has had syphilis, she has had it for her life." In this respect it resembles typhoid, whooping cough, small-pox, which very rarely can be caught twice. This is also Mr. Lee's opinion. Ricord himself asserts that while gonorrhœa and soft chancre can be reproduced indefinitely, true syphilis can never be doubled, *i.e.*, occur twice (Guyot, 283). I know this opinion has been controverted by other French authors, notably Brunet and Fait. The latter instances a case where a girl contracted syphilis ten times in two years: Several others five or six times in the same period. But, after all, this occurrence, which at most is exceptional, is only in keeping with the occasional recurrence of small-pox, measles, scarlet fever, &c. Without a doubt syphilitisation must be admitted as true doctrine. Doubtless, also, we must allow that rarely ever, possibly never, do prostitutes carry on their trade without contracting syphilis sooner or later, and, if so, there must come a time when a thoroughly syphilitised woman becomes one of the most prolific contaminators of men through mediate contagion, although she may escape being again diseased herself. The older the prostitute, the more likely is she to be syphilitised; and thus the result of our own, as well as foreign, Contagious Diseases Acts, which are supposed to reclaim and discourage juvenile prostitution, is the laying down of a foundation for a great increase of the disease hereafter. The very disease, caught by a young girl before she becomes hardened, frightens her, and so far, when backed by kindness, is an incentive to her to give up the life, and return to better ways and to her friends. The fear, also, of a persecuting police has a similar tendency, although from a different motive. It is this fear in France which leads to the disappearance of young prostitutes, for there little care is taken to reform the girls. A large number give up the life after from three to five years. They have sown their wild oats, as many a young man has done also, and return, if allowed, to virtuous habits. The old women, however, either cannot do so, or become hardened, and thus it is they become foci of disease. This was shown by a return of the number of women engaged in prostitution under the Acts in England, with their respective ages. In England, before the Acts, women who became prostitutes scarcely remained as such longer than four years. Eighty-six were under 26 years old. Only about 3 to 8 per cent. continued prostitutes after the age of 31 years. Now, 46 per cent. are over 26 years old, and women above 31 are about five times as numerous, representing 20.6 per cent. The same thing has been observed in France. Few girls are found to carry on the trade beyond four or five years. This becomes obvious by the following statement, made by Guyot, that from October, 1878, to January 1, 1880, 3,445 women were arrested for trying to escape prostitution, and of these 2,305 were minors, and only 1,138 majors. The

(a) Read before the Medical Society of London.

following table of minors and majors remaining inscribed in houses of ill-fame in Paris points to the same conclusions:—

1880 ...	7312	3344	354	1935	1159	3582

This diminution is, however, by no means confined to the minors. If you refer to Table II. and III., in one of which the number of arrests, radiations, re-registrations, and replacements is given, and in the other, in which the percentage to population is given, you will find the numbers of registered women is annually diminishing, and is only kept up by the persecutions of the police. Lecour, indeed, boasted that he arrested 10,000 annually; and certainly, were it not that the police know by face and person, and invariably hunt out these miserable creatures as so many criminals when they seek other employment, the number would be diminishing much more. The system of licensing in thus frightening away the younger women, and retaining the older, a large number of whom are syphilitised, has the effect of defeating the object of examinations, and promoting syphilitic disease among those who have intercourse with the latter.

4th. Again, the contagion of syphilis and its virulence is intensified by the licensing system, and especially by the establishment or toleration of brothels (a), the habits of the women who live in them, and the sanitary condition of the dwellings being generally bad. I might, indeed, quote here the graphic description of Mr. Sheldon Amos on the deplorable condition of the inmates of a brothel, but I prefer to give that of an opponent—Dr.

(a) In many houses, particularly in Brussels, the women are seldom, if ever, allowed to go out. By way of consolation, they are piled with drink. They have absolutely no power to reject the embraces of any man, be he ever so disgusting and repulsive. They are obliged to submit to every degradation to which they may be forced.

Mireur. He says such a woman "is the modern slave, who, having made the sacrifice of her personality, is become the plaything of her mistress and the property of the public." He adds: "Death strikes nearly all these women in the flower of their age. The hospital is almost always their fatal goal. The debauch which made them live yesterday makes them die to-day." Our own Acts tell the same tale. Captain Harris's last report states that, although from 1870-1880 the number of registered women has diminished, the annual percentage ratio of disease has increased, and that since 1875 it has been regular and continuous (148 to 176 per cent.), or stated deliberately, that on an average every woman was sent to hospital nearly twice in each year. More accurately, the total number of cases of disease was 3,316, representing 1,849 individual women out of the total number of 3,268 on the register.

(To be continued.)

A SIMPLE SPLINT FOR THE ELBOW.

By NORMAN PORRITT, L.R.C.P.Lond., M.R.C.S.Eng., Fothergillian Gold Medalist, Medical Society of London; late House-Surgeon, Infirmary, Huddersfield; and Senior Assistant House-Surgeon, General Infirmary, Leeds.

CASES of injury and disease in and about joints are among the most important and occasionally the most difficult and trying cases the surgeon has to deal with, and there is a class of injuries to the elbow-joint whose characteristic is rapid and great swelling around the joint. Unless such cases are seen almost immediately after the accident, it will be difficult, and often impossible, to determine the exact nature of the injury, for, in addition to the swelling, tenderness on manipulation will have supervened. When there is a dislocation of the elbow, or a complete fracture across the lower end of the humerus, the diagnosis is not, as a rule, long delayed; but my remarks refer to cases of partial fracture about the elbow without displacement, and to other cases characterised by inordinate swelling, whose nature is at best obscure.

For such cases the splint here figured was devised. It consists of a flat bar of iron bent at one end to rest easily on the shoulder and back, and modified at the other to support the hand. The end of the shoulder-

piece rests over the base of the scapula, on a level with the upper border of the axilla, and is secured by a bandage passed from it over the opposite shoulder, over the front of the chest, through the axilla of the affected side, and thence horizontally once round the body, between the end of the splint and the first turn of the roller over the shoulder. It is then tied. Thus the end of the splint is immovably fixed, and cannot slide either upwards or outwards.

The elbow being bent at a right angle, the hand is secured to the other end of the splint, and rests easily and comfortably on the support provided for it.

Applied thus, the shaft of the splint extending from the anterior axillary fold to the wrist forms the base of

a triangle whose sides are respectively the arm and forearm, the apex being at the elbow. There is, therefore, considerable space between the elbow and the shaft of the splint. The splint moves on the fixed posterior extremity as on a pivot, and it will be found that, although the splint and limb can be raised and moved as a whole in various directions, the elbow is fixed, and its movements impossible.

Fixation of the elbow is commonly effected by bandaging the arm to a rectangular wooden splint, a procedure which, in the class of cases briefly described above, aggravates the swelling by the pressure of the bandages above the joint. When the iron splint is applied, bandages encircle only the thorax and wrist, and do not compress the venous channels over-handicapped by the sudden effusion. A state of physiological as well as physical rest, which cannot but be beneficial, is thus effected.

But the use of the splint is not limited to cases of injury. A case of synovitis which made no progress whilst the limb was bound to an ordinary rectangular splint, at once improved when the iron splint was substituted. During convalescence after excision of the elbow, and in cases of disease of the elbow, especially when bony ankylosis is desired, it is also of service. The space between the elbow and shaft of the splint permits the application of dressings, or allows incisions to be made without disturbing either limb or splint. The splint acts as a sling, the weight of the arm being supported by the shoulder; it is thus comfortable, and one patient wore it continuously with benefit and comfort for eight months. It is not taken off at night, and the shoulder-piece can be effectually concealed within the armhole of the vest or dress, and, as a rule, patients prefer it to the wooden splints.

Messrs. Arnold and Sons, of West Smithfield, E.C., make the splint, with padding for the shoulder and hand-pieces as shown in the drawing.

Clinical Records.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

Meningitis—Death.

Under the care of Dr. ARMAND SEMPLE.

Notes by E. TULL-TURER, Registrar.

G. W. K., boy, *æt.* 5, admitted on March 4th, 1888.

Family History.—Parents healthy. History of phthisis in some members of the mother's family. One brother died in the hospital from the effects of a scald. One other child alive and healthy.

Personal Medical History.—Three years ago had measles. Never had scarlet-fever, pertussis, or rheumatism. For the last month the boy has complained at times of pain in the head and eyes. Ten days ago he began to be ill with the symptoms of a common cold; at the same time a discharge from his right ear, which had been rather profuse before, stopped. He was sick, and his motions, which were at first loose and yellow, became constipated. Before this he had been, as a rule, a quick, cheerful boy, but now he became drowsy and unable to attend school. He had no eruption on any part of his body. No history of any blow on the head.

On Admission.—A light-haired, blue-eyed boy, rather thin. He lies in a drowsy state, crying when he is disturbed. Tongue white. No dulness over lungs; good deal of loose crepitation to be heard. Abdomen retracted; skin over the abdomen inelastic. Urine, 1035—thick, no albumen or sugar. E. T., 99.8; P., 100—regular. Ordered *mistura quinis*, ʒij, *ter die*.

15th.—M. T., 100.6; P., 114; R., 24. Has been sick. Very drowsy, and unwilling to be disturbed. Wanders a little. Lies on his right side. Pulse in the evening, 102—intermittent. E. T., 100.6. No *tache cerebrale*.

16th.—M. T., 99.2. Called out and wandered last night. Answers questions. Cries out when touched. Bowels constipated, but relieved once after an enema. Pupils dilated; respond sluggishly to light. No *tache*. E. T., 100; P., 98.

17th.—Bowels constipated; two grains of calomel had no effect; they were opened once after half a drachm of *pulv. jalapæ co.* Lies on his back, unwilling to be disturbed. M. T., 100; P., 132—intermittent; R., 24—regular. Pupils do not respond to light. Plantar reflex exaggerated. Cremasteric reflex normal. Superficial abdominal reflexes could not be obtained. No ankle clonus. E. T., 101; P., 78. In the evening he had a brief convulsive attack, beginning with a sharp cry. His teeth were clenched, and his arms became quite rigid. During the fit his right pupil became widely dilated, the left one contracted. He had another fit at 11.30 p.m. Ice-bag ordered to head. Given *mistura rhei cum soda*, ʒj, *ter die*.

18th.—Had another fit of a similar character at 1 a.m., but otherwise slept well. The right pupil is widely dilated and insensible to light; the left pupil normal, but responds sluggishly. Slight ptosis of the right upper eyelid. On examining the right eye with the ophthalmoscope, the vessels were large and very tortuous; the edge of the disc was blurred, especially at the upper part. Grinds his teeth incessantly. M. T., 99.6; E. T., 99.8.

19th.—M. T., 97.8; P., 78. Had two fits last evening. Pulse, irregular. Lies in semi-comatose state. Pupils as before. Ptosis on right side more marked. Abdomen retracted. Plantar reflex normal. No ankle clonus. In the evening he could not swallow, so he was fed by nutrient enemata every three hours. E. T., 97.6; P., 78. Has had eight fits during the day, during one of which the back became very much arched. Face cold. Bowels very confined. Given two grains of calomel. Hot bottles put to feet.

20th.—M. T., 98.2; P., 72—intermittent; R., 30. Lies in the same condition on his right side. Has had fits of similar character every half-hour during the night. Bowels open once involuntarily after the calomel. Retains the nutrient enemata. Passes water involuntarily. Plantar reflex diminished. Right upper extremity rigid; the thumb is strongly flexed across the palm of the hand, and covered by the strongly-flexed fingers. Pupils and right disc as before; left disc, normal. E. T., 99.2.

21st.—M. T., 100; P., 120; R., 30—irregular. Lies in the same state on his right side. No *tache cerebrale*. Saliva dribbles out of his mouth. Pupils the same; if anything the left one is slightly dilated. Ptosis well marked on the right side. Abdomen retracted. Both upper extremities are rigid; the right hand and wrist is more strongly flexed than before. The lower limbs are slightly rigid. Passes motions involuntarily. No bed-sores. Face rather flushed. In the middle of the day the breathing was noisy, accompanied by violent puffing of the cheeks. Towards evening the breathing was of a Cheyne-Stokes character. He died at 8.30 p.m.

Autopsy made twenty hours after death by E. Tull-Turer: Body thin. Both pupils contracted. The fingers and thumbs of both hands are strongly flexed. Hypostatic congestion well marked on the right side of the head and neck, and on the right ear. On removing the skull-cap the dura mater looked congested—sinuses full of fluid blood. There was a little lymph on the left side of the median fissure. No tubercles to be seen anywhere, though careful examination was made of every part of the brain and membranes. There was considerable excess of cerebro-spinal fluid. Ventricles normal. The dura mater at the anterior end of the lateral sinus and around the superior petrosal sinus was a good deal thickened, very closely adherent to the petrous bone. The right lateral and superior petrosal sinuses contained thick, semi-clotted blood. No pus to be found in the brain or sinuses. No caries of the temporal bone. On opening the right tympanic cavity, muco-pus was found in considerable quantity there, and in the mastoid cells; left tympanic cavity contained no pus. Lungs congested; frothy mucus exuded from the tubes on section of the organs. The upper lobes of both lungs, especially the right, contained a considerable quantity of miliary tubercle; no cavities. Pleuræ normal. Heart tissue normal; valves healthy; pericardium normal. Kidneys congested; capsule easily stripped off. Spleen rather hard; no tubercles. Liver normal. Abdomen: No peritonitis; vermiform appendix enlarged and thickened; on opening it, some pus was squeezed out; no foreign body or ulcer found in the appendix; the intestines were opened; the cæcum and ascending colon contained a soft mass of semi-solid fæces, yellowish and black in colour, in which here and there were small quantities of pus. In the small intestine, about one inch and

a-half above the ilio-cæcal valve, was a ragged irregular ulcer, with its floor apparently formed of sub-mucous tissue—its long axis was transverse to the long axis of the bowel. No enlargement of Peyer's patches in the vicinity. Ilio-cæcal valve healthy. Mesenteric glands slightly enlarged, not caseating or suppurating. Bladder full of healthy urine, though shortly before death he had passed his water involuntarily.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

SUB-SECTION OF STATE MEDICINE.

THE Sub-Section of State Medicine met on Friday evening, April 12th, Dr. C. A. CAMERON, President of the Sub-Section, in the chair. Dr. T. F. POLLOCK, Sub-Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

A NEW TEST FOR ORGANISMS IN WATER.

Dr. POLLOCK read a communication from Dr. R. Angus Smith, F.R.S., of Manchester, disclosing his newly-discovered test of the presence of organisms in water. It consists of rendering the water thick by dissolving gelatine in it. If pure the gelatine cylinder remained long unaltered, but if the water be impure from the presence of organisms the gelatine round the organisms becomes liquefied and globular, the organisms remaining solid at the bottom of the spheres.

The PRESIDENT exhibited photographs of test tubes of water which had been thickened by a solution of the purest fish gelatine and then exposed to the action of light. When the water was pure it remained translucent, but when bad, bubbles were rapidly formed and the bacteria which appeared to be in the water began to act on the gelatine, breaking it up and rendering it soluble. A rapid movement of gas was observable. Where the bubbles or balls appeared to be spherical they were aggregations of bacteriæ. This change took place quickly, almost in twenty-four hours. But a peculiarity of the test was this, that it was only applicable where infusorial animals were present. For instance, peaty water, in which there were no animalcules or bacteriæ, would stand without breaking up the gelatine.

Dr. POOLE inquired how much gelatine was used?

The PRESIDENT.—Just what would make the water thick.

Dr. R. MONTGOMERY.—Is it a test which is only applicable where bacteriæ are present?

The PRESIDENT.—That is all.

Dr. R. MONTGOMERY.—Bacteriæ are the most deadly of all poisons in water, and in that aspect the test seems most valuable and ready for anyone to use, although not being a scientific chemist.

The PRESIDENT.—In order to change the gelatine, bacteriæ must be present. Organic matter that is not putrescent or infective will not do it. This is the first public body to which the test has been communicated, and I think Dr. Angus Smith deserves our thanks.

The thanks of the Sub-Section were voted to Dr. Angus Smith.

RESULT OF CONSANGUINEOUS MARRIAGES.

Dr. T. FITZPATRICK, as the senior member present, then took the chair whilst

The PRESIDENT read a paper on consanguineous marriages in relation to deaf-mutism. He described the practices and prejudices in respect of consanguineous marriages amongst ancient and modern nations, civilised, barbarous, and savage. He next reviewed and criticised the memoirs on the subject of the effects produced by the marriage of cousins. On the whole, the evidence seemed to show the effects were somewhat injurious. The statistics in reference to mutes published in the Irish census reports for 1881 and the previous decennial reports were closely examined by the author. It appears that in Ireland in 1881 there were 5,136 mutes, of whom 135 were the children of first cousins. The author endeavoured to ascertain the proportion of the population who were children of first cousins. He ascertained that amongst nearly 8,000 persons the proportion was only 0.57 per cent., or less than one-fourth of the rate amongst deaf-mutes. As the statistics were in great part collected amongst Protestants, the author believed that there were not in all Ireland one person in two hundred the offspring of

first cousins, as marriage between persons so related was very rare amongst Catholics, who formed three-fourths of the population of Ireland. The general conclusion arrived at was that consanguineous marriages were a cause of deaf-mutism.

The CHAIRMAN (Dr. FITZPATRICK) observed that the paper was the most remarkable he had heard at any public meeting for a long period, making it apparently clear to demonstration that the marriages, particularly of first and second cousins, were productive of deaf-mutism. In his own long experience he found almost every case of deaf-mutism to be the result of the intermarriage of near relatives. To take an example, he found not only was one child a deaf-mute, and another insane, but the whole family partook of degeneration of the nervous power. They entered early into marriage and never prospered in society. Scrofula, deaf-mutism, insanity, and other characteristics exhibiting weakness of brain and muscular power resulted from those marriages.

Dr. EUSTACE thought the question must be considered very much from the animal point of view. The human family was at the head of all other animals, so that the question might be elucidated by what took place with other animals who according to their anatomy and in many respects were our relatives. It was well known to all persons who tried to breed first-class animals that close in-and-in breeding resulted in very great deterioration of the species, and also that animals when left to themselves did not select their nearest relations for sexual intercourse. Even that much-maligned animal the female dog would invariably select, not a dog of her own peculiar breed, but that of a different race altogether, both with regard to size and colour. That intermarriages were productive of many evils as a general result he held to be a fact. With regard to mental disease, he believed the health of the intellect in the human family depended more largely than they were in the habit of considering on the bodily health or physique, although there were exceptional cases in which very poor specimens of humanity were gifted with brilliant intellect. In the treatment of the insane his leading principle was to get up the bodily health, and as it improved the mind improved.

Dr. COX mentioned an instance in which two cousins got married. Both were healthy and without any special indication of disease. The result was that of the offspring, one, a very fine girl, died of phthisis, another developed symptoms of lung disease, but happily escaped consumption, and a third developed spinal disease. Again, in animals other than the human species, disease was apt to occur in those nearly related, while in the vegetable kingdom plants of the same kind which were barren were often fertilised by the pollen of others.

Dr. WILLIS instanced a case he saw some years ago near London of a sick child whose father and mother were deaf and dumb, and it was through their children, all of whom could speak, he came to a decision about the ailment.

Dr. WRIGHT concurred as to the damage ensuing from the marriage of near relatives, and referred to Darwin's experiment on pigeons, and to the difficulty of keeping a pure breed of poultry, as illustrated by the fate of the bantams brought from the palace of Pekin, and by the destruction of another favourite breed of fowl, the white-crested Polish. He did not believe that female animals selected the male. The converse, he thought, was the rule.

Dr. EUSTACE said such selection had brought the term of reproach upon bitches, and their offspring were called curs.

The PRESIDENT (Dr. CAMERON) replied, pointing out that his statistics were necessarily incomplete and restricted. It would be indispensable to ascertain how many of the whole population were the children of first cousins before drawing a definite conclusion.

DISPOSAL OF SEWAGE IN VILLAGES.

Dr. W. M. A. WRIGHT, of Dalkey, read a paper containing suggestions for the better disposal of sewage in Irish country villages. It must be admitted, he contended, that in the better class of Irish villages, where each cottage is provided with a privy and ashpit, a serious nuisance is frequently caused by their faulty construction, and the filthy manner in which they are kept, the receptacle of the privy being generally too large, some too deep below the level of the ground, and communicatin with the ashpit, which is also too large, deeply sunk, and uncovered by a roof. Both privy and ashpit being undrained, their contents mix, and form a fætid, semi-

fluid mass of liquid excreta, vegetable refuse, and fine ashes, which is frequently augmented by the surface drainings from the neighbouring pig-stye. Such a state of things as this is dangerous to health, both directly from its gaseous emanations, and also indirectly through the soakage into the neighbouring soil, and it is for such cases that the improvement is suggested. The poorer class of Irish villages, which consists for the most part of irregular, detached, mud cabins, being quite destitute of any kind of privy or ashpit accommodation, will not be considered, as in their case the nuisance just described does not exist. It must be remembered that any proposed scheme to be practical must be cheap both in construction and working, and simple, as both the rural boards of guardians, who are the sanitary authorities and the owners of the cottages, would be certain to reject any costly plan. The expense of construction would prevent the adoption of either the water carriage, the dry earth, the simple pneumatic or Liernur's system, and the trouble and expense of the necessary scavenging put the pail systems out of the question. In fact, the method most likely to be successful in practice is one to improve away the more dangerous properties of the privy and ashpit. The best way to effect this is first to roof over the ashpit and have no communication between it and the rafters of the privy; next, to construct the privy with a small receptacle, the floor of which should be carefully cemented and sloped towards the back wall, where an open grating is fixed to permit the escape of the urine and leave the fæces dry. The urine should then pass into a sewer-pipe, which is common to as many cottages as possible, probably to all on one side of the street, and which also receives the house-drops and the liquid manure from the pig-styes and stables, but no rain-water, and empties into a cemented and well-ventilated cesspool situated in a grass field as far as practicable from the village. When the cesspool becomes full it can be readily emptied by means of a pump with a long hose pipe attached to its nozzle, and its contents distributed by irrigation over the field in which it is sunk. As it is full of a highly concentrated liquid manure, which forms a most valuable application as a fertilising agent, the results to the pasture will be most beneficial, while, owing to the well-known properties of growing vegetation, the sewage will become rapidly deodorised and rendered innocuous. The solid excreta which remained in the privy can, when the ashpit is being cleaned, be mixed with the dry ashes, and so removed without causing any nuisance dangerous to health.

Dr. WILLIS considered the author's proposal impracticable in certain parts of Ireland. He related an instance of a gentleman getting privies built for his tenantry in the county Limerick, but they pulled down the privies, except one man, who got the name of "Jack the gentleman," and he at length had to make a compromise with local opinion—he let the privy remain up, but did not use it. Farmers even with 200 or 300 acres had not a privy, but simply a causeway extending to a deep ditch.

Dr. POLLOCK said Dr. Wright had, no doubt, brought forward a practical paper, but his sanitary measures were in great part retrograde, especially in suggesting the introduction of the old cesspool again. Earth was a great deodoriser, but, of course, its effect was limited to deodorising a certain quantity of matter. As an illustration, he knew of a cesspool at the end of a long garden which had so saturated the clay that a spadeful could not be turned up without producing the most abominable stench. A patient of his had nearly lost her life from the same cause.

Dr. R. MONTGOMERY mentioned having seen, in the neighbourhood of St. Patrick's Cathedral that day, a large heap of manure close to a room six or eight feet square, in which there was a child, set. 10, sick with fever. The room was in a dreadful state of filth. A woman lived there with seven children, along with her husband, who had 14s. a week.

Rev. H. SKEDDALL testified to the deplorable want of sanitary precautions among the peasantry all over Ireland. He had often pointed out the risks they ran of getting fever.

Dr. H. V. DILLON indicated the danger of cesspools polluting wells from which the country people obtained their supply of water to drink.

Dr. Cox did not see any reason, except dietary, why human excrement should be more deleterious than that of other animals, which, when exposed to the atmosphere for a time, became deodorised and practically inoffensive. Hence it was that, having regard to the habits of the peasantry who went some distance from their dwellings, the excrement was not productive of the danger that might be supposed, but from

exposure it became reconverted into its mother earth. Indeed, he could conceive that to be less harmful than where the excrement was conveyed in sewers and discharged into the tide and then washed back again. At the same time, he did not want to defend the habits of the peasantry. He suggested the innocuous disposal of excrement by incineration.

Dr. DOYLE concurred as to the effect of atmospheric exposure in rendering excrement harmless.

The PRESIDENT would have the whole material collected in one receptacle, like an ordinary liquid manure tank, which was provided in every well-regulated farm-yard in Scotland and England, and also in parts of Ireland. He believed the burning of excrement would be the course adopted in future, as was done in Glasgow, Manchester, Bolton, and other towns at present. When incinerated, it was reduced to an ash, which was used as a building material. The excrement was collected in pails from the house, the man throwing a pinch of carbolic acid into each pail, and thus preventing any noxious odour. Every town required some system that its local condition rendered more desirable than another. In Dublin he was doing all he could in inducing the people to give up filthy privies. There were 2,000 water-closets substituted for privies, while there were 16,500 water-closets as against 11,000 privies; and he hoped there would be no privies worth speaking of in the course of five or six years.

Dr. WRIGHT replied, it was amusing that the first speaker accused him of proposing a scheme too advanced for country villages, while Dr. Pollock told him he was retrogressing. His answer to the first speaker, and also to Dr. Cox, was that he did not propose to deal with isolated dwellings at all. Instead of the defective system at present existing, he would employ a pump with a hose, fifty or sixty feet long, and irrigate a field with the sewage, scattering it over a large area, to be absorbed by the grass. He would have the cesspool in such a position that the sewage would flow away from the water supply, and not towards it. The solid excrement would be pretty well dried by the current of air circulating through the privy, and it could be mixed with ashes when thrown out.

The Sub-Section then adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

In our report of the last meeting of this Society (*Medical Press*, May 9) the following passage occurs:—"Dr. F. G. Edwardes showed a specimen of dilatation and hypertrophy of the bladder and ureters," &c. This should read—Mr. F. Swinford Edwards showed a specimen, &c., &c.

THE UNQUALIFIED ASSISTANT SYSTEM AND THE ILLEGAL SIGNING OF DEATH CERTIFICATES.

(Continued from page 404.)

THE RISE AND PROGRESS OF THE SYSTEM OF EMPLOYING ASSISTANTS.

THE employment of assistants by medical men is such a natural outcome of the organisation of labour that it must have been customary from the earliest times in which our occupation became a means of livelihood. In England, five hundred years ago, it was considered a matter of course that a "doctour of physike," whom Chaucer describes as a "veary perite practisour," should have "full ready" at hand dispensing assistants to send out his eleutheraries, and, when their master rode forth on his holiday trip, to keep his patients together to the mutual advantage of both parties—"For each of them made t'other for to winne." They acted as what is now called a "stop-gap." These assistants were legally "grocers" under the control of the company formed about thirty years before, and probably never hoped to be medical men. But many years after the custom was made a means of education through the establishment of the apprenticeship system under the Apothecaries' Company, and down almost to the present time, the apothecary's apprentice or surgeon's pupil was, in fact, an assistant placed by the law under strict domestic and professional discipline, and bound to receive such training as would be useful during his service to his master, and to himself in after life. (A graphic sketch from a favourable point of view of what an apprentice was half a century ago may be found in a "Memoir of a Country Surgeon." Reeve Bros.

1845. In *Medico-Chir. Library Tracts*, B. 154.) The disuse of apprenticeship and the requirements of preliminary education have deprived practitioners of the help they got from these incipient students. And at the same time the rapid increase of the population, and the yearly growing demand on practitioners for their services by classes formerly dependent solely on charity, or contented to forego those services altogether, have swelled the ranks of assistants, and recruited them with persons who look to be repaid for their work in money rather than in knowledge. The *bond fide* "pupil," who pays for and receives instruction from, while he is assisting, his master, is rarely to be found now, and when mentioned in this "Statement" will be distinguished from the assistants to independent practitioners who adopt the occupation of as a means livelihood, either during studentship or later in life.

The employment of "assistants" is of great advantage to the community in facilitating the establishment of clubs, provident dispensaries, and branch practices, for the supply of medical and surgical aid under the supervision of experienced practitioners among populations which cannot afford the full payments required in private practice. These populations could not support a local practitioner, they are very often distant from places which do support one, and in manufacturing districts are peculiarly exposed to sudden and grave accidents. They are, as a rule, very independent, and often prefer going without medical aid, or getting it from some ignorant neighbour or dishonest pretender, to a resort to charity. To lend a helping hand to such independence is thought by many philanthropists to be a duty.

The establishment of clubs, dispensaries, and branch practices, which is extended yearly, is of equal advantage to the medical practitioner as to the public; for by this means he is enabled to tap a new source of income, which, fed by such a wide area, must be in the aggregate very large; and the generally adopted custom in the manufacturing districts of payment by salary from a rate on men's wages, collected through their masters, is a safer, pleasanter, and more independent mode of receiving an income than either taking ready-money fees or sending in bills. In the prospectuses of practices for transfer the number of "clubs," "dispensaries," and "collieries" is frequently inserted as a special recommendation.

The number of these posts held by a single responsible surgeon is sometimes very large. In the *Medical Directory* for 1882 one medical man returns the names of fourteen collieries and clubs and one Union to which he is surgeon.

Without assistants it would be impossible to work these several kinds of public practice. There are also many private practices which must be extensive in order to yield a proper income, and therefore require the aid of an assistant. For midwifery practice this aid is especially required. And in certain populations it is required periodically, and temporarily only; while there is not such constant work as would justify the introduction of a partner or an additional independent practitioner. For example, in riverain and maritime villages, inhabited by deep-sea fishermen, all the husbands go to the Dogger Bank or elsewhere in a body for many weeks, sending home their fish in a steamer; they come home all at once, and after a time their wives require obstetric help all at once. The same thing happens in a minor degree among the families of haymaking and harvesting gangs. Again, in colliery districts, grave accidents are often epidemic in consequence of sudden meteorological changes, and an unusual number of hands temporarily required for surgical aid. Again, a practitioner in charge of public bodies is called upon from time to time to exercise a sanitary supervision which is impossible without assistants, but which becomes annually more and more important. So that year by year we may expect the demand for assistants to increase, and the necessity for recognizing as legitimate the long-established custom of centuries to become more imperative.

Assistants are divided into those who are registered as "qualified" by the usual examination and the "unqualified." To the latter I have understood the scope of this inquiry to be limited.

CHARACTERISTICS OF UNQUALIFIED ASSISTANTS.

The "unqualified assistants" may be classified as follows:—

- (a) The "apprentices" or "pupils" who, without having received any previous medical education, are employed in doing their master's work.
- (b) The students who during their hospital career are so employed.

(c) Assistants who have more or less attended hospital lectures, &c., but have failed to obtain qualification.

(d) Assistants who become such without previous professional knowledge, and pick up what they do know by doing their master's work, never intending at any time to become qualified.

Or, to put the matter less formally, unqualified assistants are to be found of all ages, from the boy who is endeavouring thus to pick up a knowledge of his profession before he goes to a medical school, to the ancient heir-loom who, by the transfer of a practice, has been handed over to successive masters and has become a sort of institution in the place. Between them lies the partially qualified student who has passed the preliminary and one or more professional examinations, and is looking forward to obtaining qualification. And very many are the middle-aged men in whom this ambition has died out, who settle down and marry, spend the money they had saved up to pay the expenses of becoming licensed, and never rise beyond the false position where they have placed themselves. A physician at Scarborough writes:—"I know at the present time at least half a dozen men over 40 years of age who have been acting as unqualified assistants for many years, and who have no earthly prospect of ever being qualified."

As of all ages, so are they of all qualities, from the honourable youth who is trying to save his friends the cost of his keep while attending the hospital, to the uneducated grocer, miner, or retired sailor. Among the former some are pupils, while the latter are mere servants, though they take charge of the sick, often at a considerable distance from their master or coverer. Some medical men keep both at once, the pupils in their own houses and presumably receiving instruction, the others left to their own devices or inhabiting different branches. Sometimes qualified and unqualified assistants are kept together by the same registered practitioner, and have the same duties assigned to them. The classes above enumerated merge one into another by many gradations, so that it is difficult for even the man himself to say to which he belongs.

It is difficult to make an accurate calculation of the numbers of unqualified assistants, for shame seems to prevent the giving of information on the subject. "The people able to give it are just those who might wish to withhold it" (Leeds). The writer of a series of articles in the *Medical Press* estimates them at 3,000 in England and Scotland, but does not say on what data that figure is based. The following examples, however, give some idea of their numbers in proportion to qualified assistants and employers. In Jarrow Division, County Durham, Mr. Scott reports, from the County Constabulary Office, that there are sixteen qualified medical men in practice, and seven (or eight) unqualified men who act as their assistants. In one town of 73,000 inhabitants, with twenty medical men, there are said to be ten unqualified assistants (*Medical Press*, April 19th, 1882), and you have information of five at least being in the service of one employer near Sheffield. A gentleman in Wales has, since May, 1868, employed thirty assistants, usually two at a time, of whom twenty-four were qualified and six unqualified, not counting a dispenser and a pupil. He is on conscientious grounds giving up the use of the unqualified. During the last four years the number of visits paid has been 115,072, patients attending personally at the dispensary not counted in. This gives upwards of twenty-six visits daily by each of the three persons engaged, besides a good deal of indoor work. At Halifax you are informed there were lately sixteen unqualified assistants, but that the number is now reduced to seven, in consequence of the personal efforts of the younger practitioners to put down the system. In the neighbourhood nearly all the country practitioners have unqualified assistants—numbers unknown. In an eastern fishing town there are five assistants employed, three of whom are qualified, two unqualified, one of whom practises on his own account under cover. In the neighbourhood there is one unqualified assistant, practising with his brother, who is a registered medical man. More than half of the annual births are attended by an unqualified assistant. In Manchester "about 30 per cent. of the practitioners of over five years' standing keep unqualified assistants of some kind; about 8 per cent. keep qualified assistants. In the towns round Manchester with large working populations the number of unqualified assistants is greater still."

In a large area in Staffordshire, with about 250,000 inhabitants, including six towns and many collieries and potteries,

there are stated by a hospital surgeon to be thirty-nine resident medical men, who employ thirteen unqualified and three qualified assistants. Of the unqualified, one practises quite independently, and is only "covered" by occasional visits from his principal. Pupils are not included. In Sheffield there has been for ten years a dispensary in private hands which has employed unqualified assistants and wrought much evil. Since last spring two similar establishments have been added, one of which has thrown off branches into neighbouring villages, all worked for gain. At a large manufacturing city, supporting nearly 100 registered practitioners, the influence of the unqualified assistant interest is so weighty, that the leading physicians, though opposed to the system, decline to furnish any statistics of the numbers, lest they should have a majority against them in their local Medical Society and a feud be stirred up.

As to their competency to attend the sick, I learn from a well-known surgeon in Hallamshire that "It is really the exception to find one thoroughly competent. But occasionally we get a practical man who from poverty or some unforeseen circumstances is obliged to find the means of completing his education by taking the post of assistant." And again, it is stated by another correspondent, well capable of judging, that "as a rule unqualified assistants are incompetent to treat the sick." It would appear, then, that the old-established unqualified man does not improve by keeping, and that the younger one who seeks the post only as a temporary expedient is the more efficient of the two. To others, however, he is more acceptable, from being "acquainted with the Shibboleth of the profession," and with "the routine of practice," as we are informed in South Wales.

Examples of ignorant *mala-praxis* by the unqualified are numerous, as may be supposed; but to quote them would require more investigation than lies in the power of the Committee. Moreover, taken alone, they would be irrelevant, and might possibly be answered by cases of alleged misconduct among the registered assistants, who are not the subjects of our inquiry.

A well-known general practitioner pertinently remarks, "Training of this kind does not make a good practitioner." "To the profession generally," a physician of Leeds says, "I believe the use of unqualified men is a convenience; but to the public, and so far as the best interests of the assistants themselves in the long run go, to them too it is a great evil."

In respect of provision for the future, as the last quoted correspondent implies, an unqualified assistant is indeed most unfortunately situated. He is liable to discharge at any time, with or without a character, the granting of which has been decided to be optional (see *Medical Directory*). In this respect he differs, greatly to his disadvantage, from an indentured pupil or apprentice, whose position is secure if he has taken care to pay a small premium. This, however, cuts both ways, and specimens are given, in the letters submitted to the Committee, of unqualified assistants who have discharged themselves at a week's notice, conduct very inconvenient to the master; for his remedy by civil action is doubtful, however great the damage done to him. This danger is by some medical men provided against in a formal written agreement, of which a specimen in print is filed, and which is stated to be a sufficient safeguard.

(To be continued.)

France

[FROM OUR SPECIAL CORRESPONDENT.]

THE greater part of the séance of the Académie de Médecine last week was occupied by M. Pasteur, who came up expressly from the country, in order to defend himself from the allegations of M. Peter, who at a former meeting showed himself antagonistic to the theories of the celebrated discoverer of microbes. In a lengthy communication, M. Pasteur endeavoured to refute the opinions of his adversary, and denied that his vaccinations were attended with fatal results. He reproached M. Peter with being entirely ignorant of the subject in question, and added, "I am not a

doctor nor even a veterinary surgeon and I often regret it. If I were younger, or even as I am, if I had better health, you would see me on the seats in the gallery. When I obtained the honour of being called to this Academy, I rejoiced in the idea that I was going to learn from you many things of which I was ignorant, but I consoled myself with the thought, that the path I had chosen, although deviating a little from the well beaten road of medical science, would perhaps contribute its share, however small, to the benefit of that science. To hear my learned friend talk with such contempt of chemists and physiologists, who touch the question of diseases, one would think that he was speaking in the name of a science whose principles were founded on a rock. Did he want a proof of the little advance that is made in therapeutics? He will find it in the fact that for the last six months a discussion is going on as to whether typhoid fever should be treated by this or that method, or not at all? And when on the eve of solving the question of the etiology of this disease by the microbia M. Peter has the audacity to cry out, 'what do I care about your microbes.' M. Peter thinks that because I turned my mind to chemistry, physics, and physiology, I should know nothing, but a labour of forty years permits me to defy such insinuations. I glory in one thing, and that is, that the great discovery of the attenuation of virus (charbon) by vaccine can be considered as wholly French." (Prolonged applause.)

At the Société de Chirurgie, M. Cazin said he could not accept the opinion emitted some days ago by M. Parrot, in reference to the relation of rickets to syphilis. Contrary to the assertion of his eminent colleague that rickets was always the result of congenital syphilis, he could see no parentage between the two affections. He collected a certain number of examples of rickets without syphilis and syphilis without rickets. Another fact confirmed him in this opinion, and that was, the treatment which, when consisting of mercury and iodide of potassium as forming the anti-syphilitic treatment, had not only no effect on rickets but was positively injurious. If rickets were the result of a diathesis it would be that of struma and certainly not syphilis. M. Despres sided with M. Cazin, and said that whereas rickets can be cured by cod-liver oil and phosphate of lime when not too advanced, congenital syphilis is nearly always fatal, no matter what the treatment.

Department of Lunacy.

BARNWOOD HOUSE ASYLUM.

THE report of the Barnwood House Lunatic Hospital, at Gloucester, for the year 1882, which has just reached us, clearly shows that that useful institution is pursuing its beneficent course with uninterrupted, and indeed with increasing, success. And the secret of that success it is not difficult to discern. It is indeed plainly set forth by the Managing Committee, who intimate that they are well aware that the excellent reputation enjoyed by the institution is due almost entirely to the admirable manner in which it is conducted by Dr. Needham, aided by the voluntary assistance of Mrs. Needham. The Committee take the opportunity of expressing their appreciation of the devotion of Dr. Needham to the interests of the establishment and its inmates. The Commissioners in Lunacy, who are, as a rule, and very properly, cautious and formal in their bestowal of praise, speak out freely in

the case of Barnwood House, and after noticing its flourishing condition and judicious management, echo the sentiments of the Committee as to the value of the services of its medical superintendent. A public asylum, like a public school, takes its tone and complexion from its head, and must rise or fall in general estimation according as he is capable and energetic, or the reverse, and Barnwood House seems to have been fortunate enough to secure as its head a sort of asylum Arnold, who infuses into all who act under him something of his own zeal and practical humanity, and who is steadily extending its usefulness and reputation. Barnwood House contained on the 1st of January last, 129 patients, 160 having been under care during the previous twelve months. Notwithstanding that a considerable number of patients are received at reduced and, indeed, merely nominal rates of board, the profits on the operations of the year amounted to £5,445. This profit was earned, too, while the utmost liberality was displayed in the administrations of the hospital and treatment of the patients. We are glad to notice that the Committee are making provision for the pensioning of old and faithful servants.

BROADMOOR CRIMINAL LUNATIC ASYLUM.

No fuller, clearer, or more interesting lunatic asylum report reaches us than that of the Broadmoor Criminal Lunatic Asylum. It presents a comprehensive and masterly survey of operations of the establishment, and supplies also much valuable medical information in the shape of summaries of cases, records of sickness and of the appearances observed at post-mortem examinations. The report for the year 1882, which has just been published, contains a modest reference to the alarming assault which was made on the able and accomplished chief of the Asylum, Dr. Orange, by one of the inmates on the 6th of June last. The assault consisted in a violent blow on the head with a heavy stone slung in a handkerchief, dealt while Dr. Orange was seated at a table reading some papers, by a patient who was standing beside him. The perpetrator of the act was the same man who fired at the late Master of the Rolls, whose loss we have been so recently lamenting, and the two murderous attempts of this lunatic seem to have been prompted by the same motive, viz., an insane desire to attract attention to a conspiracy of which he believes himself to be the victim. It is gratifying to know that Dr. Orange, although seriously injured and for a time incapacitated for work, has been able to resume the responsible and anxious duties which he has so long performed with distinguished success. When the nature of these duties are considered it must certainly create surprise that Dr. Orange's manner of discharging them has not obtained more liberal recognition. Although at the head of the State Asylum, and exposed to constant danger and ceaseless anxiety in guarding the public safety, Dr. Orange actually receives a less salary than the superintendents of several county asylums, and his remuneration has not been increased since he succeeded to his present office some twenty years ago. The Government ought certainly to look to this matter without delay and show a just appreciation of the labours of an invaluable public servant.

The average number of patients resident in Broadmoor

during last year was 495. Seven patients in all, five of whom had been convicted of murder, one of larceny, and one of arson, were discharged recovered, and eleven patients died. Since the opening of Broadmoor in 1863 1,349 patients have been admitted into it, of whom 345 had been guilty of murder, 224 of attempts to murder and maim, 104 of burglary or housebreaking, 323 of larceny, 91 of arson, 19 of manslaughter, 13 of rape, 17 of unnatural crime, and the remainder of a great variety of minor offences. Considering the antecedents and tendencies of the lunatics assembled together in Broadmoor, it is indeed a subject of congratulation to the officials that last year passed without a suicide, escape, or serious accident of any description.

THE DUNDEE ROYAL ASYLUM.

UNEXPECTED delays have occurred in the opening of the new lunatic asylum at Dundee, but the buildings are now ready for occupation—indeed, an advanced guard of working patients have been residing in them for some time, and preparing them for the reception of the main body of the inmates of the old establishment. The new institution has been carefully designed and fitted up with all modern improvements, and we may confidently anticipate for it a prosperous career under the guidance of its gifted superintendent, Dr. Rorie, whose management of the old asylum, in spite of all the difficulties arising out of irremediable structural defects and archaic arrangements, has been so praiseworthy. Four hundred and twenty-six patients were under treatment in the Dundee asylum during last year.

DERBY COUNTY ASYLUM.

DR. MURRAY LINDSAY presents, as usual, a thoughtful and satisfactory report on the state and operations of the Derby County Asylum during last year. Frequent applications, he intimates, are made to him for the admission of private patients, but these he is, of course, unable to meet, having only sufficient room in the Asylum for pauper lunatics chargeable to the several unions in the county. Such applications, however, reveal the want which exists for suitable provision for insane patients of the lower middle class, whose friends are able and willing to pay a moderate sum, but whose means do not enable them to pay the charges of private asylums. There can be no doubt that pauper asylums are, to some extent, misappropriated, unavoidably, perhaps, in the present state of the law, and for the reasons just given, by patients being sent to them, by the assistance of the union authorities, for whose maintenance ten or fifteen shillings a week might be, and is, paid, and who are not, therefore, really paupers. The visiting justices of the Derby Asylum called attention to the subject in their last report to Quarter Sessions, and all possible publicity should be given to it, so that charitable persons should be made acquainted with a channel in which their benefactions might flow with the certainty of doing a vast amount of good. Separate asylums for lower middle class lunatics are certainly very urgently needed.

Dr. Lindsay has had 548 patients in all under his care last year, and is able to report a high rate of recovery

(amounting to 43·2 per cent. of the admissions), and a low death-rate (only 8·2 per cent. of the average number daily resident). Differences of opinion may exist as to the practical wisdom of the step taken in depriving the patients of the Derby County Asylum of the beer ration which they have hitherto enjoyed without supplying them with any substitute, such as skim milk or butter-milk, but this, at any rate, is indisputable, that that step has been taken from excellent motives, and that the Asylum under is kind and careful management.

WOODILEE ASYLUM.

DR. R. BLAIR, Assistant Medical Officer of Gartnavel Lunatic Asylum, was, on the 9th inst., appointed Medical Superintendent of the Woodilee Asylum, Lenzie, at a salary of £500 per annum, in room of Dr. Rutherford, who has now charge of the Southern Counties Asylum, Dumfries.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 16, 1883.

THE MEDICAL BILL.

THE second reading of the Bill was not taken on Thursday, although—up to Wednesday—it stood first on the notice paper of the House of Commons. It will, therefore, not come on until a few days after the re-assembling of Parliament on the 21st, and the Committee stage of the Bill, at which the principal contentions will arise, will probably not be taken for the next three weeks.

Meanwhile all parties interested are actively preparing for the occasion. The General Council of the British Medical Association is to meet at Birmingham on to-morrow the 17th, to adopt petitions in support of the Bill, and the Irish Medical Association will send forward its petition in favour next week. The Council of the London College of Surgeons has withdrawn all opposition, and passed unanimously the following resolution:—"That the Medical Act Amendment Bill (1883), as modified and introduced into the House of Commons, meets with the general approval of this Council."

The Scotch Colleges on Tuesday week had a deputation to Mr. Mundella. The delegates were:—Dr. Balfour, Dr. Haldane, and Dr. Wyllie, for the Edinburgh College of Physicians; Dr. Heron Watson, Dr. John Smith, and Dr. John Duncan, from the College of Surgeons, Edinburgh; Dr. Scott-Orr, President, Dr. Eben. Watson, and Dr. D. C. McVail, from the Glasgow Faculty. In the course of the interview it was argued that the Medical Corporations were entitled to six representatives on the Medical Board, whereas the Bill only proposed to give them three, against eight from the Universities. This claim was based upon the ancient foundation and useful character of these institutions. The Universities, it was stated, had always shown a selfish and jealous disposition towards the College, and might still more prejudicially exercise this spirit in the future if allowed the undue preponderance proposed by the Bill to be given to them upon the Medical Board.

Mr. Mundella, without expressing any opinion of his own, said he would represent the views of the deputation to the Lord President when they came to consider any necessary modifications in the details of the Bill. The measure would probably not get into Committee of the House of Commons for several weeks, and it was desirable to make as few changes in it as possible, so as not to delay or imperil the passing of a measure which was so excellent.

The Irish Colleges are also prepared with amendments such as ought not, we think, to be seriously objected to. The College of Physicians wants to have an equal representation on the Irish Medical Board with the other licensing bodies, *i.e.*, three delegates. The College of Surgeons seeks to obtain uniformity of curriculum, and to limit the privilege of a cheap final examination to *bona fide* Arts undergraduates of a University. The College also presses for the admission to the Medical Board of the directly-elected representative, who is—by the Bill—to have a seat only on the Medical Council.

The coming struggle is, in fact, between the Universities and Colleges in Scotland and Ireland. The Universities are seeking to grab all the influence on the Boards and Council, and to introduce clauses into the Bill which will bribe students to resort to them in preference to the Colleges, and they will resist the admission of the direct representative to the Medical Board because they apprehend that he may be a College man, and may dilute the University influence. They wish to handicap the Colleges by compelling Collegiate candidates for the final examination to pay £15 or £20, while the University candidates would have to pay only about £5. Now this proposition is reasonable in the case of the older Universities of Oxford,

Cambridge, and Dublin, which require for their medical degrees a full course of academic study in Arts. In these institutions the student is taught as well as examined, and he has to pay a high price in money and labour before he can obtain his degree, and he is therefore reasonably entitled to a remission of the final fee in consideration of his superior culture, and of the fact that he has not had occasion to avail himself of the museums, libraries, and other means to education maintained by Colleges and Schools. But in the case of the Royal Irish University and some of the Scotch Universities, the case is altogether different. These are not teaching institutions; they receive for examination the students who have been taught elsewhere, and who have learned their business by means of the museums, libraries, and other educational paraphernalia of other institutions, for which advantages it is now claimed that they shall not be asked to pay, simply because they have taken their primary examination in a University instead of a College. Moreover, these Universities exact no education either in Arts or Medicine materially higher than that exacted by the Colleges, for they admit all comers to their degrees on the faith of a preliminary examination not a whit more comprehensive or more stringent than that held by the Colleges. These institutions are Universities in name, but in reality are mere examining centres, and cannot even claim credit as teaching bodies. They are simply touting for the patronage of the student, and they now seek to attract that patronage by securing to themselves the benefit arising from the admission of their students on a cheap final fee.

That privilege may be accorded to their *bona-fide* graduates in Arts, or to undergraduates in Arts of at least three years' standing; but it would be a monstrous injustice to extend these special advantages to students who have not earned them by specially high education, and not paid a shilling more for their instruction than the general run of candidates.

INDIAN MEDICAL SERVICE.

THERE can be little doubt that, while we owe the acquisition of most of our colonial possessions to the success of our arms in the first instance, we are indebted for our subsequent peaceful occupation of them to the successful administration of our non-combatant services, and that foremost amongst these, in the case of our great Indian dependency, is the influence which has been exercised for many years upon every class and caste of the native population by our Indian medical officers. It is equally certain that recent events have not placed us in a position in which we can afford to dispense with any of the props upon which our rule in this country has previously rested. It is upon this ground that we would appeal to the present Secretary of State for India to reconsider the decision arrived at last year by Lord Hartington with reference to the representations made to him by the committee of the "Indian Medical Service Defence Fund" to decline to receive any more such communications, as being neither 'to the advantage of the public service nor conducive to the interests of discipline.' It is impossible to deny that there is deep and widespread discontent among the Indian medical officers, and it is puerile to maintain that it can conduce to the interests of discipline to refuse a

hearing to a respectful exposition of its supposed causes. We will not now enter into the technicalities of "employed and unemployed pay," of stagnant promotion and alleged supersession, of prolonged service in the climate of India, and curtailed pensions; but we can assure the Secretary of State for India that, should he consent to refer the question to a Select Committee, and should the hardships complained of be pronounced frivolous, or insufficient to justify the action taken, the professional press would be the very first to hold up in their true light any body of public servants who, in the hope of grasping temporary personal advantages, would run the risk of bringing discredit upon so valuable a national service as the Indian Medical Department. We therefore have no hesitation in asserting that the true interests of the public service will be best served by exposing the sources of this discontent as illicit and unjustifiable, or rectifying them if just and well grounded, and that this can only be done by a full investigation before an impartial tribunal. Of the results of the present condition of things to the efficiency of the service itself we need not draw any picture; we have too recently seen it all enacted in the ranks of the Army Medical Department during its disruption prior to the granting of the last Warrant, but we would remind those responsible that they have no body of civilian medical men upon whom they can fall back to stop the gap if they allow matters to come to a like pass and wait "in the interests of discipline" till candidates refuse to compete for the appointments.

DR. CARPENTER AND ANTI-VACCINATION.

ANTI-VACCINATORS cannot fail to be much exercised in spirit over the cruel disappointment suffered by their hopes on the evening which was fondly expected by many of them to yield a harvest of success for "the cause." Mr. Hopwood, as their champion in the House of Commons, was to have challenged an expression of legislative opinion on the necessity for considering whether the time had not arrived for conferring as much freedom on British subjects to disseminate small-pox as has been extended to them in respect to syphilis. Circumstances, however, over which anti-vaccinators could exercise no control, have, fortunately for civilisation, for a time deferred the realisation of the dreams indulged in by the "League" presided over by Mr. P. A. Taylor, and upheld by his followers. But that the present is a critical period in the history of vaccination controversy, and of the warfare against science and common sense carried on by the fanatical bands of agitators against compulsory preservation of life, there is no question; and it is gratifying, therefore, to find that, while every description of tactic is being resorted to by the paid agents of anti-vaccination to swell the lists of apparent objectors to the Acts, such an able exponent of the fallacies they indulge in as Dr. W. B. Carpenter is watchfully busy in refuting the arguments used to bolster up "the League's" defences.

In a letter addressed to Sir Lyon Playfair, Dr. Carpenter deals Mr. P. A. Taylor what is probably the cruellest blow he has yet received, inasmuch as it utterly demolishes the beautiful theory so laboriously and triumphantly built up on the basis of statistics. From

information afforded by a table quoted in one of Mr. Taylor's own anti-vaccination essays, Dr. Carpenter shows that the small-pox death-rate has progressively declined since the introduction of compulsory vaccination; and this, too, in most striking fashion, particularly in Scotland, where the good sense of the people is proof against the frenzied enthusiasm of would be reactionists, and where a reduction of no less than *eighty-eight* per cent. of deaths due to variola occurred within five years after neglect of vaccination was made a punishable offence against the law.

There is often a good deal of astonishment felt by reasonable men at the wooden obstinacy with which the "thick and thin" advocates of infection refuse to perceive the force of facts. But when we are called upon to deal with the utterances of those who cannot excuse their words and actions on the plea of ignorance, amazement at the obtuseness of the less educated adherents of a defenceless cause gives place to a feeling of regret at the persistence with which mistaken views are clung to. It is not possible to assume that Mr. Taylor can be blind to the irresistible logic of such statements as Dr. Carpenter showers down upon him, each and all conclusively demonstrative of the absolute danger to public health arising from non-compliance with the Vaccination Acts. Thus, in the year 1881, the date of the last epidemic in this country, Dr. Carpenter states:—"Of the 2,375 recorded deaths (from small-pox) 962 occurred among the certified *unvaccinated*, and 524 among the certified *vaccinated*, 885 being reported as 'doubtful.' It is quite evident that, even if the unvaccinated residuum be admitted to constitute 15 per cent. of the metropolitan population, the advantage is enormously on the side of the vaccinated, for (putting aside the 'doubtful' cases), if the vaccinated portion of the population of London had died at the same rate as the unvaccinated, *their* mortality would have been 5,451, or more than ten times as great as it actually was." Doubtless an answer to Dr. Carpenter's conclusions will speedily issue either from Mr. Taylor or one of his staff of essayists, and attempts will be made to explain away the overwhelming truths contained in the pamphlet. One more passage from it we will quote in this connection:—"If vaccination affords no protection, the *ages* at which the vaccinated and the unvaccinated respectively die should correspond; but the *exact reverse* of this is shown to be the fact by the Registrar-General's latest figures, as by all previous comparisons. Of the 962 deaths among the unvaccinated, *three-fourths* (speaking roughly) occurred *under* the age of 20, the disease showing the same fatality among the young at present that it used to do in pre-vaccination times: but of the 524 deaths among the vaccinated, *three-fourths* occurred *above* the age of 20—that is to say, among *adults*, who had outgrown their original protection, and had not (so far as was ascertained) renewed it by revaccination. The proportion of children under 5 years old, vaccinated however indifferently, that died in the epidemic of 1881 was quite insignificant, being only 5.2 per cent. of the 524 deaths among the vaccinated; whilst the proportion of deaths among *unvaccinated* children under 5 years of age was 38.2 per cent. of the 962 deaths in that class."

Without any further following Dr. Carpenter in the carefully-reasoned and fact-sustained statements he advances to show cause why support should not be given to the demand for repeal of the Vaccination Acts, the letter from which the above-quoted passages are taken may be earnestly recommended to the perusal of all who can and will read truth and appreciate it for themselves.

For a long time the mode of warfare pursued by anti-vaccinating societies has called forth indignant protests from persons who are naturally scandalised by the contemptible tactics which seem to be justified by those who ask for subscriptions to carry on "the work." One mode of "working" which commends itself to "The London Society for the Abolition of Compulsory Vaccination" has recently come under our notice. It is as follows:—Armed with an almost inexhaustible supply of coloured handbills, headed "Medical Opinion concerning the Perils of Vaccination," an agent of the Society makes a raid on one of the blocks of industrial dwellings now so numerous in the metropolis. The hour chosen (wisely) is one during which the male population is away, and then the bills are distributed from house to house, the while the agent insidiously points to displayed sentences in the delectable trash he is giving away—such as "Healthy up to the hour of vaccination," "Abominable fouling of the human body," "Dismal results of vaccination," &c., &c.; and the mothers of children having been duly stuffed with this nauseous mixture, are solicited, and often enough consent, to sign a petition "against killing children in such frightful ways." This may be a mode of proceeding which commends itself to anti-vaccinators; to us it savours strongly of the most unblushing imposture; and what value can attach to petitions so signed may well be queried; while the ease with which the names of terrified mothers, ignorant even of the meaning involved by the terms they hear and read, can be obtained, may be at once imagined.

The particular document to which we have referred is in itself a curiosity of the first order; and we doubt not Mr. Bruce Clarke, M.B., F.R.C.S., will be interested to learn that it classes him amongst medical opponents of vaccination, an extract from a paper contributed by him to *St. Bartholomew's Hospital Reports*, attractively headed for anti-vaccination purposes "And the Child Died," forming an important section of the handbill. We are bound, nevertheless, to admire the catholicity exhibited by the selection of names made by the "London Society, &c., &c.;" and Mr. Clarke can also congratulate himself on association with, at any rate, well-advertised practitioners, for we note among the "authorities" Dr. Forbes Laurie, whom we last heard of in connection with a magnetic invention for the cure of piles and hernia. As Dr. Laurie's "testimony" includes incidental reference to another "authority" "who was 17 years engaged in the Isle of Wight in *curing cancer*," it may be concluded that his association of this disease with compulsory vaccination is another indication of that vast experience and knowledge of physical medicine so characteristic of "the Society, &c." While, however, we involuntarily pity Mr. Bruce Clarke's unhappy

position, we are unable to suggest how, so long as fanaticism and ignorance find that it pays to act in concert, honourable and scientific medical men are to avoid such indignities being thrust upon them.

Notes on Current Topics.

The New Law Courts.

THE precipitate haste which characterised the arrangements made for transaction of legal business within the new palace of justice is beginning to bear such fruit as should have been anticipated from hurried occupancy of a building which still retained the features of a new erection. From the moment of its first inauguration as a public institution the new Law Courts has been a ceaseless cause of physical inconvenience to many whose duties compel them to be constantly within its walls. The most incautious householder is usually chary of taking permanent possession of a new residence, until such time has passed subsequent to its completion as may suffice to dry the structure, at least moderately well. At the Law Courts, however, where, especially, much time and care would be required to thoroughly dry the massive walls composing it, there has been almost no attention, in the way of pause, paid to this first condition of hygienic importance to those destined to suffer whatever inconvenience may arise from the omission. The consequence is that cases of illness among officials engaged at the Courts are so frequent, and so evidently due to the nature of their surroundings, that these public servants are very naturally much exercised in mind over the affair, and are said to be about to present a memorial to the Treasury, praying that the Law Courts may be scheduled as an "unhealthy place." The effect of this action, if pursued, will be to entitle all who serve in the Courts to special additional pensions, granted in recognition of the increased dangers incurred through unhealthy surroundings. There is nothing in the memorial of an extravagant nature, moreover, a period of three years being the time named as that which is considered necessary to afford such experience as will suffice to show the various alterations needed to overcome existing defects, and also to dry the walls, in which, at the present time, a very great degree of moisture undoubtedly remains.

Sir Charles Dilke on the Proposed New Consolidated Order.

THERE is a Birmingham caucus which is said largely to influence Government policy in the present Liberal administration. As independent journalists, however, politics have to us no meaning, but we cannot help remarking that it was to a Birmingham deputation Sir Charles Dilke addressed the words of hope, "that the dismissal of Poor-law officers would soon be placed in the hands of Poor-law guardians throughout the country." The Poor-law medical officers throughout the country must have read these words with regret and surprise. Fixity of tenure had been secured by a legitimate agitation. Dismissal by the Local Government Board added to this meant security against injustice and malice. It would be a destructive policy on the part of the present Government to undo the work of their predecessors. In

the face of what they have done in reference to the Contagious Diseases Act, can we hope for much grace at their hands? We can if we are able to apply pressure so as to counteract the influences at work which have brought about the proposed consolidated order.

The Poor-law medical officers throughout the country ought to have some influence; they should now take action singly, whilst, at the same time, they should come forward and support the Poor-law Medical Officers' Association. Singly they should work in their own districts, and as a united body they should appeal to Parliament against the contemplated order. We shall be glad to aid them in the struggle, but we regret to have to state that the profession is frequently apathetic to its own interests, and it is in consequence of this that it suffers so many wrongs, and the Poor-law medical officers will be justly punished if they do not now rise to the occasion and protest in an emphatic manner against the injustice about to be perpetrated upon them.

The Fisheries Exhibition.

ON Saturday last an event of very considerable importance to the whole community occurred at the Royal Horticultural Society's Buildings, South Kensington, when, with much pomp and magnificence, and in the presence of many thousands of spectators, the Prince of Wales, in the name of Her Majesty, opened the Fisheries Exhibition to the public. The exhibition, which has been many months in preparation, is most probably destined to initiate a very remarkable change in fish supply and fish consumption in this country. It will not only tend to awaken universal interest in natural and artificial pisciculture, in the nature and products of the various fisheries, and in the general magnitude and importance of fishing and fishers, but it will, if the best wishes of its promoters are realised, be the means of bringing home to the intelligence of the people the great fact that the sea is a practically inexhaustible source of supply of cheap, wholesome, and nutritious food. As a means to this end, visitors to the exhibition will be able to indulge in regular "fish dinners" at a reasonable charge; and many to whom the delicacy of fresh fish well cooked is all but unknown may be expected to return from visiting the exhibition endowed with a wish to test by further experience the advantages of a diet which has so much to recommend it. Of the wonders of the mighty collection it is impossible to speak in a note; but it may be said that much surprise will be felt by a good many persons who first notice on going through the collection how multitudinous are the associations of fishing with other arts and sciences. The six months during which the exhibition is to remain open will be scarcely more than enough to enable a diligent student to make a careful survey of all that there is for him to see and examine.

FROM a report furnished by M. Béclard, Dean of the Medical "Faculté" at Paris, to the Vice Rector there, it appears that the number of women following the profession as regular students, *i.e.*, those who have produced two diplomas, of bachelor of letters and science, or if foreigners, certificates equivalent thereto, is 39 during the past two years—10 French, 11 English, 5 American, 9 Russian, 1 Hungarian, 1 Polish, 1 Roumanian, 1 Indian.

Medical Fees in English Law Courts.

THE question may be fairly asked why the fee of one guinea is considered a sufficient remuneration to medical witnesses who are summoned to attend in criminal cases at the Assizes? For this sum the medical man is withdrawn from his professional pursuits, no matter what his status or income; he has to neglect his patients, with the possible chance of losing them, and to put up with the annoyance, trouble, and loss inevitably entailed for this niggardly fee. No wonder that practitioners of reputation shirk criminal cases, and whenever possible transfer the questionable honour to the young and necessarily inexperienced. We are aware that justice does not gain by this; but is it reasonable to expect medical men to do what no other profession would condescend to, when not in the cause of charity. Our gratuitous work is extensive enough as it is, without trespassing too severely upon our philanthropy. Even our considerations of duty must necessarily have a limit, and we make bold to assert that most medical men draw the line at police cases. If occasionally there be a failure of justice from this cause, the responsibility rests upon those who have fixed the fee at a guinea. Three guineas a day would hardly be considered excessive for attendance at the Assizes in criminal cases.

The Minutes of the Medical Council.

THE complete volume of the minutes of the meeting which was held last week was issued on April 30 with praiseworthy celerity. It contains also the record of the proceedings of the Executive Committee and of the English Branch Council, and is in the hands of the public much sooner than has heretofore been usual. An item of special interest in the volume is the report by Dr. T. King Chambers on unqualified assistants, which is now appearing *seriatim* in another part of this journal.

The Registrar-General's Annual Summary.

IN the Annual Summary for 1882, just issued by the Registrar-General, in respect to London and other great towns, the number of large towns included in the list of weekly variations has been raised, in accordance with the change made in the beginning of the year, from twenty to twenty-eight. The additional towns are Derby, Birkenhead, Bolton, Blackburn, Preston, Huddersfield, Halifax, and Cardiff. The population dealt with in this return is 9,466,292, or more than one-third of the total for England and Wales. In this population the deaths reached to 205,235, or 21·8 per 1,000, Derby being lowest, with a rate of 18·7, and Preston highest with 27·6 per 1,000; London and Brighton were 21·4 and 21·7 respectively. It is interesting to know that with the exception of the years 1850 (21·0) and 1881 (21·2) the death-rate for last year is the lowest recorded, that for 1872 having exactly equalled it. Of the whole number of deaths 16·3 per cent. or 13,553 were registered as due to zymotic diseases, the aggregate rate thus reaching 3·49 per 1,000. As recorded in the report, the most remarkable fact in this connection was the subsidence of the small-pox outbreak. In 1881, 2,367 deaths took place from this disease, in 1882 only 431. Of these 431 persons who died, 108 were certified to have been vaccinated, 184

unvaccinated, while 139 were doubtful. These figures, therefore, show that, while the deaths among vaccinated persons were 37·0 per cent., of the unvaccinated 63·0 per cent. died. Another curious point in connection with the same figures is that of the vaccinated 23 per cent. were under 20, and 77 per cent. over 20 years of age; while among the unvaccinated the proportions were nearly reversed, viz., 67·4 and 39·6 per cent. respectively.

Venereal Disease among our Troops in Egypt.

MR. WARTON asked, last week, in the House of Commons, whether, lately, at Cairo, in one battalion about 650 strong, 75 men were laid up at one time in consequence of venereal disease.—The Marquis of Hartington replied that on April 13 the soldiers of the force at Cairo under treatment for venereal disease amounted to 2·65 of the strength, which would give an average of only about 17 for a battalion of 650 men. By a later return, received May 3, it appeared that of the whole force in Egypt about 3½ per cent. were in hospital for venereal disease.

The Adelaide Hospital.

At a meeting of the Medical Board of the Adelaide Hospital, Dublin, held on Friday, the 11th inst., H. Head, Esq., M.D., in the chair, the following resolution was unanimously adopted:—Resolved, "That the Medical Board of the Adelaide Hospital desire to record their deep regret at the death of Mr. B. Wills Richardson, who has been a valued member of the staff of this institution since its recognition as a clinical hospital. His strictly punctual and conscientious attention to his duties, his honourable conduct, and his uniform regard for the interest and reputation of his colleagues, caused Mr. Richardson to occupy the highest place in the regard of the members of the medical staff. They ever reposed the most perfect confidence in his honour, and cannot but feel that his death will be an almost irreparable loss to them and to the poor, in the treatment of whom he never spared time or trouble, and they wish to convey to Mrs. Richardson and the family their sincere sympathies in their bereavement."

Fissured Anus.

DR. THOMAS HAY, of Philadelphia, speaks highly of the value of iodoform in the treatment of this troublesome complaint. It may be applied either as a powder pure, or mixed with gum acacia; as an ointment, mixed with vaseline; or as a suppository, made with the oil of theobroma. The intensity of the iodoform odour may be moderated by balsam of Peru, carbolic acid, and oil of peppermint; but are not likely to be required for application to such a part. Care must be taken to reduce the iodoform crystals thoroughly to powder, otherwise great irritation may be induced. Applications should be made three or four times a day. The bowels should never be allowed to become constipated or relaxed; the alvine secretions should be always maintained in a soft condition. The anus and surrounding parts should be kept scrupulously clean. The great point to remember is to have the powder properly prepared and *very fine*.

Another Medical Act Amendment Bill.

A BILL was introduced last week into the Lords by Lord O'Hagan to make provision for the election of a representative of the Royal Irish University in the General Medical Council. The necessity for such a measure arose from the omission in the Royal Irish University Act to provide for the continuance in office of the Queen's University representative—Dr. Banks—as representative of the Royal Irish University, in consequence of which lapse Dr. Banks was entitled to his seat at the Medical Council only for the unexpired portion of his period of appointment. To remedy his difficulty a Bill was last year passed through the House of Commons; but—from some mistake or hindrance—it never went up to the Lords, and, of course, fell through. By this, Dr. Banks was unable to take his seat at the recent meeting of the Medical Council, his period of appointment having lapsed in the interval; and he is not now entitled to act as a member of the Irish Branch Council. We presume that Lord O'Hagan's Bill will go through both Houses unopposed immediately after the Whitsuntide recess—unless, indeed, Mr. Warton or Mr. Biggar, the rival bill-blockers, add to their high repute as legislators by putting a stop on this innocent and necessary measure.

Three Cases of Cæsarian Section.

THIS formidable operation has quite recently been performed three times by Professor C. Braun, of Vienna.

The first case was that of a woman the possessor of a rickety pelvis. She had never borne a child. The operation was carried out without difficulty. Two days afterwards the patient was free from both pain and fever. The second was that of a dwarf cretin. In this case some delay was caused by the protrusion of coils of intestine from the abdominal wound. On the following day the temperature was 38.4° C., and as the patient was an idiot, which of course interfered with the proper subsequent treatment, the prognosis was somewhat unfavourable. The third patient was the subject of osteomalacia. She had previously given birth to two children, which were extracted manually. In this case, at the date of report, the prognosis was favourable. In all the cases Porro's modification of the operation was the one carried out. These reports, which are from the *Wien. Med. Zeitung*, Nos. 18 and 19, 1883, lose much of their value by the omission of the results to the mother. The child in the first and last cases was extracted alive, but in the second it was dead in consequence of its inspiration of liquor amnii.

THE annual *convention* of the Pharmaceutical Society of Great Britain has been fixed for Wednesday, May 23rd, when the whole of the buildings of the South Kensington Museum will be thrown open for the occasion.

THE Sanitary Assurance Association have, on the motion of Mr. W. White, F.R.S., seconded by Dr. Norman Chevers, resolved on further legislation, compelling the builders of all new dwellings to obtain a certificate from some authority or qualified person as to their sanitary condition before it shall be lawful for such buildings to be inhabited.

Almost a Centenarian.

LAST week there died at Newbury, Berkshire, a member of the profession who had nearly reached the patriarchal age of a hundred years, in the person of Mr. Richard Rodd Robinson. Deceased was in early life an army surgeon, and was on the medical staff at the battle of Waterloo, and served in all the campaigns of the sanguinary period. He became a Member of the Royal College of Surgeons in 1810, and was, we believe, until a few days ago, the oldest living member of that College.

THE annual dinner of the officers of the Army Medical Department will take place on Friday, 25th of May, 1883, at the Inns of Court Hotel, London.

AT a congregation of the University of Cambridge, to be held on June 13, it is proposed to confer the honorary degree of LL.D. upon M. Louis Pasteur, Member of the French Academy, Director of the Ecole Normale, Paris.

THE Secretary of the Parkes Museum of Hygiene informs us that Her Majesty the Queen has written a congratulatory letter on the satisfactory progress of this institution, raised to the memory of our illustrious *confère*.

THE Dublin University Biological Association will hold its concluding meeting on Thursday next, the 17th inst., in the Museum Buildings of Trinity College, when an address on "The Collective Investigation of Disease" will be delivered by Dr. Finny.

THE Medical Board of Adelaide Hospital, Dublin, will proceed, on the 8th of June, to elect a successor to the late Mr. B. Wills Richardson, whose lamented death has caused a vacancy on the surgical staff of the hospital. Applications should be forwarded to the honorary secretary of the Medical Board not later than Friday, 1st of June.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their populations, were—Bradford, Brighton, Portsmouth, Derby 15; Edinburgh 16; Halifax 17; Leicester, Plymouth 18; Cardiff, London 19; Bristol, Birkenhead 20; Birmingham, Salford 21; Norwich, Wolverhampton, Newcastle-on-Tyne, Bolton 22; Blackburn, Nottingham, Preston 23; Huddersfield 24; Oldham, Leeds, Sunderland 25; Liverpool 26; Manchester, Sheffield 29; Hall, Glasgow 31; Dublin 34.

THE mortality last week in the large towns from diseases of the zymotic class was exceedingly light; in some towns no deaths were reported under this head; and the highest death-rates from whooping-cough were 1.5 in Hull, and 2.9 in Cardiff; from measles, 1.2 in Sheffield; from scarlet fever, 1.9 in Leeds, and 3.4 in Sheffield; and from "fever," 1.6 in Portsmouth, and 2.2 in Sunderland. The 24 deaths from diphtheria included 16 in London, 2 in Glasgow, and 2 in Liverpool. Small-pox caused 2 deaths in London, 2 in Birmingham, one in Liverpool, and one in Cardiff.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 24, Bombay 34, Paris 28, Geneva 30, Brussels 31, Amsterdam 25, Rotterdam 25, The Hague 26, Copenhagen 29, Stockholm 24, Christiania 15, St. Petersburg 40, Berlin 27, Hamburg 25, Dresden 26, Breslau 28, Munich 36, Vienna 37, Prague 41, Buda-Pesth 35, Trieste 27, Rome 35, Turin 25, Venice 28, Lisbon 27, New York 29, Brooklyn 22, Philadelphia 24, Baltimore 21.

THE Professorship of Anatomy in the University of Cambridge has become vacant by the resignation of Professor Humphry. Dr. Humphry will not, however, cease to be a Professor in the University. It is intended to establish a Professorship of Surgery, to which Dr. Humphry will be elected; and he has generously offered to discharge the duties without a stipend until the income of the University will permit the proper endowment of the chair. We understand that Dr. MacAlister, the distinguished Professor of Anatomy in the Dublin University School of Physic, will be a candidate for the Chair of Anatomy vacated by Professor Humphry.

IN our report of the proceedings of the General Medical Council it is stated that the record of Dr. Robert Gray's (Armagh) qualification as Licentiate of the King and Queen's College of Physicians in Ireland was erased from the Medical Register at the instance of the College. In justice to Mr. Gray it is right to explain that this erasure was effected not at all in consequence of his having incurred the censure of the College, but simply because the dispensing of prescriptions for the general public, which is part of Mr. Gray's business, is incompatible with the declaration which he took when he received his licence from the College. He, therefore, felt called upon to return his diploma to the College, and, as a matter of course, he was struck off the roll of Licentiates both by the College and the Medical Council.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

MR. WILLIAM McEWEN AND THE ROYAL INFIRMARY, GLASGOW.—In consequence of the recent decision of the Directors of the Glasgow Royal Infirmary on the chloroform question, Mr. Wm. McEwen has withdrawn his resignation as Chairman of the House Committee.

THE REGISTRAR-GENERAL'S RETURN.—From the official returns in the eight principal towns of Scotland for the week ending Saturday, May 5, the death-rate is estimated at 25.0 per 1,000 of population. This rate is 1.3 above that for the corresponding week of last year, but 2.6 below that for the previous week of the present year. The lowest mortality was recorded in Perth—viz., 15.3 per 1,000; and the highest in Paisley—viz., 35.3 per 1,000. The mortality from the seven most familiar zymotic diseases was at the rate of 3.8 per 1,000, or 0.6 below the rate for the previous week. Measles was the most fatal miasmatic disease, the mortality therefrom being greatest in Glasgow. From acute diseases of the chest 132 deaths were registered, or 13 more than in the previous week.

GREENOCK.—DEATH OF DR. JOHN MACCULLOCH.—A telegram has been received in Greenock which announces the death at Otago, New Zealand, of Dr. John MacCulloch, the last surviving son of the late Rev. Dr. J. M. MacCulloch, of the West Parish, Greenock. Deceased, who was about forty years of age, was, for a considerable time previous to his sailing for New Zealand, in delicate health, and it was thought that the voyage might prove beneficial, but unfortunately this has not been the case. He leaves a widow, but no family.

STUDENTS' GRIEVANCES IN THE SCOTTISH UNIVERSITIES.—There is a very general feeling among the profession in the great seats of medical education in Scotland that the evident bias shown by Mr. Mundella in favour of the Universities before the recent deputation of the corporations and extra-mural teachers is based on a misconception of the true state of affairs. On the part of the students and of their parents, who should have some consideration shown them, we propose to state a few facts as clearly as possible. Anyone taking up the calendar of the University of Edinburgh will find a table giving the cost for obtaining the degrees of M.B., C.M., to be £107 18s., spread over four years. He will also find that one course of lectures in each branch of study is alone required. But what are the facts of the case? To be very plain we will take the student through the curriculum. Beginning in winter, he attends classes on chemistry, anatomy, and practical anatomy; during the summer on botany and natural history, and practical chemistry. During the second winter on physiology and surgery, at the end of which he may go up for his examination in chemistry, botany, and natural history. It will be noticed here that all the subjects for the first examination have been attended before the beginning of the second winter, but the regulations are so worded that "attendance on at least two classes during each of two summer sessions and one winter session" is required. To perform this feat the unfortunate student who begins in summer is obliged to take botany or natural history over twice, subjects which cannot be said to be of vital importance to the student. But further, during his second summer he attends practical materia medica, and during his third winter materia medica, pathology, and clinical surgery. Then comes the examination in anatomy, physiology, pathology, and materia medica. Anatomy, it will be remembered, is attended during the first winter, and physiology during the second. This refined arrangement necessitates two, if not three, courses of anatomy, and students have been known to pay the professor £20 for this subject instead of £7 7s., as stated in the calendar. This leaves the student one summer and a winter for jurisprudence, practice of medicine, midwifery, and clinical medicine. The real practical work of the profession condensed into eight months! The examination in botany, chemistry, and natural history could well be taken at the end of the first summer, and the subjects for the second at the end of the second winter, but this would not please the professors of botany and natural history, who get a second fee from those students beginning in summer, or the professor of anatomy, who looks forward to two, if not three, courses of anatomy and for the accompanying fees. In Edinburgh, where the extra-mural lecturers on anatomy are very strong, the professor of course feels the pinch of the extra-mural school, but being an examiner he frequently gets a fee, even from medallists in the extra-mural school, who admit that one must "kiss the son, lest he be angry." But there is another cause for complaint. The professors of pathology, physiology, materia medica, natural history, and botany have invented practical classes, with, of course, an extra fee. These classes are not required by the University, but are very

excellent means by which students are compelled to pay, for professors have been known to frequently put this question as a preliminary test of knowledge—"Have you attended my practical class?" "No!" is the reply. "It would have been better for yourself if you had done so." This, says our contemporary the *Scotsman*, "may be a simple truism coming from the professor; but when it is followed by plucking it has another look." Surely when a professor engages to teach physiology or pathology, he ought to teach it both theoretically and practically for one and the same fee. And again, when a student inquires of his professor what text-book he shall read, he is blandly informed—My book or syllabus; and if the professor has not been to the trouble of compiling one or other of these, there comes the answer—Take notes of my lectures. It is stated that there is only one professor in the University who informs students that his lectures are not sufficient, and that they must read the text-books he prescribed. It is to be hoped that, with these facts before them, those engaged in present legislation will take care that justice be fairly administered.

UNIVERSITY OF EDINBURGH.—LECTURESHIP ON OPHTHALMOLOGY.—Dr. Argyll Robertson, who was recently appointed lecturer in ophthalmology in the University of Edinburgh, delivered his opening lecture within the University on Monday, the 7th inst. Dr. Robertson said that that being the first special course on eye diseases delivered in their ancient University, rendered it more than usually imperative upon him to explain the conditions which had rendered the institution of such a course of lectures desirable. Hitherto diseases of the eye had formed a part of the ordinary systematic course of the Professor of Surgery, and a few lectures had with difficulty been set apart from his very much overburdened course to their consideration. But in consequence of the recent advances in diagnosis, the bounds of ophthalmological surgery had become enormously extended; and the University authorities, recognising the urgent necessity of affording efficient instruction in diseases of the eye, and the impossibility of the Professor of Surgery treating them in a manner adequate to their importance, had decided on instituting this course. Having glanced at the process of sub-division which had gone on in recent times in the different branches of knowledge and in their teaching, he considered the arguments for and against specialism and specialists in medical and surgical science and practice. Whilst condemning a narrow and exclusive specialism, he advocated the study and pursuit of a special branch of the profession by men who were careful to follow the general advance of medical science and to appreciate the bearing of this upon their speciality.

ABERDEEN UNIVERSITY.—OPENING OF SUMMER SESSION.—The summer session for medical students was opened at Marischal College, Aberdeen, on Monday, the 7th inst., and will extend over a period of three months. Before proceeding with the work of the anatomy class, Professor Struthers delivered an address, bringing under notice the additional courses of instruction which were now placed within reach of Aberdeen students. These included lectures on insanity, public health, diseases of the ear and larynx, and diseases of the skin. The great addition which had been made to the strength of the school, however, had been in pathological anatomy by the institution of a professorship through the munificence of Sir Erasmus Wilson, and he warmly congratulated the students on having the opportunity of so usefully occupying part of the day in the summer session of their third year by attending the practical class conducted by Dr. Hamilton in his pathological laboratory. Referring

to the position of medical schools generally, Dr. Struthers said that for years back Aberdeen had been in no way behind any school in its scientific tone, and that it had, over all schools known to him, the advantage of thorough practical teaching. The former weakness in the fourth year had been very largely rectified by the institution of a pathological department. In this respect, indeed, Aberdeen stood out alone among all British schools of medicine, and took rank with the Universities of Germany.

THE CHLOROFORM QUESTION AT THE GLASGOW ROYAL INFIRMARY.—The unfortunate dispute on the chloroform question at the Glasgow Royal Infirmary promises to terminate shortly on the following basis:—At a meeting of the managers, held on the 7th inst., the special committee to which this matter was remitted presented the following report: "1. When a surgeon receives a new assistant, he will instruct him practically in the manner of giving anæsthetics, and in the dangers to be guarded against in the administration thereof, as well as in the best method of combating these dangers when they arise; and the course of clinical instruction given by the surgeons shall include demonstrations on the practical administration of anæsthetics. 2. In appointing the assistants, the managers will consider it of importance that the candidates shall have received special instruction on the action of anæsthetics, or have a certificate showing that they have a proper knowledge of the subject. 3. When a surgeon is satisfied of his assistant's knowledge of the subjects mentioned in Rule 1, he shall grant to him a certificate to that effect, which the assistant shall present to the superintendent. 4. The assistants shall not be entitled to perform any operation under an anæsthetic in the absence of the visiting physician or surgeon unless they are legally qualified, and unless they have previously obtained and presented a certificate, as above provided, and then only in the presence of one of the dispensary staff, whom failing, the superintendent, and of one other assistant qualified as above provided. 5. In cases of extreme urgency occurring in the absence of the surgeon, and when neither the superintendent nor any of the dispensary staff are in the hospital, any qualified assistant, with the aid of another qualified assistant, may do what appears necessary until the arrival of the surgeon or superintendent, or one of the dispensary staff. 6. In the absence of the physician or surgeon, the superintendent shall exercise a general control over the assistants in the admission and treatment of patients under their charge, it being understood, however, that he is not to interfere with the treatment ordered by the physician or surgeon. 7. All cases of administration of anæsthetics in the surgeon's absence must be forthwith entered in the Operation Book, and reported to him at his next visit. 8. In case of a death occurring while the patient is under an anæsthetic, whether in the presence or absence of the physician or surgeon, he shall make particular note of all the circumstances of the case in the Ward Journal or Operation Book, and shall report the same, through the superintendent, to the next meeting of the weekly committee.

Correspondence.

DUBLIN HOSPITALS AND THE IRISH PROFESSION. TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—We are always saying that there is no profession so defrauded as ours, and yet we every day assist in defrauding one another. What is the use of talk without action? Silence would be more dignified than old womanly grumbings. I have, however, a hope that there is a growing awakening as to the absolute necessity for substituting deeds for mere words, and co-operation and energetic action for isolated and barren

protests. Here, now, are two instances where the profession has been wronged. Within the last two weeks two wealthy females who had arranged to be operated on by me for tumours at the Mater Misericordiae Hospital, Dublin, in order that they might be operated on for nothing, thus obtaining the services of our profession gratuitously, and at the same time depriving two poor persons of those beds which were designed for them and for none other. I notified the facts to one of the staff of the Mater, and called on them in their own interests quite as much as mine to insist on the removal of the parties to lodgings, so as to charge them proper fees or to send them home. That letter led to no action and I now bring the matter under the cognizance of the Irish profession at large, and I would remind them that it is not because these cases are samples, not exceptions, and that these acts of injustice are of long standing, are practised by every hospital in Dublin, and embrace within their wide sphere every doctor in Ireland, that therefore it is hopeless to attempt to deal with them, and that we provincials must continue to lie under the wrong and the loss. I tell my provincial brethren that if they only but will it, they can put down, and put down thoroughly and promptly and decisively this grievous injustice to themselves. I know that many provincial doctors do not care to operate, and that many of these, misled by a short-sighted jealousy, very often prefer to smuggle even wealthy patients into Dublin hospitals. I would meet such local jealousies by having the consultant allow the local man to operate where the latter brings him in; and where he is willing to operate and where he is not willing I would have his presence invariably sought as of right, and I think that such a course as this would go far to get rid of the provincial help at present given to the injurious system complained of. I will undertake to propound a practical proposal, and would invite as many provincial men as possible to form a society for meeting the action of those Dublin physicians and surgeons who would persist in keeping wealthy patients, whether medical or surgical, in hospital after having been informed of the means of the parties. One of us should be charged to report every improper case to the senior surgeon or physician of the hospital into which such parties might smuggle themselves, and to duly advertise the medical public on the action taken thereon by the different hospital staffs. In this matter medical students could render important service, and looking at the fact that it will be their interest to-morrow, as it is ours to-day, to stamp this practice out, I cannot permit myself to doubt that they will be found so wanting in shrewdness as to hesitate to give every assistance in their power. Let every offending Dublin hospital be convinced that there is at least a large body of provincials who are thoroughly in earnest, and we shall make an end of one of the most grievous systems of injustice that our profession has now to complain of. Once again let me appeal to my brethren to wake up to some kind of perception of the pecuniary loss which they sustain, and to the fact that it is in their power to make an end to such losses. It is not operation cases alone that are smuggled into Dublin hospitals, but wealthy medical cases are daily admitted into them also. There is not the slightest use, I fear, for one individual to appeal to the metropolitan staffs. They have been ere now appealed to again and again, and always in vain.

Yours truly,

Cashel, April 20, 1882.

THOMAS LAFFAN.

THE PREVENTION OF CONFLAGRATIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your paper of May 9th, page 412, you refer to the precautions taken by the committee of the Royal College of Physicians to prevent the destruction of their fine library by fire. To my mind, however, the steps decided upon appear likely to be equally destructive as fire itself, because the agent intended to combat with the fire is water.

A very simple and inexpensive plan, devised by myself, will so flood a room or building with carbonic acid that combustion is impossible, and things could be so arranged that a child could start the carbonic acid stream, and a small gas engine, brought into action in a few minutes, could exhaust, by means of a fan, the ordinary atmosphere of the building, so allowing instantaneous entrance of the gas. By the systematic series of pipes necessary for the extinction of fire, the air of any building could be purified by aid of the

“chemical lung.” This system is equally applicable to theatres, warehouses, and any other structures, any of which can be kept flooded with chemically pure air, however crowded, or rendered absolutely indestructible by any flames. I have begged to be allowed to lay my scheme in detail before the committee.

Yours obediently,

RICHARD NEALE, M.D. Lond.

60 Boundary Road, South Hampstead,
May 16th.

Medico-Parliamentary.

HOUSE OF LORDS.—THURSDAY, MAY 10TH.

THE CONTAGIOUS DISEASES ACTS.

LORD ORANMORE and BROWNE inquired whether orders had been given to the police not to enforce the Contagious Diseases Acts at Chatham and other places, and, if so, on what grounds the Government had discontinued to enforce an Act of Parliament?

The Earl of NORTHBROOK replied that the House of Commons had decided, by a considerable majority, against compulsory examination. Under these circumstances, it had been considered undesirable to any longer employ in this connection the metropolitan police, for whose employment there was no obligation in the Acts. It had also been decided to introduce later in the session a Bill modifying these Acts, retaining those portions relating to voluntary submission to examination, and leaving out the compulsory powers.

The Earl of HARDWICKE remarked that, owing to the backward state of public business, it was improbable that any Bill such as that just referred to would pass this session. Did the Government intend to surrender their powers into the hands of a body of gentlemen who, though actuated by high motives, were bitterly opposed to one of the most beneficial and charitable measures ever adopted by a Legislature? These Acts had operated with the utmost benefit to all parties. The Government had given way to a popular outcry, and this ought to be resisted by their lordships. It was their bounden duty to express a stern and decided opinion on the action of Her Majesty's Government on this subject—in fact, he doubted the legality of their action. The House of Commons had not refused the money, and the matter might have been brought up on the vote, and discussed, instead of being decided by a snatch vote and a haphazard division. He trusted the Government would consider further their proposition with regard to the annulment of these Acts of Parliament.

The Duke of CAMBRIDGE wished to say one or two words upon this subject. He had no hesitation in saying that the Acts of Parliament had been of very great benefit wherever they had been put in operation, and those places would be the last to ask for their repeal. That being so, he thought that the question should be more fully considered by the Government. No doubt the question was a difficult one, seeing what had been done in another place, but he would ask their lordships not to agree to the sweeping away of these Acts, and, consequently, of all the good which they had done, because of the vote which was come to in the House of Commons. If the Acts had done good only to the two services, and not to the whole of the community at large, he would not say one word in their favour, but he believed that they had been most beneficial in their operation, not only to the two services, but to many others, as there could be no doubt that since they were passed there had been a great decrease of immorality in the garrison towns and seaports (hear).

The LORD CHANCELLOR did not rise to say one word on the question of the policy of the Acts, or of the alteration in regard to them in consequence of the vote in the House of Commons. But as the noble Earl (Hardwicke) had suggested that there was illegality in the course

which the Government had taken since that vote was given, he would say a word in explanation. Undoubtedly it was not in the power of the Government, without an Act of Parliament, to suspend the operation of any Act of Parliament enforced at the time being, and the Government had not taken upon themselves to do so. The only matters of obligation cast upon the Government by the Act of Parliament was that the Admiralty or the War Office should appoint medical officers for certain purposes, to act in certain hospitals, but he could not discover in the Acts any direct obligation laid on Government, either expressly or by necessary implication, to take steps with the view of putting in active force those powers of the Acts which had reference to the compulsory examination of certain persons taking place. The power of compulsory examination depended upon an order of the justice of the peace, which order might be made when information on oath was laid before him by a superintendent of police and supported by certain proofs. The Government had not taken upon themselves to prevent any justice of the peace from acting in the manner authorised by the Acts upon information laid by a superintendent of police, and there was nothing in the Acts which imposed upon the Government the duty of using any powers which they possessed to set in motion the police authorities for that purpose. Undoubtedly, so long as there was no vote passed by the House of Commons, the Government should take measures by the employment of police, to see that the Acts were put in operation when they thought that public advantage would result from it; but when the House of Commons passed a vote expressing an opinion by a large majority that there should not be compulsory examination, the Government were, at all events, not transgressing any part of the enactments, nor were they neglecting any obligation laid on them by the Acts if they abstained from taking active means contrary to the resolution of the House of Commons.

HOUSE OF COMMONS.—THURSDAY, MAY 10TH.

THE CONTAGIOUS DISEASES ACTS.

In answer to Sir H. D. Wolff,

Sir W. V. HARCOURT said the withdrawal of the Metropolitan Police from the districts protected under the Contagious Diseases Acts until Parliament had been enabled to decide on the Government Bill for the protection of young girls would not be consistent with the view the Government had taken. The Bill would be introduced in the House of Lords, and was strictly intended to carry out the recommendations of the Lords Committee. Its object was not the direct and immediate object of the Contagious Diseases Acts.

In further answer to Mr. Puleston,

Sir W. HARCOURT stated that, for the present, the removal of some of the inspectors would be postponed.

Literature.

COURTY ON DISEASES OF THE UTERUS. (a)

As is stated on the title-page, the preface to this work is written by Dr. Matthews Duncan. In it he tells the reader that "among books devoted to diseases of women, none has been, or is, more important than that of Professor Courty, of Montpellier." He says further that "it is certainly a great boon to the English-speaking peoples to have Courty's work translated; for the great mass of medical men are, unfortunately, ignorant of French, or not familiar enough with that language to enable them to use the book in its original form."

If a man is asked to write a complimentary preface to a book, if he be at all anxious to please his petitioner he will

(a) "Practical Treatise on the Diseases of the Uterus, Ovaries, and Fallopian Tubes." By A. Courty, Professor of Clinical Surgery, Montpellier. Translated from the Third Edition by his pupil, Agnes M'Laren, M.D., M.K.Q.C.P.I. London: J. and A. Churchill, 1882.

generally contrive to say something flattering. This may be done without reflections, the reverse of flattering, on the very people whom it is the preface writer's desire to interest favourably. We do not say that Dr. Duncan's praises are undeserved, but we hope and are rather inclined to believe that his reflections on the French acquirements of his medical brethren are.

With regard to the work itself in its English dress we accord it a hearty welcome. No man can be a truly accomplished physician who is ignorant of the medical thought of all countries but his own. There can be no doubt that a good French author has a better chance of being read if his book is published in English than if it remained in its original form. This, however, is not altogether owing to ignorance of French on the part of medical men, but rather to the fact that French books are not advertised as fully in English papers as English books are.

The work commences with an excellent, exhaustive introduction on the anatomy, physiology, and teratology of the organs of generation. This will certainly bear comparison with the corresponding chapters in any English work, if, indeed, it is not superior in this most important particular. It covers 94 pages, and is well worthy of careful study.

One hundred and thirty-nine pages are devoted to a consideration of uterine diseases in general. This part is also very good; but, bearing in mind the fact that it is after all but an introduction to the subject of uterine diseases in detail, in dealing with which most that is here stated has to be repeated, it is open to question whether it would not have been better to have cut away freely from this part so that much needless repetition might have been avoided. Whilst on the subject of redundancy, we may also remark that a great number of the plates are given in more than one place. Thus plates 42 and 45 are identical, plate 86 is identical with plate 219, 87 with 221, 89 with 223, 90 and 224, 91 with 227, 29 with 228, 32 with 230, and so on. A judicious economy in the avoidance of repetition of matter and plates would have been of advantage.

Dr. Courty's views on the etiology of the various displacements, deviations, flexions, &c., will be novel to many English readers; and being the views of a distinguished gynaecologist, they are deserving of thoughtful consideration. It is doubtless in consequence of his peculiar views that he employs Graaf's cradle pessary in the treatment of retro-flexions.

The subject of diathesis in relation to uterine diseases is well worked out, with the result that a flood of light is thrown upon subjects usually left obscure in works in our own language. It may be that the question of diathesis is becoming, or has already become, old-fashioned; but we believe it to be not the less important and deserving of study.

The chapters on ovarian and fibroid tumours of the uterus are already a little out of date, so rapid are the changes taking place in the treatment of these affections. What, for instance, shall we say of the following, on page 230?—"Lastly, comes ovariectomy, the most serious of all these operations—so serious that it has not yet been generally adopted." This surely must have been written for the first edition of the work, and preserved in the present one through simple inadvertence.

The translator has done her work, on the whole, well. Errors there are, but they are not more numerous than might be expected in a work of such magnitude. We observe that "phenomena" is used in the singular. The word (l) "vulva" is made use of; also "lochia" is employed for "lochia"; "presented" for "preserved," page 418; "chief" for "deep," page 633; and at page 464 ol. ricini is included amongst the saline purgatives. Notwithstanding these few errors, for which the translator must bear the blame, we may say of the work itself that it is evidently the expression of a scientific mind. The illustrations are both numerous and good, and everything connected with the get-up of the work is creditable to all concerned.

STOKES ON DISEASES OF THE CHEST. (a)

It is with a mixed feeling of satisfaction and of regret that we have perused in our mature years this reprint of a book which was the delight of our student days. At that period

(a) "Stokes on Diseases of the Chest;" with a Memoir of the Author by Dr. Acland, F.R.S. Edited for the Sydenham Society by the late Dr. Alfred Hudson. Medium 8vo, pp. 566.

we borrowed it, for it was already out of print; and in reading it we breathed the hope that the illustrious author would put forth a second edition. This has now been done from the notes of William Stokes, placed in the hands of Alfred Hudson for this purpose. Having said so much, we feel that the reviewer's task is over, for there are occasions on which silence is more powerful than speech. We will merely say that the work is done in a manner worthy of these two lights of the Irish School of Medicine, and we will not presume to review a medical classic which ought to be in the hands of every member of the profession as a source of information and as a beacon of the path he ought to tread. We must, however, pay a passing tribute to the touching beauty of the memoir of Stokes drawn up by the loving hand of Henry Acland. There is no more noble feature in the character of Stokes than the feeling of affection and veneration which he inspired in the minds of his English professional brethren who had the privilege of his friendship. Dr. Acland's memoir is creditable alike to the biographer and to his subject, and it is impossible to read it without emotion.

INTERNATIONAL ENCYCLOPÆDIA OF SURGERY. (a)

THE medical profession is now so far reaching, and extends into so many details and specialities, that it would be impossible for any one intellect or any one lifetime to master its full extent. Still, it has been well said that a properly-informed medical man ought to know "something of every one of its departments and everything of some one of them." We fondly imagined that we complied with this requirement until we looked into the article upon "Arrow Wounds" in this Encyclopædia. Our conscience told us that our knowledge of this subject was simply nil, and yet we find fifteen pages of most interesting matter, embracing the experiences of the United States Army Medical Department in their brushes with the frontier Indians, and, like all the rest of the book, beautifully illustrated with pictures of instruments and of pathological specimens. The rest of this volume contains articles on more ordinary subjects—upon contusions; upon wounds, from the pen of Mr. Bryant; upon antiseptic surgery; upon poisoned wounds; upon gunshot wounds, by Prof. P. S. Connor, of Cincinnati; upon the effects of heat; upon those of cold; upon abscesses; upon ulcers; upon gangrene; upon venereal diseases of all kinds; and upon surgical diseases of the skin.

We have merely indicated the scope of the present volume; but it would be impossible in the limits of a review to enter into the details of these articles, which contain the newest and best information in every department. Judging by the two volumes, we doubt if the task can be accomplished in six of them; and we think it not unlikely that, after the example of Ziemssen, a supplementary volume or volumes will be required. At all events, the authors can say that they have completed *monumentum perennius* are in putting forward to the world such an exposition of the surgery of the nineteenth century. The illustrations, both chromo-lithograph and woodcut, are superb, and scattered with a lavish hand. The work leaves nothing to be desired, and proves what the late International Congress first showed us, that medical and surgical Europe will have to work hard to hold her own with the rising school of America.

A PHARMACEUTICAL PHRASE BOOK. (b)

As Dr. Barry does not in his short preface, tell us for what class of reader his little work has been especially designed, it is at first not quite obvious that it could be worth while to produce a German-English phrase book of which the subject matter is entirely pharmaceutical. When, however, one remembers that the German is ubiquitous, that there are few large English laboratories which do not number among their staff at least one assistant of that nationality, that in most American cities a knowledge of German is as much a necessity as a knowledge of English, the *raison d'être* of this little book becomes apparent. Admirably conceived and carried out in its plan, with both its German and English

columns not only sharply classified but alphabetically arranged, it is in fact a chemist's and druggist's technical dictionary. Condensed into its fifty pages are words and terms used in pharmacy, an almost exhaustive list of German-English equivalents for the names of drugs, preparations, "druggists' sundries" and pharmaceutical apparatus, names of diseases, and technicalities found in English prescriptions. Some examples of dialogue and of English correspondence seem hardly likely to prove so practically useful, but, considering the grotesque errors with which works of this nature usually abound, we accord no small praise to the author, when we are able to say that not alone not here, but throughout the book, have we discovered a single solecism or a single sentence which is not worded in perfectly idiomatic English. If its German critics be able to speak of it as favourably in this respect it cannot fail to secure a well-merited popularity.

PASS LISTS.

Royal College of Surgeons in Ireland.—At a meeting of the Court of Examiners held on Monday, the 2nd of April and following days, the following gentlemen passed the several examinations for the first half of the Letters Testimonial of the College:—

Frederick W. Allwright, Arthur J. Barlow, Patrick J. Barry, Louis A. F. Bates, John Bernal, William Boske, John J. Buggy, Henry J. Butler, Francis L. Carte, Robert H. Clemant, William Clifford, Arthur Cole, James V. Collins, Robert Cross, Samuel A. Crotty, Thomas Crowe, Alexander Cuffe, Godfrey O. Cuppalidge, Thomas J. Daly, William J. Darby, John J. D'Arcy, Joseph C. Dormer, Ignatius P. Doyle, William Dillon, Thomas G. Drake, George A. Draper, John Emerson, Peter J. Fitzgerald, George B. N. Flanagan, William E. Grunty, Charles H. P. O. Graves, John W. Greene, John H. Griffin, Frederick S. Heuston, Denis Kennedy, John M. P. Kennedy, Edmund D. Latouche, Frederick D. Lawson, John Lowney, Francis B. Manning, Nathaniel S. Manning, Francis W. M'Cauley, Francis J. M'Guire, John M'Grane, John M'Guinness, Alfred H. Middleton, Thomas Millerick, Cornelius Molony, Andrew Murphy, Albert W. Myles, Llewellyn T. M. Nash, James Normile, Wilson W. Nugent, Andrew J. O'Flanagan, William H. B. Robinson, William W. Scott, Edward N. Smartt, Henry W. Smartt, Edward C. Stack, Alexander Stewart, Whitley Stokes, Frederick J. W. Stoney, Francis W. Sullivan, William L. S. Symes, Augustus J. O. Tabuteau, Lancelot A. Whitecroft, George R. Williams, and John F. Yates.

On Friday, the 20th April, and following days, the following gentlemen, having passed their final examinations for the Letters Testimonial, were admitted Licentiates of the College:—

William G. Butler, James L. Callaghan, Loftus Campbell, Michael Carr, Joseph Coffey, Sir Charles Coote, Bart., Charles A. Daley, Quinton E. Darling, Patrick T. Dillon, Alfred E. Dugdale, Sinclair Finlay, George Fisher, Arthur O. Fitzgerald, John R. Fitzgerald, Diego Ganon, James Hamilton, Allen H. Hanly, James J. E. Jackman, Joseph J. Jackson, Andrew J. G. Kelly, Christopher P. Kelly, Wm. Love, Michael J. M'Cartan, Bernard A. M'Girrity, Alexander J. M'Kenzie, Charles L. Magill, Henry Morhead, Thomas Moore, Charles G. A. Morier, Francis S. Morrison, Patrick H. Murray, Joseph Niblock, Robert D. Patterson, John Robinson, Albert W. Shepard, John C. Seady, Thomas W. Spronk, John Taylor, Henry R. Todd, William A. Tomlinson, Henry E. A. Warren, and James L. E. Somers.

King and Queen's College of Physicians.—At the April examinations the following candidates obtained the Licences in Medicine and Midwifery of the College:—

MEDICINE.—Campbell Boyd, Shepherd Boyd, Michael Carr, Thomas Gibson Henry Hall, Patrick Hoey, Powell Hudsmith, Andrew John Kelly, Edward Emanuel Lennon, Thomas M'Inerney, Alex. Linton Mackenzie, Matthew Joseph M'Quaid, George Morgan, Charles George Drummond Morier, Henry Joseph O'Brien, James Dwyer Ryan.

MIDWIFERY.—Campbell Boyd, Shepherd Boyd, Michael Carr, Thos. Gibson Henry Hall, Patrick Hoey, Andrew John Kelly, Edward Emanuel Lennon, Thomas M'Inerney, Matthew Joseph M'Quaid, George John Morgan, Charles Drummond Morier, Henry Joseph O'Brien, James Dwyer Ryan.

MEMBERSHIP OF THE COLLEGE.—George John O'Reilly.
CERTIFICATE IN SANITARY SCIENCE.—Thomas Lane.

Royal College of Physicians of Edinburgh and Faculty of Physicians and Surgeons of Glasgow.—The following candidates, having passed the Final Examination for the double qualification, were admitted Licentiates of the College and Faculty at the recent sittings:—

Gammel, Arch. B., Glasgow.	Oakes, Henry, Glasgow.
Mackie, John, Aberdeen.	Read, Henry, M. A. Cantab.
Middleton, Wm., Glasgow.	San Francisco and Glasg.

Faculty of Physicians and Surgeons, Glasgow.—The following candidates, having passed the Final Examination, were admitted Licentiates at the recent sittings:—

Bosny, Alfred F., London.	Macdonald, Colin, Glasgow.
Carr, John A., Glasgow.	MacLachlan, D., Glasgow.
Jones, Gordon G., Glasgow.	Tarleton, E. E., Birmingham.

(a) "International Encyclopædia of Surgery." Edited by John Ashurst, jun., M.D. In six volumes. Vol. II. London: Macmillan and Co. Royal 8vo. Pp. 754.

(b) "A Pharmaceutical Phrase Book" *Englisches Conversations-Buch für Pharmaceuten.* Von Dr. Th. D. Barry. Berlin: Julius Springer. 1883.

University of St. Andrews.—The following registered medical practitioners, having passed the required examinations, had the degree of M.D. conferred upon them on April 18th:—

Andrew, James Lawton, L.R.C.P.Ed., M.R.C.S., Moseley.
 Artles, Harvey Eustace, F.R.C.P.Ed., Adelaide.
 Bown, Andrew, M.R.C.P. & L.R.C.S.Ed., London.
 Fisher, Henry Francis, L.R.C.P.Ed., L.F.P.S.Glas., Liverpool.
 Gambier, Thomas, M.R.C.S., L.S.A., St. Leonards-on-Sea.
 Giddings, William Kitto, M.R.C.P.Ed., M.R.C.S., Calverly, Leeds.
 Hanson, John Edw., M.B. & C.M. St. And., Huddersfield.
 Jamieson, James, F.R.C.S.Ed., Edinburgh.
 Jay, Fredk. Fitzherbert, L.R.C.P.Lond., M.R.C.S., Slough.
 Kempster, Wm. Henry, L.R.C.P.Ed., M.R.C.S., London.
 Smith, Thos., F.R.C.P.Lond., F.R.C.S.Ed., Woodley, Stockport.

Notices to Correspondents.

A CASE FOR GENERAL SYMPATHY.

WE are asked to acknowledge the receipt of the following subscriptions towards the "Hurford Fund," in response to the letter which appeared in the *Medical Press* of April 18:—Amount already acknowledged, £342 14s. 6d.

C. M. Elliott, Esq., £5 5s.; Thomas Smith, Esq., £3 3s.; J. E. Meredith, Esq., £2 2s.; E. B. Holland, Esq., £2 2s.; C. Elliott, Esq., £2; George Kell, Esq., £2; Dr. Philipota, £2; Miss E. Parrott, £1 10s.; Dr. Travers, £1 1s.; C. Crawford, Esq., £1 1s.; E. H. Addenbrooke, Esq., £1 1s.; Dr. Bull, £1 1s.; B. £1 1s.; W. Davies-Colley, Esq., £1 1s.; Dr. Bisset Hawkins, £1; Surgeon-Major N. V. Churchill, £1; T. F. Fernandez, Esq., £1; Dr. W. W. Stainthorpe, 15s. 6d.; Joseph Williams, Esq., 10s. 6d.

MR. ENSOR (Liverpool).—There are but three other cities in the world beside London with a population exceeding a million—viz., Paris, with 2,240,000; New York, 1,250,000; and Berlin, 1,190,000. Pekin may possibly come under this category, but the number is unattainable. Taking the annual rates of mortality of these four cities, it is curiously enough in inverse ratio to the size, London, the largest, having the lowest death-rate, and Berlin, the smallest city, the highest death-rate.

A POOR-LAW MEDICAL OFFICER'S EPITAPH.

THE correspondence between the Brentford Board of Guardians and Dr. Whitmarsh (who has been officially dismissed from his post of medical officer for the district of Hounslow) has terminated with a letter from the doctor, in which he enclosed what he terms his "official epitaph," as follows:

"To the memory of Michael Whitmarsh, M.D., M.R.C.P.; he was sacrificed on the altar of slander. He departed his parochial life on the 9th day of May, 1888, having served the Brentford Union faithfully for 22 years. They repaid him, not with a pension, but with injustice and want of fair play, which has at all times been their strong point.

"Farewell, O Board! I've had enough of thee,
 And carest not what thou canst say of me.
 Thy smiles I court not, nor thy frowns I fear;
 I'm 'Dilke'd,' but yet I do not feel so queer.
 What faults you see in me take care and shun,
 And look at home, O Pharisees—there's something to be done."

HONOURS TO MEDICAL MEN.—The *Wiener Med. Zeitung* has the following in its last issue: "The Queen of England, in recognition of his past services in the cause of science, has bestowed the dignity of a baronetcy on Spencer Wells. *England honours its great men!*" The italics are not in the original.

MR. WATSON is referred to the *Students' Journal* for an answer to his inquiry. We do not publish examination questions.

A M.R.C.S.—We quite coincide with the opinion expressed by your friend; it is undoubtedly the best text-book for the higher examinations.

THE COST OF VEGETARIAN DIET.

DR. NORMAN KERR, whose enthusiasm in the cause of temperance in drink is well known, has initiated a crusade against gluttony. On Friday last a party, consisting of nearly 100 *employes* of the Marylebone Vestry, were entertained at a vegetarian supper at the "Walmer Castle" Coffee Tavern, at his invitation, Dr. Richardson, F.R.S., being also present. The repast consisted of three courses, accompanied by a plentiful supply of brown bread and a cup of excellent cocoa for each guest. A "hotch-potch" soup was first served. The ingredients in this were potatoes, turnips, carrots, leeks, celery, green peas, parsley, and butter. It was palatable, and it is claimed for it that it is nutritious. The next dish was a savoury pie made up of haricot beans, flour, onions, and butter; and then followed the sweets, in the shape of a pleasant hot mess of rhubarb, rice, and sugar. The cost of the entire meal was less than £1 5s., being at the rate of 8d. each person. The food was heartily enjoyed.

F.R.M.S.—Naphthol bears the same relation to naphthalene that carbolic acid bears to benzene, possessing the properties and characteristics of phenol. There are, however, two varieties, which probably accounts for your want of success. Naphthol ointment has proved most valuable in the treatment of scabies and some other skin affections, its curative properties being surprising.

AN UNCERTAIN HEALTH OFFICER.—We cannot better or more fully answer your queries on the requirements of the "Notification of Infectious Diseases Bill" than by referring you to the series of articles on the subject in the early numbers of our present volume.

DR. O'FLANAGAN—Your letter is unavoidably held over.

T. E. A.—The essential treatment in all these cases is rest, and the utmost endeavour to secure complete physiological repose should be made. Your patient's age is decidedly favourable to recovery, and

the case should, with care and attention, be safely piloted to restoration.

SOUTH EASTERN.—Your query should be addressed to the editor of a "Social" paper. We have no means of replying to it; nor is it a subject suitable to be referred to in the columns of a medical paper.

MEETINGS OF THE SOCIETIES.

THURSDAY, MAY 17TH.

HARVELAN SOCIETY OF LONDON.—At 8.30 p.m., Mr. Gant, On a Case of Umbilical Hernia, with co-existing Peritonitis, simulating Strangulation.—Mr. Cripps Lawrence, On a Case of Broncho-pneumonia occurring in a Child.—Dr. Buzzard, On the After History in some Cases of Syphilitic Disease of the Nervous System.

FRIDAY, MAY 18TH.

ACADEMY OF MEDICINE IN IRELAND (Medical Section).—At 8.30 p.m., Living Specimens: Dr. C. J. Nixon, Case of Aortic Aneurism, with Patency of Aortic Valves; Anomalous Physical Signs.—Mr. Copping, A Case of Paralysis following Gun-shot Wound of the Spinal Cord.—Specimen exhibited by card: Dr. J. Magee Finny, Nodose Condition of the Hair.—Papers: Mr. Story, Three Cases of Exophthalmic Goitre.—Dr. Walter Smith, Successful Removal of a Laryngeal Polypus by Voltolini's Method.—Dr. Henry Kennedy, On Dilatation of the Colon.

Vacancies.

Dalrymple Home for Inebriates.—Medical Superintendent. Salary, £150, with board, &c. (See Advt.)

Denbighshire Infirmary, Denbigh.—House Surgeon. Salary to commence at £25, with board and residence. Must be conversant with the Welsh language. Applications to be sent to the Secretary before May 26th.

Glasgow Royal Infirmary Medical School.—Teacher of Physiology. Applications to the Secretary on or before June 15th.

Glasgow Royal Infirmary Medical School.—Teaching of Chemistry. Applications to be lodged with the Secretary not later than June 15th.

Glasgow Royal Infirmary.—Extra Dispensary Physician. Applications to be lodged with the Secretary not later than June 1st.

Manchester Royal Infirmary.—Resident Medical Officer. Salary, £50, with board and residence. Applications to be directed to the Chairman of the Board on or before May 24th.

Poplar Hospital for Accidents, Blackwall, E.—House Surgeon. Salary, £100. Also Assistant House Surgeon. Applications to be sent to the Secretary on or before May 22nd.

Appointments.

COCHRAN, C. H., L.R.C.P.E. & L.R.C.S.I., a Surgeon to the Reading Dispensary.

DONKIN, H. B., M.B.Oxon., F.R.C.P.Lond., Physician to the Westminster Hospital.

DRESCHFIELD, J., M.D., M.R.C.P.Lond., Honorary Physician to the Royal Infirmary, Manchester.

FROST, W. A., F.R.C.S., Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.

GRAHAM, C. E., M.R.C.S., Surgeon to the Royal Albert Edward Infirmary, Wigan.

HARTRIDGE, G., F.R.C.S., Assistant Surgeon to the Royal Westminster Ophthalmic Hospital.

LEGGE, R. J., M.D. Royal Univ. Irel., L.R.C.S.Ed., Assistant Medical Officer to the Derby County Asylum.

MARTIN, Dr. J. W., Third Surgeon (acting) to the 2nd Volunteer Battalion, York and Lancashire Regiment (Hullamshire Rifles).

ROOCROFT, W. M., M.R.C.S., L.R.C.P.Ed., Medical Officer to the Royal Albert Infirmary, Wigan.

SHEARIN, Mr. E. Colby, House-Surgeon to the Lincoln County Hospital.

STEWELL, G., M.D.Ed., M.R.C.P.Lond., Assistant Physician to the Royal Infirmary, Manchester.

WATSON, J. C., Medical Officer to the East Bishoptonmouth District and Sunderland Districts of the Sunderland Union.

Births.

BECKINGSALE.—May 9th, at Sydney House, Chiswick, the wife of D. L. Beckingsale, M.D., of a daughter.

LEPTWICH.—May 7th, at 281 Kennington Road, London, the wife of Ralph Leptwich, M.D., of a daughter.

BAYNER.—May 7th, at Tiviot Dale, Stockport, the wife of Edwin Bayner, M.D.Lond., F.R.C.S., of a daughter.

Deaths.

BRUCE.—April 30th, at 70 Old Street, London, E.C., suddenly, of apoplexy, Robert Bruce, Surgeon, aged 60.

FITZGERALD.—May 7th, whilst on duty at the hospital, John Fitzgerald, B.A., B.M., T.C.D., Resident Surgeon Whitworth Hospital, Drumcondra.

HAMILTON.—April 4th, at sea, on board the *ss. Larcies*, John Robert Hamilton, L.R.C.S.I., aged 25.

JONES.—May 5th, at Blycote, Enfield Highway, after a short illness, T. W. M. Jones, M.D., aged 75.

KEATINGE.—May 9th, at 47 Belgrave Square, Rathmines, Patrick Keatinge, M.D., late of Callan, co. Kilkenny, aged 82.

SHORT.—April 37th, at Clenchwarton, Norfolk, William Hooper Short, L.R.C.P.Ed., aged 42.

SMITH.—May 5th, at the residence of his son, Bisleigh Rectory, George Pysmont Smith, M.D., late of Leeds, aged 67.

YATES.—April 19th, at his residence, Tregew, Falmouth, Walter Yates, F.F.P.S., late of Nottingham.

ON

HYSTERICAL CONTRACTION OF TRAUMATIC ORIGIN. (a)

By J. M. CHARCOT, M.D.,

Professor to the Faculty of Medicine, Paris; Physician to the Salpêtrière Hospital; Fellow of the Clinical Society of London, &c.

(Continued from page 419.)

LECTURE II.—TWO CASES OF HYSTERICAL CONTRACTION OF TRAUMATIC ORIGIN.

GENTLEMEN,—You will remember that in our last lecture I expressed the intention of comparing two cases which presented themselves to us at the same time, of the nature of a hysterical contraction, due to a traumatic origin, the one being occasioned by a wound from a broken glass, and the other owing to a superficial burn. These two cases present features strikingly identical, notwithstanding that the one is that of a girl, æt. 16, and the other that of a vigorous man, a smith, æt. 35, married, and the father of several children. Since then the young girl has been the subject of close attention; while, with respect to the male subject, whom we were able to submit to you only the other day, he was committed to our charge by M. Debove, under whose care he was at Bicêtre. I gladly avail myself of the opportunity of making in your presence an exhaustive examination of the case. I do so with especial pleasure, seeing that the case is one unquestionably rare, instructive in the first degree, and consequently worthy of commanding your attention. Before, however, proceeding with this case, it is necessary to complete certain details with respect to the young patient who occupied our attention in the last lecture. You will not forget that in all cases of hysteria the possibility of malingering ought always to be present to the mind of the clinician, as in this case sometimes real symptoms are exagger-

ated, while in other the symptoms are totally those of imagination. Everyone knows, indeed, that this proneness to lie and to deceive, as a work of art, so to speak, sometimes to create a sensation, at other times to excite pity, is a common occurrence in cases of hysteria. This is an element which we encounter at each step of this disease, and which for many a day cast disfavour on the studies appertaining to it.

But at present, notwithstanding that the subject of hysteria is often handled and raked up, it is as difficult as any one could wish to discriminate between the simulated and real symptomatology. This may be well illustrated by a reference to a case to which I directed your attention during the past year. The case was one of catalepsy provoked by hysteria. The question is this, Was this condition simulated to the extent of deceiving the clinician experienced in these questions? It is generally believed that if a cataleptic subject be placed with the arm horizontally extended, that attitude is maintained so long that this feature alone would obviate all suspicion of simulation. This observation does not accord with my experience. After from ten to fifteen minutes the arm of the cataleptic commences to descend, and from twenty to twenty-five minutes it takes the vertical position in obedience to the laws of gravity. But a vigorous man attempting the same is able to maintain it during the same limit of time. Hence a distinctive feature of diagnosis is sought. On the malingering and on the cataleptic we apply a *tambour à réaction* on the extended arm, which registers the least oscillations of the member. Again, a pneumograph is placed upon the chest to obtain the respiratory curves. The following are the results obtained:—On the cataleptic the pen which acts with the *tambour* applied upon the arm traces on the registering cylinder a perfectly straight and regular line; in the case of the malingeringer, on the contrary, the line is at first straight, then broken, and finishes by presenting great oscillations in series. The tracings furnished by the pneumograph are equally significant: in the cataleptic the respiration continues mild, superficial, and regular to the end; in the malingeringer the trace presents two distinct portions—at first, the

(a) Translated from *Le Progrès Médical*.

respiration is regular and normal, then, corresponding to the oscillations of the members which indicate muscular fatigue, there is observed irregularity in the rhythm and extent of the respiratory movements, the rapid and deep respiratory depressions which accompany the phenomena of effort.

The cataleptic does not feel fatigue, the muscle without effort, or the intervention of the will. The malingerer is betrayed by the trace of the member indicating fatigue, and by the respiratory trace, which indicates the effects of fatigue. We have in these days resorted to a somewhat similar manoeuvre to test the contraction of our young patient. The forearm is applied on a table to which the back of the hand is firmly attached by means of a bandage. A small sling embraces the thumb. This is attached to a cord which passes through two pulleys, and suspends the scale of a balance, in which is placed a weight of a kilogramme. The experiment is continued for half-an-hour. During that time the thumb is progressively elevated, and is separated more and more from the index finger. At the end of the experiment the thumb immediately resumes its former position, and without appearance of fatigue, is as firmly applied as formerly. During all this time the pneumograph applied to the front of the chest registers each respiratory movement, and the trace demonstrates that the respiration is regular, not deep, normal, and equal from the commencement to the end; there is nothing absolutely approaching the respiratory trouble which characterises the phenomena of effort.

Substituting in like manner a vigorous young man—aneant patient—he gives voluntarily his left hand, putting it in the particular attitude of our young patient. The thumb, which at the commencement of the experiment has been applied against the index finger, is submitted to the same continuous traction, and during the same time—viz., half-an-hour. By degrees it gives way, and is progressively withdrawn from the index finger in spite of the voluntary effort of the person experimented on. Hitherto, nothing distinguishes between the real case of disease and that of health, but turning to the respiratory tract the contrast is manifest. At the commencement, during the first few minutes, the respiration is equal and regular, but soon it becomes disordered; the inspirations are prolonged, marked by strong depressions, and separated by large horizontal interlines. The phenomena of effort then become quite evident. Hence, thanks to this method of investigation, the respiratory tracing reveals deception.

In cases of hysteria one cannot be too strongly fortified with proofs. But you will observe that the proof to which we submitted our young patient is in some manner superfluous, as we have had already numerous proofs of the real nature of the affection. I think that I have sufficiently insisted, and that it is established in your minds, that the phenomena which we have already studied together are perfectly real pathological phenomena, in which the will of the patient participated in no sense whatever. I will show you instantly that all the symptoms of our young female patient apply one by one to our male patient, whose case I proceed to consider. [The hysterical phenomena of the young girl totally disappeared under treatment by galvanism, M. Charcot having shown her completely cured of her deformity on the 12th January, 1883.]

I will preface by a few words on the subject of hysteria in the male. Then hysteria does occur in the male? Yes; and more frequently than one would be disposed at first sight to grant. The subject of hysteria in the male is one to which physicians have directed some attention during the past few years. Thus, no less than five inaugural dissertations on the subject have been presented to the Faculty of Medicine of Paris from 1875 to 1880. Déjà Briquet, in his excellent work, has expressed the opinion that for every twenty women affected with hysteria in Paris, at least one man is found

similarly affected. This estimate appears to me somewhat too high. M. Klein, the author of one of the theses of which I have spoken, was able to collect seventy-seven cases of male hysteria, to which he added three which came under his own personal observation, thus giving the considerable number of eighty; hence we must conclude, at least, that in man hysteria is not truly a very rare disease.

An important fact disclosed in the same work is that where hysteria is developed in man it is most frequently hereditary. This circumstance was noted 23 times in 30, and the heredity was on the maternal side. Hence, hysteria in the mother frequently occasions hysteria in the son. Another observation was made by Dr. Russell Reynolds, of London, viz., that hysteria in the male most frequently appears at the adult age, after 14, from 20 to 30, and sometimes even later. Without doubt hysteria in the male may be encountered before puberty, from 5 to 14 years; but hysteria in the adult is more common. Another point worthy of note: hysterical male patients do not always present characters of femininity; they are frequently robust men, presenting all the characteristics of the male sex, possibly belonging to the military, married artisans, and fathers of families, men in a word in whom it is surprising to find a disease commonly regarded as peculiar to the female sex. Finally, I would add that in man, as in the female, this nervous may present itself in a subdued and modified form; and it is quite established, on the other hand, that it may be found in man in its most characteristic form of hystero-epilepsy, and grande hysteria. Last year I cited to you many observations fairly justifying these facts. At present I shall only point out the analogous psychic modifications in the two sexes, relatively to the following points:—

1st. The sensorial and sensitive hemianæsthesia which almost certainly characterises hysteria (when the effects of lead-poisoning and alcohol are wanting)—that hysterical hemianæsthesia, in a word, may be encountered equally in the male as in the female. The limitation even of the field of vision, and the transposition of the limits of the field of vision for colours even exist equally. I have already demonstrated to you an example.

2nd. The ovarian irritation, one of the most frequent symptoms of female hysteria, has its counterpart in the male, in whom, in certain cases at least, the irritation of a testicle retained in the abdominal ring, or pressure of the testicle arrests or provokes the attack.

3rd. Likewise we find hystero-genetic points in the man, with the same characters as in the female; but in him the points of election are especially the crown of the head, the sides of the chest or abdomen, and especially the left flank.

4th. Again, the series of the phases of the great hystero-epileptic seizure are found equally in the male with the female (*vide* among other cases those of Bourneville and Olier, and of M. Fabre, of Marseilles, without including the four or five cases of the same kind that I have myself encountered).

5th. The paraplegic or hemiplegic paralysis, with exaltation, or on the contrary, disappearance of the tendon reflexes, is a phenomenon which is sometimes observed, much more frequently than contraction, which seems to have been rarely noticed.

But you will not expect to find, in the male subject, all the striking manifestations of hysteria united. The hysterical nervous is more frequently found in him modified, and wanting in its classic attributes, in a maimed form, so to speak, and it is thus that we will find it in the patient of whom I am about to speak to you. I hope to succeed in persuading you, notwithstanding the absence of these grand characters, that it is with a case of hysteria that we have to deal.

(To be concluded.)

ON THE DIFFICULTY OF DIAGNOSING TRUE SYPHILITIC DISEASE IN WOMEN, AND THE NATURE OF ITS CONTAGION. (a)

By C. H. F. ROUTH, M.D. Lond.,
Fellow of University College, London.

(Continued from page 420.)

THE amount of (syphilitic and venereal diseases) among the inmates of brothels as compared with other prostitutes, and the effect upon the men, who, under a false sense of security, frequent them, has been accurately determined by the official Belgian and Parisian returns. (See Tables IV., V., VI., VII., VIII.)

TABLE VII.

Messa. Puche and Fournier found by careful interrogation that out of 873 venereal men, who had been contaminated,

- 625 were by licensed prostitutes ;
- 52 " kept women or others ;
- 24 " married women ;
- 20 " maid-servants ;
- 100 " workwomen ;
- 4 " clandestine prostitutes.

(a) Read before the Medical Society of London.

TABLE VIII.

Mireux states that out of 100 syphilitic cases in his private practice and in his dispensary among men,

- 62 were referred to brothels ;
- 38 to city prostitutes, i.e., isolated or clandestine.

In Belgium, where the system is more general, more encouraged, where even married women are allowed to misconduct themselves in houses of ill-fame and the law cannot touch them, for all is lawful in these dens of infamy, the disease is even more severe than in Paris.

This untoward result of the injurious influence of brothels in spreading disease may yet be accounted for in two other probable ways, and, although I would not say it is so in England, I must add that, in France they are both entirely a limited. One is the inadequacy of the examinations made. This would follow from the opinions before expressed by Ricord, Lancereau, Langenbeck, Nixon, who all recommend different modes of examination ; but it is still better explained by, 1st, The rapidity and number of examinations at a time ; and, 2nd, The carelessness with which they are made, which entails the communication of disease from one woman to another by the use of infected specula.

1st. In 1841, the year in which the speculum was introduced by Ricord in these cases, Pelacy states that from eighty to ninety women had to be examined in one hour to one hour and a half.

From the years 1855 to 1870, Carlier gives the figures, at the dispensary 5,050 examinations have to be made by one medical man in twenty-six days, six hours daily, i.e., about thirty-two per hour, allowing something under two minutes for each woman. M. Clerc is stated upon the authority of Routier, of Ballemont, that he visited one hundred and twenty women in one hour, i.e., two women in a minute.

2nd. Mr. Yves Guyot asserts that it has been directly communicated by the speculum, and he is not alone in this assertion. This source of contamination is equally admitted as in full operation by such men as Lancereau, Fournier, Giersing, and many other reliable writers. The hurry of examination itself may account for these accidents. M. Guyot himself asks, and very properly, if in Naples two hundred women have to be examined in two hours, and with the same instrument, how could it be washed for each patient.

In England the same result obtains, as evidenced by the returns of the Contagious Diseases Acts. True syphilis as it occurs in the protected districts is much more severe than when it occurs in the unprotected districts. Dr. Nevins has shown from the official returns that comparing fourteen protected, with fourteen unprotected army stations, the number constantly sick in hospital had increased in the former from 26.85 to 28.58, and in the latter decreased from 28.67 to 24.80.

Its severity is further proved by Dr. Lawson's own tables.

The average ratio or percentage of secondary syphilis in primary sores are stated as follows by Dr. Lawson : -

Periods.	Protected Stations.	Unprotected Stations.
1861-62 ...	34.1	29.8
1867-72 ...	37.6	31.2
1873-78 ...	56.0	42.4

Thus we have come by the Contagious Diseases Acts to induce a disease which will yield fifty-six cases, where without them it would be only forty-two ; or, in other words, Dr. Lawson affirms that the chances of a soldier contracting syphilis in the protected compared to the unprotected districts is as 36 to 33.

Now, I believe Mr. Lawson made his statement honestly and from conviction. Still later experience gives us a very remarkable commentary on his views. The last Army Report for 1880, which has only been pub-

lished since the close of the late inquiry of the Parliamentary Committee reveals the fact that, in that year the number of men admitted to hospital with primary venereal diseases increased in the protected districts collectively by the enormous proportion of 57 per cent. on the previous year's admissions, against 45 per cent. in all the unprotected districts.

I am not sure whether I am not justified in hazarding a prophecy from these data. I have said that in England the hard sore is to the soft as 1 to 3; abroad, 2·8 to 1. May we not fear that the more you extend the Acts not only is the disease more severe in the protected districts than in the unprotected, but that the tendency is to increase the relative frequency of hard as compared to soft?

If it be, therefore, true that women who undergo examinations, however carefully done, may escape detection, that these examinations are as a necessity in many cases inadequately made, and sometimes the very channels by which a woman is infected; if it be the fact, also, that their secretions, even up to four years after the disappearance of all primary sores, are infectious; if a woman once infected and cured becomes syphilitised, and is, through mediate contagion, in the most favourable condition to infect any number of men, and if the effect of regulation of vice is to increase the number of these, and chase away the younger women, in whom syphilitation does not exist; lastly, if it be shown that brothels, instead of being places of security, are only the most powerful foci of infection; whereas isolated women, and particularly clandestine prostitutes, are very much less liable to spread syphilis—we may fairly ask, Why are brothels tolerated? Now, as we know—I speak at least for abroad, and, as you may judge from the quotations already given—that the opponents and supporters of brothels equally concur in the greater danger of infection from these houses, their maintenance appears inadvisable in every way. But, no! supporters of the licensing system tell us it is the *fons et origo*, the very backbone of all regulation of vice. Here it is the *police des mœurs* (a title which should only be ironically applied) become initiated in their duties. Here it is the poor women learn to have a wholesome dread of these officials. Here it is the officials become acquainted with the appearance and physiognomy of the women, so that, with all the skill of detectives, they may hunt to death their prey if they refuse to submit. From these women the medical examiners learn the diagnosis of disease, and what a benefit to science! In this way they are kept from parading the streets, and thus offending morality. Be it so. *Credat Judæus apella, non ego.*

But what I do feel is this. It has been reserved for our Government in the nineteenth century, under the names of protection and hygiene, to initiate a system by which vice is encouraged and disease increased, and by which poor deluded women are deprived of the assistance of judge, jury, and justice, and reduced to a debased slavery, and all to gratify the vile appetites of degraded libertines and a debauched soldiery.

En résumé, I draw the following conclusions:—

I. Speaking of true syphilis, that is, the sore which leads to constitutional disease, as opposed to the chancre or dirt sore, in women—

1st. That, according to some of the best authorities, and for reasons before stated, it will frequently escape observation, probably in a proportion of five out of ten cases.

2nd. That this is especially true if the examination be confined to the sexual organs only.

II. As regards its contagious character—

1st. That it is communicable by the secretions of a woman to three, perhaps four, years after all primary sores have disappeared.

2nd. That it can be communicated through "mediate contagion," and especially so by a syphilitised woman.

3rd. That it is always more frequent and most severe in women confined in brothels, less so in isolated pro-

stitutes, and least so in clandestine prostitutes, and also is more or less communicable to men in the same order.

4th. That where vice is regulated the chances of getting true syphilis are greater than where it is not, and this is probably also true for secondary syphilis.

Lastly, and, therefore, that the regulation of vice (especially in the establishment of brothels) has a tendency to increase true syphilis, and therefore should be abolished.

SOME REMARKS ON PUERPERAL ECLAMPSIA. (a)

By J. E. BURTON, L.R.C.P. Lond.

Obstetric Physician to the Ladies' Charity and Lying-in-Hospital, Liverpool.

In commencing a paper on this subject it seems very desirable at the outset to fix in our minds what we mean by the name we employ. In the following remarks I shall take the term puerperal eclampsia to be any convulsion coming on during pregnancy, labour, or child-bed attended with loss of consciousness, provided it is not apoplectic, epileptic, hysterical, or anæmic, i.e., that it is not the convulsion that comes on in death from hæmorrhage just as the individual is *in articulo mortis*.

The causes of puerperal eclampsia remained in darkness till 1842, when Dr. John C. W. Lever had the honour of first drawing attention to the relations between albuminuria and puerperal eclampsia in Guy's Hospital Reports. In 1851 Frerichs pointed out the resemblance between puerperal and uræmic convulsions, and gave his opinion that "true eclampsia occurs only in women suffering from albuminuria." In 1857 Karl Braun, of Vienna, published his classical "*Lehrbuch der Geburtshilfe*," and ever since that time the exhaustive chapters on puerperal convulsions contained in that work have been the well whence author after author has drawn his modicum of information. I am not aware that a second edition of this work has been published, so that I do not know how far his present views agree with those expressed in 1857. We may presume, however, that they have not altered materially, for his colleague, Professor Späth, during the course of a clinical lecture in the early part of last year on a case of puerperal eclampsia, mentioned no other views than those expressed by Braun in 1857, and said that "the views of gynecologists as to the origin of convulsions were still hazy;" whilst Braun himself, in a still more recent lecture on a case of albuminuria with dropsy and gangrene of the labia (but without convulsions) makes no mention of any new opinions. We may say, then, that the teaching for the last quarter of a century has been that in the vast majority of cases so-called puerperal convulsions are accompanied by albumen in the urine of the patient, and that this albumen stands in some obscure causal relation to the convulsions. I need not mention the names of many writers. Braun, on page 458 of his work, calls eclampsia "only a partial symptom of another disease" (*nur Theilerscheinung einer anderweitigen Krankheit*). On page 465 he says: "Several years ago I came to the conclusion that acute Bright's disease and uræmic intoxication of the blood are the cause, and not the effect, of the eclampsia." Frerichs followed Braun, and having discovered carbonate of ammonia in the blood of a patient suffering from puerperal convulsions, he concluded that the eclampsia was caused by the carbonate of ammonia, and that this originated in decomposition within the blood of retained urea. Braun himself seems to have accepted this theory in part, and, acting on it, treated sixteen consecutive cases with acids and chloroform, and in every case with success. Murphy, of Sunderland, in an able paper on the subject, goes so far as to make albuminuria the pathognomonic symptom of the disease, and to exclude from the category all those cases in which albumen cannot be discovered. Lusk says that it is the renal insufficiency,

(a) Read before the Liverpool Medical Institute, Apr 2, 1883

and not the albuminuria, that is the cause of the convulsions, and seems to argue from the convulsions, a necessary renal insufficiency as the cause of them. Leishman under the term includes all cases of convulsions occurring during pregnancy, labour, and after delivery. He says: "Epilepsy is to be distinguished partly by the symptoms, but more particularly and conclusively by the absence of albumen in the urine. With rare exceptions, then, puerperal eclampsia may be looked upon as being essentially connected with uræmic poisoning, which again is associated with, or dependent upon, an albuminous condition of the urine."

Galabin saw 37 cases, and examined the urine in 22, finding albumen in all but one. In 3 out of the 21, however, the albumen was only found after the convulsions commenced.

According to the generally-accepted view, then, the sequence of events in puerperal convulsions is as follows:—

1. Pregnancy; 2. Pressure on the renal veins by the gravid uterus; 3. Parenchymatous nephritis (acute Bright's disease of Braun); 4. Uræmia, originating in some obscure manner (5) the convulsions; but whether by carbonate of ammonia poisoning, or by hydræmia, or œdema, or by retention of the general urinary excretory products, has never been settled to the satisfaction of all parties.

From the time of Braun's first publication, however, there have always been opponents to the uræmic theory of convulsions, men who have been quick to detect its weak points, and to seize hold of any fact that might be made to tell against it. Such a man was Seyfert, of Prague, the director of a huge lying-in hospital in that city. Lusk tells us that he opposed the uræmic theory on the ground of the following facts, or supposed facts:—

1. That convulsion may occur without albuminuria; 2. That albuminuria is in many cases the effect, and not the cause; 3. That in many fatal cases the kidney lesions were absent or wholly insignificant; 4. That convulsions are rare in chronic Bright's disease that has existed prior to pregnancy; 5. That in true uræmia, such as is necessarily produced by the suppression of urine, when the ureters are invaded, convulsions do not occur. Dr. Lusk very pertinently replies to the first proposition that it is the renal insufficiency or incompetency, and not the albuminuria, that is the cause of the convulsions. It is now recognised on nearly all sides that convulsions may and do occur without albuminuria; Dr. Lusk even goes further, and acknowledges puerperal convulsions without uræmia or renal incompetency: "Without uræmia puerperal irritation can provoke eclampsia." Murphy, of Sunderland, and Leishman, on the other hand, get rid of this objection (the first of Seyfert) by declining to acknowledge convulsions as puerperal unless they are accompanied by albuminuria. The latter calls these cases epileptic, and tells us that "the absence of albumen will enable us without difficulty to discriminate," i.e., between puerperal convulsions and epilepsy. Notwithstanding that he has shown us a royal or easy method of distinguishing between two diseases with somewhat similar symptoms, caution comes into play, and he finds it advisable to hedge a little. He says "no one can take a clear and comprehensive view of the pathology" of the subject "who does not freely admit that there are cases in which no uræmic poison exists." He first tells us that we can distinguish epilepsy from puerperal convulsions by the absence of albuminuria in the former, and next that puerperal convulsions can occur not only without albuminuria, but without uræmia, for albuminuria is of course nothing at all if it is not a symptom of an entirely distinct morbid condition—uræmia.

Playfair, who does not seem at all wedded to the uræmia theory, says: "It may be taken as proved that albuminuria is by no means necessarily accompanied by eclampsia. Cases were observed in which the albumen only appeared after the convulsion, and in these it was evident that the retention of urinary elements could not have been the cause of the attack." He goes on to quote from Braxton Hicks, that the two are almost invariably combined, and that the

nearly simultaneous appearance of the two, albuminuria and convulsions, must be explained in one of three ways:—

1. That the convulsion is the cause of the nephritis.
2. That the two are produced by the same cause—viz., some detrimental ingredient in the blood.
3. That the highly congested venous condition induced by spasm of the glottis is able to produce the kidney complication.

After considering the remainder of Seyfert's objections to the uræmic theory, I shall return for a moment to Playfair and Hicks.

Seyfert's second objection is nearly identical with Hicks' explanations Nos. 1 and 3—viz., that the convulsion is in many cases the cause, and not the effect.

Believing that puerperal convulsions and epilepsy spring from essentially the same causes, I have endeavoured to learn whether epilepsy is ever the cause of albuminuria. Saundby (a) examined the urine of a great many epileptics, both before and after the fits, and concluded that the attacks did not cause albuminuria. Professor Fiori, of the University of Cagliari, in a great number of epileptics, not only met with albumen, but hyaline cylinders and sugar. It was found also in animals rendered epileptic by Faradisation. He says, however, that the excretion of albumen was only transitory, and limited to the first moments after the attacks. (b) Klewdgen (c) examined the urine in 36 male and 21 female epileptics, always within four hours of an attack, and found albumen. In many cases the reaction was very slight, and only rarely was there any deposit. He soon extended his researches to the attendants, and, singularly enough, found traces of albumen in their urine, and finally concluded that there is nothing remarkable in post-epileptic urine. It appears to me that Fiori's statements require revision. They should either be confirmed or contradicted authoritatively. At present the statements of the three inquirers as to whether convulsions can produce albuminuria are contradictory, but I think the evidence upon the whole points to the conclusion that they cannot.

The third and fourth objections of Seyfert—viz., that in many fatal cases the kidney lesions were absent or wholly insignificant, and that convulsions are rare in chronic Bright's disease that has existed prior to pregnancy—are substantial ones, and are valid arguments against the uræmic theory. The fifth is also a valid one—viz., that in true uræmia, such as is necessarily produced by the suppression of urine when the ureters are invaded, convulsions do not occur. Cornil and Ranvier confirm the truth of this statement in an emphatic manner, and say that in no instance had convulsions taken place. I myself am able to verify this statement, or, to put it more correctly, in fatal cases of uterine cancer in which I have had reason to suspect occlusion of the ureters to be the immediate cause of death, although I have sought for evidence of uræmic convulsions, I have never been able to discover any. If, then, such complete retention of the urinary constituents as must of necessity exist in these cases fails *per se* to produce convulsions, it seems tolerably certain that some other factor is necessary for their production.

Dr. Hick's second alternative explanation of the nearly simultaneous appearance of convulsions and albumen may possibly be correct, but if it is it will negative the statement of Playfair to the effect that "retention of urinary elements could not have been the cause of the attack," for, as will be shown, there may be retention of urinary elements and no albuminuria. As I have already stated Lusk says it is not the albuminuria but the renal insufficiency that is the cause of the attack. We have heard from Dr. Andrew Clark of the baneful effects of renal incompetency without albuminuria. Israel, of Berlin, stated recently (d) that uræmia might arise without albuminuria and without nephritis, in consequence of the kidney not being able to do the increased work

(a) *Med. Times and Gazette*, Oct. 14, 1882.

(d) *Berliner Klin. Wochenschrift*, Nov. 20, 1882.

thrown upon it by the pregnancy. He experimented on rabbits and learned that by gradually accustoming them to the injection of urinary constituents they could bear the introduction of a large quantity without injurious consequences, but that if he injected similar large quantities into animals not previously prepared death rapidly resulted. He does not say, however, that death was preceded by convulsions. These experiments prove only that large quantities of urinary constituents suddenly thrown into an unprepared animal cause death and not, as he would claim, that they produce convulsions.

Now after all that has been said I am prepared to admit that, in the great majority of cases of puerperal eclampsia, urinary constituents in the blood play the part of contributories to the eclampsia, but I cannot accept the theory that they are the sole cause, and in this I follow Playfair as against most writers.

It is now necessary to inquire how the albumen gets into the blood, and what is the condition of the kidney in the albuminuria of pregnancy. Is there a real parenchymatous nephritis, as those who believe with Braun and Bartels affirm there is? Most probably not.

Dr. Angus McDonald published a remarkable paper on this subject, (a) in which he described the kidneys in a fatal case. To his surprise, no parenchymatous nephritis was present, as he had expected it to be. He says: "The kidneys were quite different from anything I have ever seen in acute renal disease. The sole change was apparently degeneration of the tubular epithelium." In Germany the condition of the kidney under these circumstances has also been noticed to be different from the form met with in acute Bright's disease. The condition is so marked that it has been designated by Leyden "the kidney of pregnancy" (*Schwangerschaftsnier*). Halbertsma, of Utrecht, denies that the condition is one of nephritis. Dr. Hiller, a German staff-surgeon, reports the autopsy of a fatal case, and says that there was no sign of any change in the interstitial structure of the kidney. Dr. Flaischlen, of Berlin, (b) gives the differential diagnosis between acute morbus Brightii and the kidney of pregnancy, although he acknowledges that it is not always easy to establish this with certainty. In the latter (kidney of pregnancy), according to him, hæmaturia is not present, the pulse is not so hard and incompressible as in acute nephritis, whilst the presence of fat corpuscles in the urine is a characteristic of the affection. The pathological change is a degeneration of the epithelium of the glomeruli.

Thus we have a series of original investigators who now deny that the condition of the kidney met with in the albuminuria of pregnancy and labour is ever acute Bright's disease, and assert that it is one of simple degeneration of renal epithelium. These investigators, as I have shown, are M'Donald, Leyden, Hiller, Halbertsma, and Flaischlen.

(To be continued.)

France.

[FROM OUR SPECIAL CORRESPONDENT.]

STRANGULATED HERNIA.—The treatment of strangulated hernia by subcutaneous injections of morphia is giving all the success vouches for it by Dr. Phillippe, who first brought it before the notice of the profession. The facts related by him caused others to try the experiment, and last year M. le Dentu brought it before the Société de Chirurgie in a report in which he expressed himself as favourable to the method when employed in recent cases. In a contrary case the success would be doubtful. M. Fleury, of Clermont Ferrand,

has just published two cases of strangulated hernia in his service in the hospital treated by subcutaneous injections of morphia with one of complete success. One case was that of a man who came to the hospital with abdominal hernia. The patient was in a very serious condition and refused all idea of operation. The morphia was injected twice, and the tumour was able to be reduced one-half, but no more, and the man, persisting in his refusal, in spite of the grave symptoms, sank the next day. The second case was that of a woman aged sixty-eight, who entered the hospital with a strangulated crural hernia. Simple taxis was tried, but failed, and morphia was injected, followed again by taxis, but still the tumour resisted. Ether spray was made to play on it with no better success. The patient was then put into a bath, where she remained two hours with a like result. A second injection of morphia was made as a last resource before operating: this time the alkaloid threw the patient into a kind of stupor like that produced by chloroform, and the muscles being entirely relaxed, the taxis was recommenced, and in five minutes of manipulation the tumour receded with its characteristic *bruit*. The woman left the hospital two days afterwards. To country practitioners this method of obtaining the reduction of strangulated hernia when other means fail must be a great boon, as the operation is of the simplest, and no aid is required.

TREATMENT OF MENINGITIS WITH IODIDE OF POTASSIUM.—Dr. Vovard, of Bordeaux, has published a series of cases of meningitis treated very successfully with iodide of potassium internally and croton oil externally. The oil—the head of the child being previously shaven—was laid on with a brush and the head covered with a bonnet of oil silk, which prevented the absorption of the oil by the pillow. The croton tiglium was renewed three times a day until an abundant suppuration took place, and then an irritating ointment was applied, which kept it up for several days. The cases cured by this means never suffered a relapse.

TYPHOID FEVER.—The discussion on typhoid fever which occupied the Académie de Médecine for the last six months was closed definitely by M. Fauvel in a long discourse on the cause of the affection. He commenced by saying that the doctrine of microbes was far from being proved, as they have not yet been discovered. According to M. Fauvel, typhoid fever is a malady *sui generis*, developed from a specific germ, transmissible, and which confers on those who have had it once immunity in the future. In France it is seen under two forms—the endemic in the large towns, the epidemic in the small localities. Overcrowding, insalubrity, contaminated water, drains, cess-pools, &c., do not engender the specific principle of typhoid fever; but all these conditions together united in the habitations of the large towns contribute powerfully to its propagation and gravity. In the small localities where the disease is epidemic the cause will be found in importation. Such was the doctrine exposed by M. Fauvel. The question will naturally be asked—What are the results of this long discussion in which the first lights of the Académie took part and freely expressed their views? I am afraid the answer will be rather disappointing, although the speeches have been very brilliant, and a great deal of science and talent has been expended. Many excellent and practical things have been said, different points in the evolution of the affection have been discussed and cleared up. Some of the phenomena, such as hyperæmia, received worthy attention; and I have no doubt that many will benefit by the *ensemble* of the views of the *savants* members. But if the question were asked—What is the cause of typhoid fever? according

(a) *Medical Times and Gazette*, 1880, vol. 1., p. 375.

(b) *Zeltseh. für Gynækol. und Geburtsh.*, Bd. viii., H. 2.

to the Academie, the answer would be very embarrassing, as it would still more if the treatment were asked. The result, as has been already said, is disappointing, for great things were expected; but, at any rate, it must be confessed that if there were many men of many minds each one was sincere in his convictions, and the desire of every member was to benefit by his experience not only his *cofreres* but the public at large, and so endeavour to mitigate, if not stamp out a disease, that has made so many yearly victims. As a result of the indefatigable devotion of the medical men attached to the hospitals in the recent epidemic, it may be mentioned that the mortality was kept well within the limits, rarely exceeding 14°.

At the Société de Chirurgie M. Verneuil gave his opinion as to the treatment to be followed in artero-veinous aneurism, which was that of tying the vessels above and below the sac. Contrary to the opinion of M. Reclus, he thought that it would be preferable not to open the sac. Recently he had a case in which he opened the sac, and a lymphatitis followed; and it was with great difficulty the patient recovered. Another member read a paper on bone suture in transverse fracture of the patellar. He had practised the operation on a patient, aged thirty-four, of a strong constitution, who in wishing to stop a run-away horse received a kick on the left knee, and the patella was broken transversely. Not being able to unite the fragments, suture of the bones was decided upon; and for that purpose the articulation was laid open under antiseptic precautions. A silver wire was passed between the two fragments, and the wound closed; the limb was fixed in a starched bandage. The result was highly satisfactory. In four weeks the patient could walk, and in six weeks he was about as usual. The author was able to collect nineteen cases in which the same practice was followed without one failure.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 11TH.

The President, ANDREW CLARK, M.D., LL.D., in the Chair.

DR. OLIVER, of Harrogate, read a communication on a
NEW TEST PAPER FOR ALBUMEN,

and demonstrated the reactions obtained by several experiments.

EXAMPLES OF THE TWO CLASSES OF CASES IN WHICH CEREBRAL ABSCESS, MENINGITIS, OR PYEMIA ORIGINATES IN DISEASE OF THE EAR.

Mr. DALBY read notes of eight cases in which suppuration within the tympanum had ended fatally. They were selected to show how, by the consideration of a large number of cases, they might be divided into two very distinct classes. In the first class were those in which a person apparently in good health, with both tympanic membranes entire, is attacked by acute inflammation of the tympanic cavity, ending in rupture of the membrane and a discharge from the ear. Within a period to be counted by days he or she has rigors, and in due course the usual symptoms and endings of meningitis, cerebral abscess, or pyemia. In the second class, before any serious complications arise, perforations have existed for many years, attended either continuously or at different times by a purulent discharge; and these might again be sub-divided into those in which the bone forming the tympanic cavity is diseased and those in which it is not. The questions which were discussed in this paper were as follows:—(1) Can it be predicted of any case in an early stage of its history that the probabilities are in favour of a fatal termination? (2) What are the local conditions of the ear,

or the symptoms which would point to such a conclusion? (3) Should any especial precautions be taken? (4) Is there any treatment of a local kind that should be employed as a protecting influence? (5) Is there any treatment which is often employed in perforations that should be especially avoided? From a consideration of these cases, as well as of many others which had come under the notice of the writer, he maintained that certain conclusions might fairly be drawn from them; at any rate, that although the subject of any perforation of the membrane was in some degree of peril, that those in which the bone was diseased were in greater danger than those in which it was not. It was not difficult to determine whether the bone was affected: a careful examination with the probe under reflected light, exuberant granulations and bony *sebor* would decide the question. At the same time, it should be remembered that a considerable area of diseased bone in the tympanic cavity is quite compatible with long life, and this is especially the case if the patient has learned to manage the ear by scrupulous cleanliness, and by some sort of protective pad which would keep the external air from the lining membrane of the tympanum. Influences which may lead to a fatal ending are the entrance of sea water into the ear, and the use of strong mineral astringents. Thus, in estimating the probabilities of a long life for persons with perforations, their habitual discretion forms a distinct element as to their chances, and this might well be kept in view by insurance companies. Other points for consideration are the urgent necessity of removing a polypus if it prevent the egress of discharge from the tympanum; the important bearing of head pains, whether occurring either at the commencement of the inflammation of the middle ear, or at a later period; the importance of, in recent cases, great profusion of discharge, attended with feelings of giddiness.

Mr. WARRINGTON HAWARD said it was useful to be reminded of the possible gravity which might attend the existence of ear-discharges, and it was important to consider how far the surgeon's power to relieve might extend, especially in the class of cases so commonly met with among children. As a rule, however, in dangerous cases, advice was sought at too late a period for fatal issues to be averted. The existence of profuse discharge, with necrosed bone and internal granulations, raised the question, What course ought to be pursued in respect to this condition? It was obvious that should a polypus exist, its removal would be imperatively demanded; but whether, otherwise, operation would facilitate evacuation of contained pus, became a most important point for decision. It had been shown that even simple lotions might be powerful to initiate most dangerous consequences. Profuse discharge, however, should in any case be assisted to escape, and hence the cleansing of the tympanum through perforations into the mastoid cells formed a method of proceeding which called for anxious consideration. Even, however, when such treatment was justified by the condition of the case, it might be too late to pursue it successfully, and hence the most important point connected with the whole subject of treatment in such cases resolved itself into this one of creating additional channels of escape for contained purulent deposit.

Mr. JESSETT asked if post-mortem examination of the cases recorded by Mr. Dalby had been made? The evidence afforded by their history pointed to pyemia. The speaker was recently called to see a girl who had profuse discharge from the ear. The skin over the mastoid region was brawny; there was a temperature amounting to as high as 108° F., and profuse sweating. The child died, and on post-mortem examination necrosis of the petrous bone was discovered, and at one point communication through to the cavernous sinus was opened up.

Dr. DE HAVILAND HALL suggested the propriety of excluding such cases as were referred to entirely from the lives accepted by medical examiners to insurance offices.

Dr. R. J. LEE considered it was essential, from a practical point of view, accurately to decide on the real nature of such cases. In one case seen by him some time ago a child under treatment for typhoid fever was found to suffer from cerebral mischief, and on inquiry he discovered that two months previously she had discharged a quantity of matter from the ear. He perforated the mastoid region, with the result that pus was evacuated, but death supervened. In another case, that of a boy who had fallen from a bicycle, opening into the mastoid cells was suggested by old perforations found in the tympanic membrane, and two days after the

operation pus flowed freely, general improvement of the patient taking place thenceforward. Dr. Lee was of opinion that the operation was called for when no harm was likely to arise from its performance, and if beneficial results were, as in the case he related, to be expected as its result.

Dr. MAHOMED observed that aural surgeons encountered very large numbers of patients with ear discharges who did not suffer the terrible consequences described. Exceptional cases would naturally create alarm, but their existence should not lead to forgetfulness of the fact that many less dangerous instances of the affection were met with. His own experience did not endorse Mr. Haward's conclusion that bad cases come under treatment too late for good to result to them. He instanced the case of a boy from whose ear a profuse discharge was passing, and in whose condition much improvement was shown as a result of trephining the mastoid; and similar treatment produced similar good effects in other cases also. In another and recent case—that of a man with aural vertigo, no perforation, and who died from suppurative meningitis—nothing was found in the state of the ear on post-mortem examination to account for the result.

Dr. RODGERS quoted his experience of the good results obtained after treatment of ear diseases by means of leeching and counter-irritation, and by application of lotions, even in severe cases of perforation and profuse discharge. He had witnessed many instances in which persons rejected from Civil Service employment on account of ear disease preserved good health, notwithstanding, for many years; and he would not be inclined to refuse acceptance for insurance of such patients as had for a long time been troubled with recurrent discharge.

Dr. ANDREW CLARK suggested that it would be highly valuable if Mr. Dalby would give the percentage of fatal cases met with, and also if he would describe the proper methods to pursue in treatment of such diseases.

Mr. DALBY deprecated any wish on his part to imply that perforation was frequently fatal. All practitioners must necessarily be acquainted with numbers of persons who, though possessing perforated tympana, yet enjoyed long life. It was difficult to give the proportion of fatal cases; his own experience included eight deaths, all in private practice, extending from 1874 to 1883, and in addition four others, in which no post-mortem was possible. Probably death occurred after perforation in one out of two or three thousand cases. He would not dream of rejecting every case of perforation as unfit for insurance. Those persons so afflicted who were duly careful in regard to cleanliness and protection he would accept; but would recommend the imposition of higher premiums on such as were not apparently alive to the necessity for great precautions on their own account. Post-mortem examinations had been made in all but one of the cases recorded. He recommended opening into the mastoid cells in cases where profuse discharge and great head pain were associated with the production of pain on pressure over the mastoid eminence. Leeches were useful in some instances, but not in cases like those narrated in his paper.

Mr. C. HIGGINS and Mr. G. NETTLESHIP on

A CASE OF MORPHEA IN THE REGION OF THE FIFTH NERVE WITH PARALYSIS OF THE INTRA-OCULAR BRANCHES OF THE THIRD.

The subject of this case was a married woman, *æt.* 35, who applied to Mr. Nettleship in November, 1880, with mydriasis and partial cycloplegia of the left eye, with evidence of some dilatation of the retinal vessels and thickening of the coats of the retinal veins, and dilatation both of those vessels and the arteries. She also had single patches of ivory-white morphea on the corresponding temple, side of nose, and upper lip, and a similar but less characteristic change in the skin of the forehead and front of the scalp on the same side, with thinning of the hair. The eye symptoms were of three months' duration; she had not discovered the skin changes. She was out of health from recent parturition and old uterine troubles. There was no proof of syphilis. She used eserine, and took various medicines, including iodide and arsenic, for a year, and then went to Guy's Hospital, where, under Mr. Higgins's care, she has continued the same local treatment and taken iodide of potassium and mercury. The symptoms in the left eye are unaltered, except temporarily, by the eserine drops; the healthy skin affected by the morphea has become partially atrophic, and the hair on

the affected area has nearly all fallen. Latterly there have been threatenings of an onset of the same disease on the right side of the face and in the right eye, but it is not at present declared. During the course of the case there has been some eczema behind the ear and on the palm on the same side as the morphea. The authors point out that, whilst the morphea is strictly confined to territories supplied by the first and second divisions of the fifth nerve, the eye symptoms point clearly to affection of the branches of the third to the interior of the eyeball; and they observe that in this respect the case may be compared with those cases of herpes of the fifth in which the third or other motor nerves are also affected.

Mr. HIGGINS added that, having seen the patient since the paper was written, he found that an additional white patch had appeared over the angle of the left scapula.

Dr. HADDEN asked if any pronounced loss of sensation had been observed? He was inclined to regard the existence of further patches as described by Mr. Higgins as evidence of more diffused cerebral or spinal change.

Mr. NETTLESHIP replied that no such impairment of sensation had been noticed, except over the patch on the temple.

Dr. STEPHEN MACKENZIE exhibited a male patient the subject of myxedema, and the following cases were also shown:—Congenital deficiency of femur; Sclerema neonatorum; and Lateral curvature.

ACADEMY OF MEDICINE IN IRELAND.
MEDICAL SECTION.

The Medical Section met at the College of Physicians, Friday evening, April 20th; Dr. WILLIAM MOORE, President, in the chair.

Dr. MONTGOMERY, Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

SPECIMEN.

Dr. McSWINEY.—Thoracic aneurism.

THE THERAPEUTIC VALUE OF NERVE STRETCHING.

Mr. STOKES read a paper on the therapeutic value of nerve stretching in *tabes dorsalis*. He commenced by pointing out that the evidence afforded by the cases of *tabes dorsalis* treated by nerve stretching indicated the fact that relief for some of the most distressing symptoms of that disease may, if the operation be performed sufficiently early, be anticipated. He considered that the absence of a physiological explanation as to how the operation acts is no reason for its rejection, and gave instances of other operative procedure, of which the *modus operandi* is, as yet, unexplained. The particulars of two well-marked examples of the disease treated by him, in one of which he stretched the sciatic nerve on one side, and in the other on both sides, were then given. Although the operations were not followed by any signal improvement in motor power, the results in other respects, as regards relief from lightning pains, vesical irritability and return of sensibility in certain regions of anaesthesia were satisfactory and encouraging. The views of various writers on the effects of stretching on the nerves were discussed, and those of Ceccherelli shown to be at variance with the results obtained in the author's cases, and also with the experience of Dr. Brown Séquard. Then Mr. Stokes discussed the importance of estimating accurately the amount of force that should be used, and was of opinion that a very moderate amount is sufficient to obtain the desired therapeutic results. He also stated his belief that many of the recorded failures of the operation were to be attributed to the employment by the surgeon of an undue amount of force. He advocated the use of an electric cord and dynamometer in nerve stretching, and believed that in the case of the larger nerves a force of about 10 lbs. would be found sufficient. Although a satisfactory physiological explanation as to how nerve stretching produces the results observed was still to be obtained, we were not wholly in the dark. He quoted Dr. Brown Séquard and Dr. Charlton Bastian, to show that after the operation a certain amount of vaso-paralysis is produced, resulting in vascularity and increased temperature of the part, and that the improvement which occasionally follows the operation is probably connected with these phenomena.

The PRESIDENT did not see why they should pass over nerve stretching merely because they did not understand the

rationale of the treatment. He thought the procedure would apply to nervous functional affections such as sciatica.

Dr. DUFFY said there was no doubt the operation gave a certain amount of relief to some of the distressing symptoms of the disease. Ceccherelli in giving an analysis of 100 cases of nerve stretching for various conditions, had described certain pathological changes when the operation had been followed by extravasations, or regenerative changes having taken place in the cord itself. In favour of this view, nerve stretching on one side of the body might relieve symptoms referable to both sides.

Dr. C. J. NIXON considered that the operation of nerve stretching in this disease should only be used in desperate cases, after all other means of giving relief had failed. He thought it a very doubtful point what amount of traction could safely be made on the cord.

Dr. FINNEY asked what was the right time at which the operation should be performed. He referred to the frontal nerve having been stretched in cases of facial neuralgia.

Dr. H. KENNEDY thought that slightly pinching the nerve and thus conveying irritation that could not injure its substance, might have a beneficial effect.

Dr. COBLEY considered the operation a most serious one to perform, and one to be approached with the utmost carefulness. In some cases of stretching the sciatic nerve, the cord answering mechanically to the stretch, would be moved as far as the cervical vertebrae. In the case of sciatica to which he applied it the nerve was affected with neuritis. The next day severe symptoms arose indicating that, although the force used was not great, it had effected serious changes in the cord. These symptoms disappeared after forty-eight hours. Two months had now elapsed since the operation with complete absence of sciatic pain.

Mr. STOKES, in reply, said that in Ceccherelli's cases undue violence must have been used. He could not lay down any rule as to the time at which the operation should be performed, but probably the earlier the better.

THORACIC ANEURISM.

Dr. McSWINEY read the notes of a fatal case of thoracic aneurism occurring in a sailor who had worked at his employment to within one month of his death. The aneurism was not diagnosed during life, as there were no signs or symptoms present specially characteristic of the disease. The man was supposed to have got cold from exposure during bad weather. He had cough, bronchial râles, and pain in the region of the heart. Physical examination threw no light on the nature of the case. The patient expectorated nine or ten ounces of bright-red blood, and died in a few hours afterwards. *Post-mortem 20 hours after death.*—The aneurism springs from the posterior and outer aspect of the descending portion of the arch of the aorta, and projects into the upper and inner part of the left division of the thorax, a portion extending across the vertebral column, eroding the bodies of the third, fourth, fifth, and the upper part of the sixth dorsal vertebrae, and lying in the upper and inner portion of the right division of the thorax. The third and fourth ribs on the left side have been eroded, and the tumour has passed backwards between them a short distance. The entrance into the aneurism is circular, and about as large as a sixpence; and a quarter of an inch below it a little pouch is formed in the site of the origins of the first pair of intercostal arteries. This is evidently the beginning of a second aneurism, the aorta being in this position very much diseased. The arch and thoracic portion of the aorta are atheromatous, as are all the valves of the heart in varying degrees. The bronchi and œsophagus do not show any sign of pressure. The thoracic duct could not be found, but large lymphatic vessels connected with glands lying at the sides of the dorsal vertebrae are to be seen. The sac is filled with laminated fibrine, and was covered with a quantity of tough matted tissue. The aneurism was, therefore, diffused. The recurrent laryngeal nerve was not to be found in the specimen. A few fibrous strings are to be seen at the upper portion of the pericardium, but no signs of pericarditis on any other portion of the pericardium. The lower lobe of the left lung at its superior posterior part has become adherent to the aneurism, which has here burst into it. There is a cavity in the central portion of the external part of the lobe which was covered only by pleura. The costal pleura is thickened on both sides, and on that portion nearest the tumour the deposited lymph has undergone fatty degeneration.

The PRESIDENT could not agree that symptoms were quite absent.

Dr. FINNEY drew attention to the absence of hypertrophy of the left ventricle, notwithstanding the size of the aneurism, which confirmed Stokes's observation on this point.

Dr. C. J. NIXON related a similar case of fatal aneurism, in which the only symptoms present during life were those of severe bronchitis.

Dr. HENRY KENNEDY having made some remarks on the case,

The Section adjourned.

THE UNQUALIFIED ASSISTANT SYSTEM AND THE ILLEGAL SIGNING OF DEATH CERTIFICATES.

(Continued from page 425.)

THE RISE AND PROGRESS OF THE SYSTEM OF EMPLOYING ASSISTANTS.—(Continued.)

AN unqualified assistant's end is often very sad. In Halifax a late leading practitioner employed one for twenty years. His successor strongly disapproves of unqualified assistants, and the poor discarded drudge died lately in a county lunatic asylum. If he becomes paralysed or otherwise crippled he has, from the smallness of his salary, no savings to fall back upon, and is ineligible for aid from medical charities. There is one in Yorkshire who is "eking out a miserable living by cadding and barrowing." Others are thrust by misery into utter recklessness of most unclean living, despair, and suicide. It may seem unjust to attribute such awful results to the occupation we are speaking of; yet, surely, it is something more than a coincidence when a magistrate in the county of Durham, a barrister, informs me that four unqualified assistants, under one master, consecutively so ended their lives, while from another source we hear of a fifth case of suicide from drink and opium in a neighbouring colliery district.

The despair is not, in all instances, attributable to alcoholism. It may be an erroneous form of repentance. An assistant who had imperilled a patient's life by omitting to notice a strangulated hernia, was so pained by the oversight that his principal tells us he never saw equal remorse.

An unqualified assistant is often preferred by masters from an idea that he is less likely than a registered man to set up as an established rival, and to convey their patients to himself. In short, it is their interest to keep him out of registration, and selfish masters will throw impediments in the way of his attending a medical school. The ground of the preference is questionable, for, as a matter of fact, he often does start an illegal practice; and with a qualified man the danger is easily provided against by a formal agreement.

Economy is sometimes alleged as a motive of the preference alluded to; but in reality the pay of the two classes is about the same, according to the statement of a firm largely engaged in the transfer of practices. In the east of Yorkshire "an assistant, though unqualified, if he is sober, reliable, and gentlemanly in his habits, will of course command a higher salary than an incompetent qualified man. Sometimes an assistant who manages a branch gets a salary with a percentage on the profits also." In the metropolitan counties the salary ranges from £100 to £200 a year; a surgeon in an agricultural district used to pay £150 for the management of a branch. In Lancashire we learn the usual income of an unqualified assistant, finding his own board and lodging, is £120; if he lives in his master's house, £85; besides this, he usually has 5s. for attending each labour. Where only half a young man's time is contracted for, and he is allowed to attend a hospital school when disengaged, less is given—not more than £45, and sometimes much less. At Halifax indoor unqualified assistants get only from £25 to £45 a year. A man who is sober, reliable, and gentlemanly in his habits, though unqualified, will command a higher salary than a dissolute and incompetent qualified person.

Unqualified assistants are described by gentlemen who have employed them as being less "raw" than their qualified colleagues, "especially in midwifery, the knowledge of prescribing and drugs." "They are better up in the practical details of surgery work." "They make themselves more acceptable to patients, and are better acquainted with the routine of work." They are handier and neater in dispensing and better accountants. In the use of forceps and

other instruments of midwifery they are more experienced. They extract teeth with greater facility, and their handwriting is more readable. "They are more economical of their principal's goods." "They can be made to occupy a more subordinate position as residents in the house." These accomplishments, however, do not necessarily make them competent to take charge of the sick; and, moreover, we would remark that, for the comparison to be a fair one, even in the particulars enumerated, it should be instituted between two men who have not been engaged in the employment previously, and should be repeated after they have been a few months at work and have got into the ways of the place. Besides, rawness has at least this recommendation, that it implies the absence of much to unlearn.

The personal character of the unqualified assistant is sometimes so good that he is respected even by those who disapprove of his existence. An instance is quoted (in a MS. biographical sketch of the unqualified assistants in a large town by one of the surgeons) of one who had attended upwards of 8,000 confinements under a succession of masters. When he died, old and poor, the medical men of the town subscribed to bury him.

The unqualified assistant is often popular among the working classes, inasmuch that they will condone even his evident neglect. On one occasion in Yorkshire an unqualified assistant, through carelessness, vaccinated several children with impure lymph, and all died of erysipelas. He was committed for trial on coroner's warrant, and the grand jury threw out the bill. The police surgeon who communicates the tale, and who performed the autopsies supposed to criminate the accused, was hissed through the streets, and his house stoned; while the unqualified assistant was met with a carriage, in which he was drawn home by the mob in triumph. A surgeon to large ironworks says:—"The most popular assistant (but not by any means the best) I ever had was an unqualified man, who was sought after by all sorts of people." Dr. R—, of R—, believes that "as a rule, clubs do not object to being attended by unqualified assistants. They don't know, and don't inquire, whether they are qualified or not; and if the assistant have plenty of assumption, they take for granted that he is, and address him as Dr. So-and-so accordingly." Another large employer of assistants says, "The climax was reached when a deputation from a neighbouring works (and a very large one) waited upon him (an unqualified assistant) and offered to secure him the appointment of surgeon about becoming vacant." It is not stated whether he has accepted the post. But if so, he would have a precedent in a colliery parish of 5,000 souls, where the appointed medical attendant is the unqualified nominal assistant to a registered practitioner resident in a city several miles away, who supplies death certificates. The vicar, who gives this information, adds that the appointments are made through the influence of the "viewers." And it is affirmed from another quarter that the influence of viewers is secured by giving gratuitous attendance on their families.

This popularity is partly due to skill and tact in the management of normal midwifery cases, of which instances have been already given. Some think an unqualified assistant is cheaper for the patient to employ, which is not the fact. And the price at which a man can get medical attendance for himself and family from a respectable club—viz., by a rate of 2d. or 3d. in the pound of his weekly wage, really puts all preference grounded on supposed cheapness beyond the pale of sympathy.

Something also is due to comradeship and familiarity with the working man, found in those who come from the lower strata of society into the ranks of unqualified assistants.

Another important factor in the preference shown is a distorted belief that towards the making of a good adviser inborn sagacity is of more value than school learning, which is thought to smother it, instead of nourishing it.

It is not to be expected that among operatives at present a distinction will be made between qualified and unqualified men in favour of the former. A colliery agent for large underground property in a district where assistants of both sorts are much employed by the medical men, says: "Had the men on the collieries of which I have the superintendence been dissatisfied with the assistants, I have no doubt I should frequently have had complaints about it (Sept. 6th, 1882). Another says (Sept. 7th, 1882): "As a mining engineer I have well on to 3,000 men and boys under my charge, and I have never heard of any complaint made about

the unqualified assistants. Whether or not this may have arisen owing to ignorance of the fact I cannot say; but I do know that in some cases the people prefer the assistant to the principal."

Yet, in spite of this, "there is a growing discontent in consequence of the education of the public and the revelations of various inquests. . . . In a few years a more educated body of operatives will not be content with a low-class practitioner like the *officier de santé*."

USES OF UNQUALIFIED ASSISTANTS.

The uses of an unqualified assistant, as set forth in the numerous advertisements recommending him—some using being of importance to one master, some to another—seem to be as follows:—

1. To see patients at his master's house under supervision, and to carry out in his master's absence treatment according to specific instructions given him in each case; to visit gratuitously the sick at their homes, and treat them according to his master's directions; to carry on the work of dispensaries and branches under similar restrictions.
2. To keep the books and bring into his employer all the cash he receives.
3. If his master is unavoidably unable to attend when called to a serious emergency, to procure (if possible) a neighbouring practitioner to supply his place for the nonce.
4. To extract the teeth of casual patients, and to act as midwife in labours under supervision.
5. To perform post-mortem examinations.
6. To dispense medicines to his master's patients only, and convey them to the patients' homes when necessary; if he be registered under the Pharmacy Act, he may also sell over the counter to casual customers; to clean out the surgery, wash the phials, keep the instruments in order, and the drugs in their proper places; to answer the summons of the surgery and night bell.
7. To drive his employer or himself; to ride on the round of distant visits; to groom the horses, saddle them, and put them up, where no one else can be found to do it for him; and generally to perform the duties of a "gentleman help," that is to say, duties which a poor gentleman does not hesitate to perform for himself in cases of need. He is the living representative of the "squire" or "page" of the middle ages, of the "apprentice" of the last generation.

In all these foregoing points the use of the assistantship is almost entirely to the advantage of the master.

8. The beneficial use of this system to the unqualified assistant himself is that it cheaply offers him a chance of picking up the art of midwifery, of preparing and sending out medicines, of bandaging, and of performing minor operations, and of acquiring tact and readiness in dealing with patients. He also gains a knowledge of bookkeeping. Often he may obtain leisure to attend lectures at a medical school, and thus become qualified; and occasionally he may be favoured with real clinical instruction in a method which is best exhibited in the following extract from a letter in the possession of the committee, written by a gentleman endowed with a high sense of honour, and formerly a lecturer at a medical school:—"When I took the practice at — there was an unqualified assistant whom I employed for ten or eleven months afterwards. He had had nearly the full curriculum. A case was visited by him for the first time in my absence, and died speedily. I certified it, stating in the body of the certificate that it had not been seen by me, as death so speedily ensued, leaving it to the registrar to say whether or no it was satisfactory. He deemed it so, and I heard no more of the matter. That was the only such case that I know personally. Other cases died under him, but I saw them again and again, and discussed treatment. He left me to complete his hospital work, and is now in practice qualified."

In such like instances, the benefit conferred is undoubted but a master with equal love for teaching and equal competency is rare. And it may also be remarked that he did not try an unqualified assistant again.

Of the above-named Uses some appear inconsistent with the

growing customs and regimen of our profession, and can, year by year, be more easily spared without inconvenience. Book-keeping (Use 2), for example, except of the lightest and simplest sort, need not be done by an assistant, for an accountant will periodically make up the accounts at less cost, and, in fact, is generally employed. Use 3 is provided for by the naming of a qualified *locum tenens*, as is required of parochial medical officers by the Local Government Board. Co-operation in this arrangement among the neighbouring practitioners is described by a correspondent working a large club practice with much administrative skill, yet finding time for social and intellectual relaxation. Use 5 is a doubtful one, for coroners at best will not accept the report of an unqualified man. Use 6 is annually of less and less importance. Modes of prescribing simpler than of old are adopted; manufacturing chemists make in great variety convenient and portable preparations, and the parcel post distributes them with speed and punctuality. So that dispensing is in most practices a light work, such as any lady may, and sometimes does, assist in without interference with her domestic duties. Use 7, again, is out of date, and, were it not for advertisements, might have been supposed extinct. Use 8 is so very much greater in the case of those who have completed their curriculum of systematic instruction, that the almost unanimous opinion of teachers is in favour of its postponement till after qualification.

Yet in such Uses there are involved, of necessity, no breaches of the laws of the country, of morality, or of honour. And in some peculiar practices, especially of a public character, it would be a great inconvenience to be debarred from them. To the bulk of the profession the anxieties entailed by the use of assistants, especially when unqualified, outweigh the advantages conferred; in the words of a prudent practitioner in the Potteries, "they are more plague than profit." And several of the uses readily degenerate into serious ABUSES.

ABUSES OF UNQUALIFIED ASSISTANTS.

The chief ABUSES of the employment of unqualified assistants by registered practitioners are reported by employers and employed to be the following:—

1. *Unqualified assistants are made agents in dishonourable pecuniary dealings.*

The use of an unqualified assistant is to act "as a stop-gap," according to a large employer of them, who has communicated valuable and well-considered information on the system. His duty is to his master, whose practice he prevents from suffering damage by the principal's absence. Nevertheless, there is credible reason for believing that many medical men do abuse the system by obtaining payment from patients for visits, and for advice, and for other services rendered by unqualified assistants. They have no equitable claim for such payment, and if they try to enforce it by law, their claim is not allowed. This appears clear from a case tried recently (November 4, 1882) at the City of London Court, in which an L.S.A. sought to recover £3 for services rendered to a patient mainly by his unqualified assistant. Judgment was given for the defendant, on the ground that those services could not be charged for. To charge for them, then, is to presume upon the ignorance or apathy of the public, and is a false pretence. Private practitioners can avoid doing so, by taking care to book only their own *bona fide* visits; but the medical officers of institutions similar to colliery clubs cannot help it, since they are paid in advance by salary, or by a rate on the workmen's wages. They contract to supply medical advice, and if they supply in its place that which is not medical advice in the eye of the law and the common sense of the profession, they are committing a fraud, as surely as a shop-keeper who knowingly substitutes brass for that which has been paid for as gold.

The money gained by the unqualified assistant for his services evidently does not of right belong to the principals. Yet they are credibly reported to receive it, and are described as going round to outlying dispensaries and branches in London to collect what they consider as *their* profits. So strongly are they impressed with a sense of proprietary right, that they look upon the retention by the unqualified assistants of these moneys as an "embezzlement." A correspondent who has suffered much from unqualified assistants, naively says of them, "Many who play their cards well embezzle a quarter, or a third part (perhaps more) of the

receipts"—as if the money belonged to the writer. A strange blunting of honourable feeling, which is in every sense "infamous conduct."

No legal technical meaning is in England attached to the word "infamous." It is to be taken in its current ethical sense, in which an essential feature is that the deed is done or the conduct pursued for the sake of gain.

"If we understand the meaning of words, it is *infamous* to commit a wicked action *for hire*." The sentence is Macaulay's and is intended to characterise a strictly legal but cruel act, the hiring out of British troops to a native prince for the ravaging of Rohilkund. A few pages further on, the writer uses the word again in speaking of Sir Elijah Impey's acceptance of the Chief Justiceship of Bengal, on the condition of holding his tongue. He is described as sitting on the bench "rich, quiet, and infamous." The citation is made not as implying that the cases are precisely the same as that of the employment of unqualified assistants, but simply as illustrative of the use of the word in ethics, and the inclusion of the idea of gain as essential to "infamy" in the instance now being considered.

At the same time, "infamy" admits of many degrees, and justice demands that it should be visited with many degrees of punishment. Moreover, it may be partially or wholly condoned by previous or future distinguished services or good conduct. It is, therefore, much to be wished that the Council should claim the power of restoring to the *Register* names erased from it, to enable them to graduate the punishment in proportion to the offence.

Efforts, usually successful, are made by the proper authorities to prevent sick paupers being entrusted to the care of unqualified assistants. It appears, by a letter read to the Council, August 7th, 1878, from the Local Government Board, that "it is specially provided by Article 199 of the General Consolidated Order, that every medical officer shall be bound to attend personally, as far as may be practicable, the poor persons entrusted to his care;" and, further, in Article 200, "that every medical officer shall, as soon as may be after his appointment, name to the Guardians some legally qualified medical practitioner to whom application for medicine or attendance may be made in the case of his absence from home, or other hindrance to his personal attendance, and who will apply the same at the cost of such medical officer, and the name and residence of every medical practitioner so named shall be forwarded by the clerk of the guardians to each relieving officer, and to the overseers of every parish in the district of such medical officer."

The Board attach much importance to a strict compliance with the foregoing regulations, and it is their invariable practice in any case brought under their notice to express their marked disapproval of the employment by a Poor-law medical officer of an unqualified assistant in the treatment of the sick poor entrusted to his care."

Perhaps these orders are sometimes evaded. At an inquest, reported in the *Standard* of November 24th, 1882, as being held at Islington, it was stated by a witness that "the parish doctor's assistant" attended his child. As he declined giving a certificate himself, it may be presumed he was unqualified. Also from a letter in the *Medical Press*, of May 24th, 1882, a case may be quoted where a medical officer selected by some country guardians gave as his main recommendation that he had three unqualified assistants in charge of branch practices, who would help him in his parochial duties. Still the intention of the Local Government Board is evident.

To be continued.)

NOT any deaths were referred last week to any of the principal zymotic diseases either in Wolverhampton or in Derby. The highest annual death-rates from whooping-cough were 1.4 in Plymouth, and 2.7 in Hull; from measles, 1.0 in Bristol, and 2.5 in Liverpool; from scarlet fever, 1.4 in Halifax, and 1.8 in Sheffield; and from "fever," 1.6 in Portsmouth and 1.8 in Birkenhead. The 18 deaths from diphtheria in the twenty-eight towns included 13 in London. Small-pox caused 4 deaths in Newcastle-upon-Tyne, 3 in London, one in Birmingham, one in Liverpool, and one in Leeds.

WEDNESDAY, MAY 23, 1883.

DAMAGES FOR DEFECTIVE DRAINAGE.

MR. COMMISSIONER KERR'S decision in the case of *Cook versus Elvin*, given on the 7th of May in the City of London Court, is one of very considerable importance to landlords and tenants. It distinctly affirms the principle that landlords are legally responsible for the ill effects arising out of defective drainage.

The plaintiff, a builder and contractor, sued the defendant, a widow, for the sum of £4 16s. 6d., said to be due on account of rent. The defendant brought forward a counter-claim for £10, basing the claim on two points—1st, for breach of contract, by which she agreed to pay an increased rental of £4 a year on condition that the house was made habitable; 2nd, for illness and loss sustained through the bad state of the drains. The Commissioner decided in favour of Mrs. Elvin in both cases, granting costs on the higher scale. He stated that he would have awarded a higher sum than the £10 had he been asked, because no one could calculate the injury to health at the time, and in the future, from living in an unsanitary house. He further remarked that it was high time that landlords were taught that property has its duties as well as its rights.

The importance of this decision cannot be questioned, neither do we think that sanitarians will feel inclined to quarrel with its justice. We see no reason that tenants should be burdened with the trouble and expense of keeping the drainage in a state of proper repair, or, in the first instance, of seeing that the drains are in con-

formity with the well-ascertained principles and laws of sanitary science. The rent demanded ought to guarantee that the house is in every way fit to live in without prejudice to the health of its occupants.

It is quite time that responsibility in the matter should be placed on the proper shoulders, and not to allow the present unsatisfactory condition of affairs to continue. Too often we find that want of proper attention to sanitary principles is allowed to continue until sickness and death compel the occupants of a house to inquire into and to take steps to remedy existing defects at their own cost, rather than await the tedious process of convincing a landlord that such steps are necessary.

It is not necessary to be a very old practitioner to become acquainted with the terrible mortality and amount of human suffering and misery that can be clearly traced to defective drainage. Examples the most glaring are continually cropping up under one's notice of offences against the laws of sanitation and their ill effects. There are few men in active practice who are not familiar with what may aptly be termed "the sewer gas tongue," which is nothing more than, so to speak, the initial and, as it were, chronic stage of the true typhoid tongue, presenting as it does a furred surface, prominent papillæ, and triangularly reddish tip. This condition of the tongue is accompanied by a want of tone in the system generally, deranged digestion, and a diminished power of resistance to intercurrent attacks. One has seen in families where such a condition of the tongue and digestive system has been steadily persistent one acute febrile affection follow the other, the changes being rung upon typhoid, diphtheria, recurring ulcerated sore-throats, scarlatina, measles, rôteln, and diarrhoeic attacks. The members of such families, also, show a vastly increased susceptibility to inflammatory thoracic attacks, such as pneumonia, bronchitis, and broncho-pneumonia, and very often we find the lung mischief terminating in the advanced stages and fatal ending of phthisis.

One has also seen the immediate, steady, and permanent improvement that has taken place in such families when at last the question of defective drainage has been inquired into, and the defects set right.

One horrible custom that at present exists should be at once forbidden, and that is, the leading a wide drain-pipe straight into the underground cellar from the main sewer; and that, too, without any decent attempt being made even to trap it. The architects and builders of such houses ought to be subject to indictment when guilty of making, or allowing such an arrangement to exist. It is almost as blameworthy as the act of the poisoner. Assuredly they are morally responsible for every death that occurs in such a house from zymotic disease.

Too much cannot be said or written on this subject. Few men have done more than Mr. Pridgin Teale, of Leeds, to place the subject of proper house drainage before the profession and the public generally in a clear and understandable light. His work (a) on the subject, diagrammatic, and profusely illustrated, both by drawings of the various possible defects, as observed in

(a) "Dangers to Health: a Pictorial Guide to Sanitary Defects."

actual instances that have fallen under his notice, and by the cases of illness that resulted where such defects were discovered, leaves nothing to be desired to carry conviction to the minds of all as to the vast importance of the subject. We think Mrs. Elvin has done good service in bringing the question of a landlord's liability for ill effects arising out of defective drainage to the test.

In future, thanks to Mr. Commissioner Kerr's good common-sense judgment, it will be impossible for landlords to shirk their responsibilities, and should they attempt to do so, it will be at the risk of their pockets, should damage be sustained through their negligence. In future, tenants will do well, when demanding to have their drainage seen to and set right, to warn their landlords that if nothing is done, and loss is sustained, they will hold them responsible. Members of the profession would do well carefully to record and forward for publication every instance of defective drainage that may come under their notice, more especially when coupled with deranged health in the case of the occupants of the house. Such records would make useful data upon which to frame further legislation, if necessary, as to the responsibilities and duties of house-property owners.

CONCEALMENT OF DISEASE UNDER COMPULSORY NOTIFICATION.

WHEN we recently criticised the proposal to compel the physician to notify to the sanitary authority all the cases of infective disease which came within his notice we endeavoured to show that the natural tendency and immediate result of stringent enforcement of sanitary precautions is concealment of disease, and that it is reasonably to be expected that the physician will, with a view to secrecy, be habitually excluded from the early treatment of infective cases if he be made the agent for putting these sanitary precautions in force.

That our anticipation of the effect of such law is justified by experience, and that concealment of infection is rife in towns where the law is in force, is capable of proof by the testimony of physicians engaged in the treatment of this class of disease. This testimony is the only sort of evidence at our disposal, because the vital statistics of these towns are practically available only to their health officers and civic authorities, and are not tabulated in any official publication. From these statistics—from a comparison of the number of deaths registered, before compulsory notification was enacted, as "uncertified" (*i.e.*, having taken place without the attendance of a qualified practitioner) with those which took place under similar circumstances afterwards—it would have been easy for the advocates of compulsory notification by the physician to prove that our anticipations as to the exclusion of the physician are unwarranted. They have been repeatedly challenged to this test by ourselves and others, but have kept silence and declined our appeal to facts, and it may therefore be assumed that the figures, if available for public examination, would prove our case. In their absence, however, we are obliged to depend on such

testimony of competent medical authorities as we have been able to collect.

The most complete series of proofs on this point is to be found in a *brochure*, published by Dr. Robert Hamilton, Senior Surgeon of the Liverpool Southern Hospital, and a member of the Town Council. This statement is compiled from replies which the Health Committee of the Town Council had received from the civic authorities of twenty-six towns, and also from the more reliable report of a deputation which had been appointed to investigate the subject, in person, in eight towns in which the compulsory notification system was in force. It would seem that, notwithstanding a special official request made to the medical officer of health of each town that "medical practitioners representing both sides on the notification question" might be invited to meet the deputation, the testimony of the medical profession was deliberately cushioned by the civic authorities, and the deputation was obliged to insist on hearing some such evidence, or they would have returned home with an *ex parte* report dictated by the medical officer of health and town clerk of each such town. We recapitulate, as briefly as possible, the result of these inquiries in reference to concealment, as given by Dr. Hamilton:—

BOLTON.—That concealment of disease occurs was unwillingly admitted by the medical officer of health. This fact is, from its nature, a very difficult one to ascertain. The people who have concealed a disease are not likely to acknowledge it, not even to friends, and therefore it is not at all probable that it should ever come to the ear of the sanitary officer, except in those cases which terminate in death. But if there is one piece of information more than another which has been impressed upon me by my visit to the different towns, as an effect of the compulsory notification of disease, it is this of the concealment of the more prevalent diseases, measles, scarlet fever, and fevers generally, by the public. The slighter cases of all these diseases are kept secret by the parents or relatives—are unattended by medical men—are not surrounded by disinfecting precautions, because of the "tell-tale" nature of the latter; and so these slight cases became the "nidus" from which numerous others, more severe ones, sprung.

BLACKBURN.—The medical officer of health did not think concealment occurred. Dr. Cort, on the other hand, had found it, especially among small shopkeepers and beerhouse-keepers, and Dr. Morley amongst people of a higher grade.

WARRINGTON.—The inhabitants evade the provisions of the Act to a large extent. The sanitary authorities were compelled to admit, though they did it most unwillingly, this concealment of infectious diseases.

LEICESTER.—There is a class of practitioners, and that a very large one in Leicester, who just treat the Acts as a dead letter, and send in no notifications; and the medical officer practically admitted all this. He had "winked, and should think it advisable to wink, at non-notification in many cases." In Leicester the concealment of disease was not disputed.

NOTTINGHAM.—The opinion of an eminent medical man, Dr. Bell Taylor, is a very decided one. That the Act, since it has been put in operation, has not had the slightest effect in diminishing the death-rate, but that it has led to concealment of disease by the householder and by the medical attendant—that the latter do not notify, or if they do, it is often weeks after; also that the operation of the Act has not facilitated isolation of infectious diseases, but rather the contrary, because it had led to concealment, to which isolation would be antagonistic.

From Glasgow, Dr. W. T. Gardiner, one of the most distinguished physicians in the Kingdom, writes as follows :—

In Glasgow, if not in Edinburgh, one of the greatest of evils is that in hundreds of cases of epidemic disease among the poor the medical practitioner is not called in at all, or only casually, and at a very late stage of the disease. In the very cases in which it is most urgent to discover such diseases early—the cases in which there is the greatest ignorance or the most deliberate intention to hush up the facts—the mere idea getting abroad that the doctor is bound in law to notify, to become the “servant of the public” (as it is called), as well as the adviser of the sick man, will be sure to lead to his services being dispensed with altogether, or as long as possible. No doubt the machinery works smoothly enough as long as the householder and the doctor together are agreed as to the public duty of notification. The doctor takes the trouble and responsibility, writes and sends on his certificate, and gets his half-crown, and the thing is done. But I have been long enough a sanitary medical officer to know that those are not the cases that most require looking after.

(To be continued.)

Notes on Current Topics.

Proposed Medical Benefit Society.

SOME correspondence has lately appeared in the *British Medical Journal* in reference to the establishment of a benefit society, to be supported by and affiliated to the parent association. Such an effort, at first sight, must command the sympathy of every member of the profession. It is a laudable ambition to provide against sickness. The medical profession is so badly paid that its struggling members are able to save but little from their scanty incomes, so that the contingencies of illness become serious. As a consequence of this inability to save, many medical men have to work when they are in want of rest, and many valuable lives are thus annually lost. Any scheme which would afford provision in time of sickness must be a boon. This is a truism; and we have watched with interest the list of names sent in support of this movement; but considering the number of associates, it may so far be pronounced a failure. This no doubt arises from many explainable causes: as a rule, the men who really require a benefit society are the last to support it; only the truly provident come forward in a scheme of this kind. We have no doubt that a large accession of members may be expected after the Liverpool meeting. Many now hold back waiting to see what are the chances of success of such a society. Many more would like to see it worked out financially, and to know what premium they would have to pay. Up to the present the financial or actuarial aspect of the question has not been considered sufficiently ventilated or laid before the profession in a manner likely to secure adherents. The first step to be taken before the Liverpool meeting should be to consult the leading assurance authorities in England, and obtain replies to a series of questions relating to premium, benefits, &c. Problematical tables could be easily framed, showing advantages in proportion to number of members belonging to proposed society. It is absolutely necessary that a society of this kind should be financially sound;

there should be no leap in the dark, or experiment tried; all difficulties should be well and carefully considered, and every possible provision taken to prevent and detect fraud and imposture. The scheme must be elaborated in its minutest detail. It would be money well spent if, as we suggest, the leading assurance authorities of the day were consulted, and entrusted with the task of drawing up a perfected problematical scheme.

The Health of our Sailors.

A PARLIAMENTARY paper has been issued containing a memorandum by Mr. Gray, of the Board of Trade, relating to merchant ships, sea scurvy, food scales, and antiscorbutics. The conclusions arrived at in this report were as follows :—1. That scurvy has been on the increase in British ships since 1873. 2. That lime-juice, of itself, will not prevent scurvy, and that too much reliance is placed on it, to the neglect of varied food scales. 3. That lime-juice, in connection with fresh or preserved meat and vegetables, may prevent scurvy. 4. That the dietary scale of ships should, therefore, include a fair proportion of fresh and “preserved” meats, as distinguished from “salted” meats. 5. That more fresh vegetables should be carried, notably raw potatoes. No satisfactory reason is given why fresh potatoes cannot be carried on board British ships. The allegation that they will not keep good on board ship is clearly disproved by the fact that they do keep on board United States ships, and will keep for a fair time anywhere else. 6. That it is not at present desirable to insert a statutory scale of diet in the articles of agreement with crews serving on long voyages, though it may possibly be necessary hereafter, unless the ship-owners themselves move in the matter.

Volunteer Medical Organisation.

SURGEON-MAJOR EVATT'S scheme for the creation of a Volunteer Medical Department formed the subject of discussion at a meeting of the Medical Union Society, on Saturday last, when Mr. James Cantlie, F.R.C.S., of Charing Cross Hospital, occupied the chair. Dr. Evatt, in an introductory address, briefly sketched the history of existing modes of dealing with the wounded in war; and very forcibly insisted on the incalculable advantages which would accrue to the country and to humanity if all students of medicine went through a course of drill to fit them for ambulance service, at the same time as they were pursuing the curriculum of the schools. Mr. Cantlie spoke highly in favour of such training, and as a proof of the interest excited among students by the proposal of Dr. Evatt, referred to the successful formation of classes, numbering forty and thirty-three respectively, at his own hospital. A well-sustained discussion followed after the speeches of Dr. Evatt and the Chairman, and was joined in by Messrs. W. S. Richmond (St. Bartholomew's), Chas. H. Wade (London), Paterson (St. Bartholomew's), Treasure (Charing Cross), &c., as a result of which the following resolution was unanimously carried :—“That this meeting heartily approves of the scheme proposed by Surgeon-Major Evatt, and pledges itself, individually and collectively, to do everything in its power to ensure that the movement shall be successful.” Votes of thanks were passed with hearty

good will to Dr. Eratt and Mr. Cantlie at the conclusion of the meeting, which was throughout of a very enthusiastic description.

A Hint to Anti-Vaccinators.

"AN OCTOGENARIAN," writing to our contemporary the *Standard*, makes certain very suggestive reflections on the influence of vaccination on the people whom it protects. After expressing a wish that those who question the utility of vaccination could, without losing the advantages of youth, receive the memories of his own earlier days, he continues:—"I may safely say that for every person I now meet with seamed or pitted face I then met a hundred, many grievously disfigured, and not a few blind. This was bad enough, though even then, thanks to small-pox inoculation and more lately to the vaccine protection, sufferers were at least in a very decided minority; but I have heard my mother say that in her early days marks of small-pox were so prevalent that it was common to distinguish one free from them as a smooth-faced person."

The Health of Hastings.

THE quarterly report of the medical officer of health for Hastings, dealing with the first three months of the present year, shows that an exceedingly low rate of mortality has been prevalent in respect to the zymotic diseases, being only 0.27 per 1,000 of population, and in actual number 3, the deaths recorded under this head being scarlet fever 2, diphtheria 1. The total death-rate from all causes was no higher than 16.51 per 1,000, notwithstanding that an unusually large number of deaths have been registered as occurring from diseases of the respiratory organs, no less than 64 (including phthisis) being referable to that class. Of twenty-four deaths among visitors to the town as many as thirteen were due to lung disease. Such a statement is a natural one to be made in respect to a health resort which is notoriously sought by invalids in all but hopeless stages of illness; and it is eminently satisfactory to find that under such exceptional circumstances even the mortality of the place is 1.65 below the average of the corresponding period for the last seven years.

Dalrymple Home for Inebriates.

AFTER much endeavour and careful consideration, the committee of management of the Dalrymple Home for Inebriates have succeeded in securing a suitable establishment for the reception of patients under the Habitual Drunkards Act of 1879. This house is situated at Rickmansworth, about four miles from Watford, and comprises about twenty rooms, being surrounded by grounds four and a half acres in extent. Towards the expense of purchasing (£3,700) and fitting the house for the uses it is to serve, the committee now appeal for subscriptions, the sum of £5,000 being required to enable the institution to enter on its beneficent work. In aid of the movement a meeting, to be presided over by the Lord Mayor, will be held at the Mansion House on Thursday, May 31st, at three o'clock in the afternoon. With the aim of the promoters of the Dalrymple Home it is impossible not to sympathise; but it is much to be regretted that the mode of

seclusion of inebriates insisted on by the Act, which requires voluntary declaration of habitual drunkenness by the patient himself before a magistrate, militates so seriously against the prospects of its successful working. The attempt that is being made, however, deserves, as we trust it will receive, hearty and general support.

Death of Mr. Druitt.

THE name of Robert Druitt is one of the most familiar of those who have written in behalf of students, the "Surgeon's Vade-Mecum" having, wherever the English language is spoken, a reputation which is probably not inferior to that obtained by the most universally read of medical text-books. The present generation of students, perhaps less than that preceding it, is accustomed to regard the "Vade-Mecum" as the principal guide to surgical knowledge, for at one time it was *par excellence* among smaller manuals, the authority. Much regret will be felt, therefore, that its author has just recently died, aged sixty-nine, having been born at Wimborne, in Dorsetshire, in 1814. The deceased surgeon was a Fellow of both the Royal Colleges of London, having obtained the highest qualification of the College of Surgeons in 1843 by examination. In the preparation of his principal work, the "Surgery," Mr. Druitt received invaluable assistance from his wife, to whose artistic ability he was indebted for the excellent illustrations which contributed so much to the success of the manual as an educational instrument. He leaves a large family, one son being a member of the profession, and in practice at Clapham.

An American Cancer Quack.

ONE of that brilliant genus of quacks who delight to thrive in luxury provided at the expense of dupes whom they propose to cure of cancer "without the use of the knife," has recently passed through the ordeal of trial in America with the usual result—acquittal. This ornament of practice, Dr. Gast, is not without imitators in this country, the populous town of Stockport containing one, who, we are informed, is rapidly growing rich on the proceeds of his labours. The details of Gast's trial, as recorded in the *Philadelphia Medical Times*, are interesting, because they expose the method pursued by these charlatans who "cure cancer." They apply a caustic paste to the suspected region, and pack it away under the edges of the sore which exists—if none exists they make one—and continuing the process they succeed in removing very extensive areas of integuments, which are next bottled for exhibition as trophies of the "doctor's" skill. In the case in which Gast was indicted *seventy-five square inches* of skin were thus sloughed away, the sole cause for operation being a harmless and very limited sore on the breast of a woman seventy-eight years of age. It is a mournful fact that on both sides of the Atlantic Ocean jurymen should be so easily deceived, as in the case referred to by our contemporary, with the result that rogues of the Gast description are permitted to escape the just penalty of their crimes, and to pursue at will careers of wickedness and fraud in which the sacrifice of human life is the principal consequence of success.

A French Society of Otology and Laryngology.

A MEETING has recently been held in Paris for the purpose of founding a society bearing the above name. A committee of seven members was appointed, five resident in Paris, one from the provinces, and one foreigner. The names are those of MM. Baratoux, Cadier, Gellé, Ménière, and Moure, of Paris; Moure, of Bordeaux; and the foreigner is M. Bayer, of Brussels. M. Baratoux has been appointed secretary for this year, and M. Ménière treasurer. The society will have one extraordinary and two ordinary meetings in the year; the former, being more especially devoted to strangers, will be held about Easter. Among the papers which were read at the first assembly we notice one by M. Naquet, of Lille, "On a Case of Slow Hereditary Syphilis, with Loss of the Substance of the Velum Palati, and Median Otitis," which gave rise to a heated discussion on the diagnosis and treatment. M. Moure, of Bordeaux, read a paper "On Dry Laryngitis;" and that of M. Koch was on "An Interesting Observation of some Foreign Body situated on the Level of the Bifurcation of the Trachea." The next meeting will be held about October, and the exact date will be sent to the members by the secretary.

Hysterectomy.

THE *Medical and Surgical Reporter*, April 14th, 1883, p. 414, notices a case of this nature, the details of which were published in the *New York Medical Journal*, January 27th, 1883.

The patient was under the care of Dr. Emmet, of New York. She was suffering from enlargement of the uterus, due to the presence of eight fibroids, chiefly intra-mural. He used Eschsch's tubing prior to amputating, and after removal of the tumour, transfixed the stump with two needles and secured it with Kœberle's serrenœud. The patient was doing well up to the fifth day, the date on which the report was sent for publication. It seems a pity the result was not waited for and made known.

PROFESSOR F. OGSTON has resigned the Chair of Medical Jurisprudence in the University of Aberdeen. The candidates whose names have been mentioned are Dr. Beveridge, Physician and Lecturer on Clinical Medicine, Aberdeen Royal Infirmary; Dr. Angus Fraser, who holds the same position; Dr. Simpson, Medical Officer of Health, and Lecturer on Public Health, Aberdeen; Dr. Frank Ogston, assistant to his father; and Dr. Aubrey Husband, Edinburgh. Drs. Fraser, Simpson, and F. Ogston, jun., are already in the field.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 27, Bombay 30, Paris 29, Geneva 24, Brussels 29, Amsterdam 29, Rotterdam 29, The Hague 28, Copenhagen 23, Stockholm 20, Christiania 18, St. Petersburg 38, Berlin 27, Hamburg 32, Dresden 26, Breslau 34, Munich 33, Vienna 35, Prague 38, Buda-Pesth 37, Rome 33, Turin 27, Venice 21, Lisbon 25, New York 26, Philadelphia 22, Baltimore 19.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their populations, were—Bradford 15; Edinburgh 16; Derby, Bristol 17; Leeds, Portsmouth, Sunderland 19; Salford, Wolverhampton, Norwich, Nottingham 20; Brighton, London, Oldham 21; Newcastle-on-Tyne, Birmingham, Bolton, Plymouth, Halifax 22; Blackburn 23; Birkenhead, Cardiff, Leicester 24; Manchester, Preston 25; Sheffield 26; Huddersfield 29; Liverpool 30; Glasgow, Dublin 31; Hull 32.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

SPECIAL APPEAL FOR ABERDEEN INFIRMARY.—The question of the financial support of hospitals, no less than their prejudicial effect on public morality and the legitimate interests of the profession, when their benefits are indiscriminately administered, are among the serious social questions of the day. Of this there can be no doubt, that, beyond a limit which is being reached in all large communities, the public will refuse to support them in undue numbers or extravagant size. The city of Glasgow is burdened with two large hospitals, the younger of which is being maintained with extreme difficulty; it is unnecessarily large, and its "benefits" are loosely administered, to the great and unjust injury of the profession; and yet, in face of all this, a third hospital, with its pernicious social and professional concomitants is threatened. That there will be a difficulty in maintaining three large hospitals (other questions apart) in the city of Glasgow is plain to everyone. The straitened circumstances of the Western Infirmary of Glasgow are thus easily explained; but it is not quite so easy to understand why Aberdeen should not adequately support one hospital. Yet we find that the Aberdeen Infirmary, in common with so many hospitals and infirmaries throughout the country, is in an embarrassed financial state. There is at present a debt of £3,300 on this institution, and a committee of the managers, recently appointed, have now issued an appeal for contributions to wipe off this debt, and for new or increased annual subscriptions to the amount of £1,835, in order that the income of the hospital may, in future, be sufficient to meet its legitimate outlay. We hope the Aberdeen Infirmary limits its charity to the really deserving, and that it is not guilty, as so many hospitals are, of pauperising the artisan class, engendering improvidence and dissoluteness, and robbing a hard-worked and underpaid profession. It is estimated that a sum of not less than £6,600 will be required every year to meet the absolute needs of the hospital.

ABERDEEN.—RESIGNATION OF PROFESSOR OGSTON.—Professor Francis Ogston has resigned the Chair of Medical Jurisprudence and Medical Logic in the Aberdeen University. Dr. Ogston was appointed to the chair on its foundation in 1857, but he has lectured on Medical Jurisprudence in Marischal College since 1839, so that his services in connection with the Aberdeen Medical School have extended over a period of forty-four years. The appointment to the chair is vested in the University Court.

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 12th inst., the mortality of Edinburgh was 69, and the death-rate 16 per 1,000. Diseases of the chest accounted for 40 deaths and zymotic causes for 10, of

which 1 was due to scarlatina, and 4 to measles—the intimations of those diseases for the week being 32 and 61. No death was recorded from fever or diphtheria. Of the 131 births, 12 were illegitimate.

ANSTRUTHER.—PAROCHIAL BOARD.—At a meeting of the parochial board of Anstruther, held on the 11th inst., Dr. Colin McCallum was appointed Medical Officer and Vaccinator for the parish, in room of Dr. MacArthur, resigned.

THE GLASGOW DEATH-RATE.—For the week ending with Saturday, the 12th inst., the deaths in Glasgow were the same as during the preceding week, viz., 31 per 1,000, as compared with 26, 26, and 32 for the corresponding weeks in 1882, 1881, and 1880.

KIRKCALDY.—DEATH FROM DRINKING NITRIC ACID (AQUAFORTIS).—On Monday, the 14th inst., James Gow, a brassfounder, residing in Glebe Park, Kirkcaldy, died from the effects of swallowing a quantity of aquafortis. It appears that Gow had been in the habit of using the acid for the purpose of cleaning brass, and about seven o'clock on Sunday morning he had gone to a press with the view of getting some table beer, but mistaking a bottle containing the aquafortis for a bottle of beer, he swallowed a portion of the contents of the former. He shortly afterwards began to take water in large draughts, and on being asked by his wife the reason of this strange conduct, he replied that he had drunk something from a bottle. Mrs. Gow immediately suspected that he had partaken of the dangerous acid, and despatched a messenger for Dr. Dewar, who on arriving applied the stomach-pump (!!), but without giving any apparent relief. Gow lingered on in great agony till ten o'clock in the morning, when he expired. Deceased, who was 42 years of age, leaves a widow and children.

A SHOCKING PRACTICAL JOKE.—Sheriff Lees, Glasgow, on Friday issued decision in an action raised at the instance of Andrew Robertson, who sued Margaret Frame, shopkeeper, daughter of Robert Frame, butcher, for £200 as damages for the death of his child, a boy nearly four years old. It seems that on 31st October last the defender, with the intention of perpetrating a practical joke upon several pony boys, purchased a quantity of jalap for the purpose of mixing it with a plum pudding, part of which she then gave to the boys. The boys handed pieces of the pudding to two killers employed by the defender's father, and they in turn gave the pieces to the pursuer's boy and to another child who was with him. Shortly afterwards the pursuer's child was seized with violent vomiting, which continued to the time of his death on 8th November. For the defence, it was pleaded that the defender was only seventeen years of age, and that her father ought to have been called to the action as her curator; also that the death of the child was not the direct consequence of her act. The Sheriff has found that the circumstances do not warrant sufficient ground for decree, and has dismissed the action, but without granting any expenses to the defender. In a note, his lordship says there are two strong objections to the claim made by the pursuer. If the defender is only seventeen years of age, and if she is living with her father, then he ought to have been called as her curator. But even if that were done, Sheriff Lees doubts the ground of liability would be too remote.

SIR ANDREW WALKER has sent twenty-four framed pictures to the Ayr Fever Hospital. This is in addition to his furnishing the children's ward, and giving £500 as a fund for its support.

GLASGOW ROYAL INFIRMARY.—The new medical and

surgical dispensaries in connection with this institution were opened for patients on Thursday, the 17th inst. On the motion of Mr. M'Clure, Mr. M'Ewen (in the unavoidable absence of the Lord Provost) was called to the chair. The Chairman intimated that he had received apologies from the Lord Provost, Sir James Watson, and Mr. Campbell, of Tillichewan. In the course of an interesting address, Mr. M'Ewen stated that, finding the old dispensary premises inadequate, new accommodation had to be provided. He referred to the important work in connection with the Infirmary which was overtaken by the dispensary department. Specialties received attention at the hands of experienced physicians and surgeons. In connection with the department for diseases of the throat, Dr. Eben. Watson had last year treated 586 cases; with that of the ear, Dr. M'Fie treated 1,136; the teeth, Dr. Woodburn, 1,011; and Dr. Stirton attended every Wednesday at 2 p.m., and gave advice on diseases of women, treating 650 cases. Dr. Stirton had also a special ward in the Infirmary, in which he generally had from 12 to 14 patients. 1,952 vaccinations had been performed by Dr. Tannahill during the year. Mr. M'Ewen expressed the indebtedness of the managers to the dispensary staff, not only in their own department, several of whom received no salary, but in carrying on the work of the house during the absence of the visiting staff. On the invitation of the Chairman, Dr. Wallace Anderson referred to the working of the dispensaries, and to the difficulty in discriminating between such as should receive medicine gratuitously and such as should pay for their medicine. Dr. Campbell Black proposed a vote of thanks to the directors for furnishing such handsome apartments for the out-door patients; and Mr. Peter Clouston, in proposing a vote of thanks to Mr. M'Ewen, warmly eulogised the services he had rendered to the institution, dwelling especially on the zeal and ability which characterised his long connection with such "a grand old institution." The various rooms were afterwards formally inspected.

THE GLASGOW FACULTY OF PHYSICIANS AND SURGEONS AND THE NEW MEDICAL BILL.

[COMMUNICATED.]

ON Friday, the 18th inst., a numerously attended and highly representative meeting of the medical profession in the west of Scotland was held in the Faculty Hall, Glasgow. This meeting was convened by the Faculty, and was, with his usual courtesy and dignity, presided over by the President of the Faculty, Dr. Scott Orr. It were vain and unbecoming to deny that the dead-set made against the Glasgow Faculty, based as it is on reiterated assertion, has raised the indignation, not only of its Fellows and Licentiates, but also, as amply shown at this meeting, of gentlemen holding qualifications from other Scotch bodies. The gravamen of the charge against the Faculty, and in consequence of which reformers south of the Tweed desiderate its virtual extinction, is, in the first place, that, through its portals incompetent men are passed into the profession. Many of us in Scotland are in the habit of thinking that incompetent men pass into the profession through all the portals, and notably those of the Universities, and as the result of the most impartial examination, we cannot find evidence which supports this charge in any special manner against the Faculty. But passing from this general statement, taking as the test of efficiency of examination the proportion of rejected candidates at the Faculty, and comparing them with the rejections at other boards, how does the matter stand? In the course of a long and very judicial address by Dr. Heron Watson at this important meeting of the profession, the reputation of the Faculty as a qualifying body was ably vindicated. Dr. Watson pointed out that the arch-traducer

of the ancient Glasgow Corporation was a gentleman connected with an important medical publication in London, who, in obedience to some fanciful scheme which he entertained as to the licensing of medical practitioners, found that the Faculty stood in his way, and that, while admitting that it was "a corporation of great antiquity, and one that had fulfilled important professional functions in the great and important centre of the West of Scotland," had no hesitation in declaring that it should be expunged as a qualifying body. This assailer of the Faculty does not further dilate on the grounds on which his iconoclastic opinion is based. Surely little importance should be attached to the mere *ipse dixit* of any individual, however influential as a journalist, as threatening the existence of an ancient corporation in behalf of which it is justly contended that it has worthily performed its part to the public and to the profession. Dr. Watson in the same address forcibly pointed out that the evidence of Sir James Paget carries deserved weight; but he further indicates the candour with which Sir James admits that his opinion was based on hearsay evidence, and he believed misinformation. To quote Sir James Paget's own words: "I have not heard the same objection (the examination being too high) made to the examination of the same kind in the Scotch corporations. I fully believe from all I have heard—but I am bound to say it is only by report—that they are at too low a standard." Sir James being asked if he would extinguish any of the Scotch corporations in consequence, replied that the evidence was not strong enough for that. The reader may appraise the value of such vague innuendoes as these. How now do the two Scotch corporations specially assailed, viz., the Edinburgh College and the Glasgow Faculty, compare as qualifying bodies with the College of Surgeons of England? The number of candidates rejected by the English College was 37 per cent., compared with 44 per cent. in the Edinburgh College, and the percentage of rejections at the Glasgow Faculty had risen during the last three years from 37 to 50 per cent. This does not look as if the Faculty examinations were less stringent than that of the English College. Further, and as against the vague accusations levelled at the Faculty, we have the evidence of the visitors of the examinations in Scotland, who report that "the point and plan of the examinations of the Faculty of Physicians and Surgeons of Glasgow are essentially good, and are evidently improving on correct lines. The visitors can speak favourably of the practical effect of the anatomy test introduced into the Faculty examination as being in advance of the London and Edinburgh Colleges. The plan of the Faculty examination is also in every way satisfactory." We submit, then, with perfect assurance, that the vague rumours affecting the Glasgow Faculty examination are baseless, and that its rights are equally entitled to consideration with those of the other Scotch corporations, certainly not excluding the Universities.

The *Lancet* points out that important amendments will be introduced into the Government Bill in the House of Commons, and of these the first, and certainly most important, is to give a title to the new licentiates, that of Licentiate of the Medical Council in Medicine, Surgery, and Midwifery. Without any such title, and the right to practise under it, it is really difficult to conceive wherein the great reform would consist. It is further remarked: "As to the title question, the corporations were never more ill-advised than in pressing the Government to deny a title—a registrable title—to the licentiates of the new Board—this even from the point of view of their own interests." But do the corporations really assume this attitude? Why, at the important meeting under consideration, it was moved by Dr. James Morton, a prominent and respected Fellow of the Glasgow Faculty, "That to all the candidates who pass a Medical Board examination there should be granted a registrable title;" and to the signal honour of the Glasgow Faculty, be it said, this resolution was carried without a dissenting voice.

The *Lancet* further accuses the Faculty of selling "its Fellowship even to those who have been refused a mere licence by other corporations." There is here a *suppressio veri*, if not a *suggestio falsi*. The qualifications for the Fellowship of the Faculty of Glasgow and the Edinburgh College are the possession of a recognised surgical or medical qualification, good moral character, and, generally speaking, personal acceptability to at least two-thirds of the Fellows, a "clubbable man." Properly speaking, the Fellowship in

Scotland is *not* a professional, it is a social qualification, and it is *never* conferred on any one without a recognised medical or surgical qualification. But really in the matter of conferring questionable distinctions, the friends of the Universities as against the Corporations would do well to maintain a discreet silence, when we consider the novel departure conceived by the University of Glasgow of creating Professors by purchase!

The Glasgow Faculty is further informed by the *Lancet* that "its influence in favour of free teaching will be all the greater and purer if relieved of examining duties." This is exactly the argument which medical reformers in Scotland apply to the Universities, between which and the Corporations there is, however, this important difference, that there is practically no limit to the number of teachers in a given branch which the Corporations will recognise, while the University, by means of its qualifying power, provides a virtual monopoly for one. That to be acceptable as a piece of legislation to the profession and the enlightened section of the public the Bill will require considerable amendments in the Commons we firmly believe. The interests and the rights of the great bulk of the profession cannot be longer ignored; the blighting influences of University monopoly must determine, and as the organs of the great bulk of the profession, the claims of the Corporations of Scotland must be considered, and must be respected.

Correspondence.

THE L.R.C.P. ED.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—For some time past I have received a journal called the *Midland Medical Miscellany*. This production is issued by a firm of druggists, and is sent out with their price list. A large portion of this latest addition to medical journalism is taken up with advertisements of the special nostrums sold by the firm. In their last number they have had the good taste to insert a paragraph in which some remarks of not a very professional character are made about my letter on the conduct of the R.C.P. Ed. I trust that it is unnecessary for me to do more than call attention to the grossness of the remarks made, and to say that I do not feel called on to enter into a discussion on the subject in a druggist's circular, which is not to my mind the place for medical men to ventilate their opinion in.

Yours truly,

May 18th, 1883.

L.R.C.P. ED.

UNQUALIFIED PRACTICE IN FRANCE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Pending the coming of the Act, the whole Act, and nothing but the Act which our Legislature is about to be delivered of now, it may be interesting to see how our neighbours manage those things. In your namesake *La Presse* of date I read as follows:—

"The only noise at present in the Commune of Chantilly is about the extraordinary death of R—, formerly an agent of police. He suffered from a skin disease, and went to have a consultation with *un rebouteur* of the neighbourhood, who prescribed for him a certain ointment. R— returned home, rubbed himself with the ointment, and died. The question is, Was the death caused by the ointment, or was it a simple coincidence? As it is impossible to tell which at present, the rebouteur has been handed over to the care of the police, and the dead body has been taken to the Morgue to undergo *l'autopsie legal*."

In review of the affair de Monasterio, where *la pauvre Fidelia* was engaged in a madhouse upon such medical certificates as a major in the army gave (a *soi-disant* doctor), it appears to me that men and manners medical are in France as with us, in a hazy state.

I am, &c.,

Houghton-le-Spring, Durham,
5th May, 1883.

J. O'FLANAGAN.

THE TENURE OF OFFICE OF WORKHOUSE SURGEONS.

THE reply of Sir Charles Dilke to the Birmingham deputation of guardians who were modest enough to ask for the power of capricious dismissal of their medical officers, to which we referred last week, has given rise to much anxiety amongst workhouse officers both in England and Ireland. But it turns out that the President of the English Local Government Board gave very little satisfaction to the deputationists, though he made use of language so ambiguous as to give rise to great apprehension. The account of the interview given by the *Local Government Chronicle* of the 5th of May, which journal is said to be inspired by the Department, says:—

We are in a position to state authoritatively that there is not, and has not been, any intention on the part of the Local Government Board to confer on Guardians uncontrolled powers of dismissal of officers. The Order of the 12th February, 1879, empowers boards of guardians to dismiss certain officers provided that the consent of the Local Government Board is first obtained, and in connection with the proposed new Consolidated Order, the question has been considered whether the Order of the 12th February, 1879, should be made applicable to other officers. It has hitherto been the invariable practice of the Local Government Board when they issued an Order affecting the tenure of office of officers to provide that the Order shall only apply to officers appointed after the date of the Order, and whatever change may be made with respect to tenure of officer by the proposed new Consolidated Order there is not the least probability that its provisions on the subject referred to will affect existing officers.

The last sentence of this paragraph is not satisfactory, for it implies that this injustice may be done to future officers, though those at present in harness are to be exempted from it, and this interpretation is confirmed by the following letter, addressed to the Chairman of the Parliamentary Bills Committee of the British Medical Association:—

Local Government Board, Whitehall, S. W.,
May 7th, 1883.

SIR,—I am directed by the Local Government Board to acknowledge the receipt of your letter of the 1st instant, and to inform you that the statement in the London press to which you refer is incorrect. It is not the intention of the Board to confer on boards of guardians uncontrollable powers of dismissal of officers. Any change which may be made by the proposed Consolidated Order with respect to tenure of office will only apply to officers appointed after the date when the Order comes into operation.—I am, Sir, your obedient servant, S. B. PROVIS, Assistant Secretary.

Any move in the direction of subjecting workhouse officers to dismissal by the guardians would be in direct defiance of the recommendations of two Select Committees.

The correspondence of the Irish Medical Association with the Irish Local Government Board on this subject has been closed by a letter in which the Board refuses to submit the legality of their recent order to the law officers of the Crown, with the view of confirming or refuting the opinion given by Mr. Purcell, Q.C., that this order was *ultra vires* and invalid. Since the letter of the Board was received, the question has been again considered by Mr. Purcell, with special reference to the view of the law put forward by the Board. Thereupon the learned counsel has given his final opinion as follows:—

I have read over the 3rd section referred to in the letter, and admit that on the terms of that section an argument may be founded in favour of the view put forward by the Board, but comparing it with the provisions of the 33rd

section, I am still of opinion that the Board has no power to delegate to the guardians the right of dismissing a paid officer.

T. A. PURCELL.

It remains for the Irish Medical Association to take all possible steps to set aside this order, which, it is advised, is totally illegal, and which, it is of opinion, is altogether unwise and unjust.

No doubt the Association will bring the matter before the higher authorities, and even before Parliament; but it will, we are sure, be ready to go further, and test the question by an application to the Queen's Bench whenever a case of dismissal of an officer by the guardians under the authority of this order arises. Therefore we invite any officer who is thus illegally deprived of his office to communicate with us, and we will undertake to bring the case under the notice of the Association in proper form, and aid in resisting this audacious attempt of the Irish Local Government Board to repeal the Act of Parliament by their own authority.

THE LATE DR. STEELE'S SUCCESSOR.

DR. ROBERT LYNN HEARD, who has been appointed by the Irish Branch Council to succeed the late Dr. Steele, as Medical Registrar for Ireland, received his Membership of the London College of Surgeons in 1855, and became a Fellow of the Dublin College of Surgeons in 1877. He is also an M.D. of the Queen's University, in 1880. He served as Assistant-Surgeon in the 67th Regiment at the taking of the Taku forts and Peking, and was formerly Resident Surgeon of the Belfast Union Hospital.

Obituary.

DR. WILLIAM EDWARD STEELE.

DR. STEELE, well known as the Director of the Science and Art Department for Ireland, and Registrar of the Irish Branch Medical Council, died on the 5th inst., after an hemiplegic attack, with which he was stricken some months ago. He was an Arts Graduate of 1836, and Doctor of Medicine of 1856, of the University of Dublin, and a Fellow, and for many years Registrar, of the Irish College of Physicians. During the earlier part of his career he lectured on *Materia Medica* in the Dublin School of Medicine, and for several years was one of Sir Patrick Duane's Hospital. His special studies were in the domain of Botany, at which he laboured with much success, publishing in 1852 a "Handbook of the Botany of the British Isles," which went through two editions, and which he was engaged in revising for a further issue up to a short period before his death. He was a skilled microscopist, and for many years a member of the Dublin Microscopic Club, and his active mind was constantly employed upon questions of art and science. In this way he became a skilled musician, not only as a performer, but as a composer of many pieces of church music, the construction of which marked him as thoroughly acquainted with the principles of harmony.

To the *University Magazine* he contributed, some years ago, the correspondence of Colonel Dennie, an officer who took a distinguished part in the first Afghan campaign. Of late years Dr. Steele's time was fully occupied by his duties as Secretary of the Royal Dublin Society, in which capacity he acted for more than a quarter of a century, and as Registrar of the Branch Council, which appointment he held for twenty-three years. To his energies, talent, and industry was, in great measure, due the advancement of the Dublin Society, and, through it, of the material progress of scientific agriculture in Ireland. Upon his retirement from the Secretaryship, which he resigned in 1878 to take up the appointment of Director of the Science and Art Department, his friends

testified their esteem for him by presenting him with an address and a handsome service of plate.

His death is felt to be a serious loss to the institutions which he had so long and so ably served, and his personal qualities were testified to by the sorrow with which the news of his death was received by all who knew him.

DR. FRIEDRICH FIEBER.

AN accomplished and much-regretted foreign *confrère*, Dr. Friedrich Fieber, who always had for English doctors a specially warm welcome to his *clinique* for electro-therapeutics and inhalations at the General Hospital, Vienna, has lately passed away, at the early age of 48, after many months of acute suffering consequent on a fracture of the thigh, the result of a tramway accident. Dr. Fieber was a native of Prague, a physician in large practice, and the author of several well-known works on diseases of the throat, inhalation, and electro-therapeutics. He devoted much time to the study of electrolysis as applied to the treatment of tumours, and he was indefatigable in his hospital wards in carrying out the electrical treatment of nervous diseases. With him the name of Fieber does not become extinct in medical circles. His brother, Dr. Carl Fieber, a very able Viennese surgeon, still survives; and it is to be hoped that he will not be often mistaken for his late lamented brother and reported dead, as he was recently to a friend of ours at Vienna.

Literature.

A TREATISE ON FOREIGN BODIES. (α)

THERE is a certain class of book in medical as well as general literature which, though it may not possess sufficient to interest the general reader, still must rank high as a book of reference, and as such ought to hold a place in every library. Such, now, is the work before us. No surgeon has hitherto thought of collecting in one book all the material which is scattered through the annals of science concerning foreign bodies. Dr. Poulet has not only collected, but classified them into two volumes, which, if we mistake not, will find a place, not only in the large libraries, but in the studies of the busy practitioner.

The first portion of Vol. I. is given up to a review of foreign bodies in general; the second part commences with foreign bodies in the intestines.

We will content ourselves by quoting one of the numerous interesting cases collected in this portion of the work:—"Napoleon gives the history of a case: 'When I commanded at the siege of Mentone, shortly before the surrender of this fortress, a German was arrested while endeavouring to enter the city. The soldiers, who suspected him of being a spy, searched him without success; they then threatened him in their own language, which he did not understand. Finally, a Frenchman was called who spoke German slightly, and who threatened him, in bad German, with instant death if he did not at once disclose all he knew. He accompanied this threat with furious gestures, drew his sword, placed the point of it upon his belly, and said that he was going to slit him open. The poor German, frightened, and not understanding the jargon of the French soldier, imagined, when he saw him threatening his belly, that his secret was disclosed, and cried out that it was unnecessary to slit him open, and that if he waited a few hours it could be obtained in the natural manner. This gave rise to fresh questions. He stated that he was the bearer of despatches for Wurmser, and that he had swallowed them as soon as he found himself in danger of being captured. He was carried to my head-quarters, whither several physicians were summoned. It was proposed to administer a purgative; but they stated it was best to await the operation of nature. He was then confined to a room under the surveillance of two staff officers, one of whom was constantly near him. After several hours the expected object was found. It was enclosed in wax, and was as large as a nut. When opened it was found to be a despatch written in the hand of the Emperor Francis, and which requested him not to be dis-

couraged, and to hold out a few days longer, when he would aid him with a strong column."

Next follows foreign bodies of the pharynx and œsophagus. Here, too, we find collected some interesting cases. The following example, taken from the *Lancet* of 1873, is interesting:—"MacLauren reports that a young man, while fishing in the low waters of a brook, wished to kill a fish which he had caught with his teeth. This fish, which measured three inches in length, and a half-inch in width (English measure), made a sudden movement and fell into his fauces. This was immediately followed by suffocation, nausea, efforts at vomiting, expectoration of blood and mucus, emphysema of the face, neck and chest. The fish could easily be felt, but could not be extracted on account of its sharp fins, which were embedded in the tissues. Attempts to push it down proved fruitless, and the patient was then made to swallow a great deal of vinegar and water. The fins became detached, and in less than 24 hours the fish was pushed down. At this time the emphysema extended to the scrotum, muco-purulent expectoration developed, and on the third day complete aphonia. All these symptoms gradually diminished without any further interference, and the patient had recovered eight days later."

Foreign bodies in the stomach and intestines next occupy the attention, and here may be found many interesting cases. One will suffice:—"A shepherd dwelt with his children in a cabin, which was infested every night with a large number of mice. One of the children slept with his mouth open, and a mouse suddenly entered it. The child, by an involuntary movement of deglutition, pushed the mouse into the stomach—pain, vomiting of blood. At the end of forty-eight hours the child passed a large mouse by the bowels; it looked as if crushed lengthwise, and its skin was denuded here and there. The child was ill for a long time, but recovered."

Vol. II. commences with foreign bodies in the air passages, then those in the genito-urinary organ; and the last portion those which find their way into other portions of the body.

The most useful portion of the work is that which treats of the extraction of foreign bodies, and this alone would be sufficient to recommend its perusal.

The whole book bears the stamp of very considerable labour and perseverance, but if we might suggest an improvement it would be, that in the next edition the scissors should be freely used, and the whole condensed into half its present size.

PASS LISTS.

Royal College of Physicians of London.—The following gentlemen were admitted Fellows on May 17th:—

Allbutt, Thomas Clifford, M.D. Camb., Leeds.
Cook, Henry, M.D. St. And., Shaldon, Teignmouth.
Dreschfeld, Julius, M.D. Warzburg, Manchester.
Elliott, George Frederick, M.D. Dub., Hull.
Gover, Robert Mundy, M.D. St. And., Home Office, S.W.
Murrell, William, M.D. Brussels, 38 Weymouth Street, W.
Fawyer, James, M.D. Lond., Birmingham.
Warner, Francis, M.D. Lond., 24 Harley Street, W.

The following gentleman was admitted Licentiate:—
Johnson, George Arthur, Guy's Hospital, S.E.

Royal College of Surgeons of England.—The following candidates, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on Monday, May 14th:—

Camps, Samuel, L.R.C.P. Ed.	Mitchell, Henry, I.S.A.
Dodd, Anthony, L.S.A.	Morris, Albert, L.R.C.P. Ed.
Dowsing, H. Leopold, L.S.A.	Nicholson, J. William, L.S.A.
Doyle, E. A. Gaynes	Peskett, A. Freeman, L.S.A.
Etches, W. Robert	Phillson, S. Co well, L.R.C.P. Ed.
Gravelly, Frank, L.S.A.	Tatham, Edward, L.R.C.P. Ed.
Hathaway, H. George, L.S.A.	Vann, A. Mason, L.S.A.
Hitchcock, A. John, L.S.A.	Walter, W. Ernest, L.S.A.
Kay, Walter Smith, M.B. Ed.	Whitfield, D. W., L.R.C.C.P.
Wilson, James, M.D. Dub.	

The following were admitted on Tuesday, May 15th:—

Edgelow, Percy	Rowe, Arthur Walton
Gutteridge, Matthew Wilkins	Shorthouse, W. S. Neville, F.A.
Maling, William Haygarth	Smallpiece, William Deane
Martin, Albert	Stewart, Edward
Roberts, Edward, L.S.A.	Walton, Francis Melrose
Rogers, Frederick Arthur	Wilson, James

(α) "A Treatise on Foreign Bodies." By Alfred Poulet, M.D., Adjutant Surgeon-Major; Inspector of the School for Military Medicine at Val-de-Grace.

The following were admitted on Wednesday, May 16th :—

Carter, Eustace George
Coakey, Edward Percival
Croft, Edward Octavius
Fakken, E. B. Drummond
Forrest, John Rochell, L.S.A.
Harrison, Edward

Oliver, Vere Langford
Polson, James Ronald
Pulling, Herbert John
Spong, John Fuller
Stephen, Samuel, L.S.A.
Stokes, Francis Alexander.

The following were admitted on Thursday, May 17th :—

Brewster, William, L.S.A.
Cock, Frederick W., L.S.A.
Glover, John P., L.R.C.P.Lond.
Griffiths, A. P., Henry
Hicks, George B.

Kershaw, James E.
Levi, Reuben, M.D. McGill
Mickle, Herbert, M.B. Toronto
Rouse, Rolla E., L.S.A.
Verity, H. W. Steele, L.S.A.

The following were admitted on Friday, May 18th :—

Batt, E. B. Drury, L.S.A.
Bindley, Victor N., L.S.A.
Buckley, Thomas W., L.S.A.
Collins, Edward T., L.S.A.
Halpin, R. F. Bestall

Hart, Herbert Wheatley, L.S.A.
Jones, Robert, M.B. Lond.
Mason, Arthur H., L.R.C.P.Lond
Style, Mark, L.R.C.P.Lond.
Thornton, H. J., L.R.C.P.Lond.

Notices to Correspondents.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

MOORE FUND.

THE Rev. F. R. Miller begs to acknowledge with thanks the following additional contributions :—

T. Smith, Esq., £3 5s.; J. P. B., 10s.; Beta, £2 2s.; Poor Apothecary, 5s.; Chas. Young, Esq., 10s.; Dr. Holden, 5s.; T. C. Beatty, Esq., 10s.; Dr. Coombes, 10s.; H. Harvey, Esq., 10s.; J. Watts, Esq., £1; Anon. (Sunderland), 10s.

DR. GODSON.—The paper has been duly received, and shall have insertion at the earliest possible date.

MR. NIXON.—Death certificates are not usually charged for by medical men, nor can any payment be exacted for them, the attendant being compelled, under penalty of a money fine, to certify the cause of death in cases under his charge. When, from circumstances, he feels unable to do this conscientiously, he must specify the reasons for his objection.

MR. SIDNEY DAVIES (Cairo).—We shall be glad to receive the Reports.

DR. M. K. G.—Not possible in the present number. On a more favourable occasion we shall be pleased to refer to the subject.

SIR WM. MACCOEMAC.—Received as we were going to press. Too late for reference this week.

MR. NORMAN PORRITT (Huddersfield).—Evidently an oversight. Will make inquiries.

DR. HOGGAN will please receive our thanks.

MR. CARRAN.—Your surmise is not at all correct. The precedent does not hold by any means, as you will at once perceive on reading through the list of presidents during recent years. The distinction to which you refer has been conferred for eminent services to humanity, and for no mere official labours. On this account it possesses a vastly greater significance.

"THE DOCTOR."—Your letter is crowded out of present issue; it shall appear in our next.

L. N. (Liberty St.).—The matter is at present under the consideration of the Poor-law Board. No such Act as that referred to has been passed during present session.

THE APPOINTMENT OF HOSPITAL BEDS TO CONSULTANTS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been drawn to a paragraph in your issue of April 25th, p. 367, stating that the Senior Physician of the Liverpool Infirmary for Children, on his retirement to the consultant staff, is to have six beds apportioned him, and that "for the first time in hospital management a consultant is to have beds," &c. Some months ago the committee of the Leeds Infirmary were announced in the weekly medical journals to have arrived at a similar resolution; and doubtless a similar arrangement prevails in other hospitals. The desideratum consists in affording the eager juniors opportunities for study as medical officers to a hospital, and yet not lose the experience of those who have advantaged and made good use of their appointments as medical officers to our hospitals. The arrangement suggested will help much, and is to be favoured.

Yours truly,

P. M. BRADWOOD.

Birkenhead, May 18th, 1883.

FEES FOR SANITARY PROSECUTIONS.

J. W. asks.—Can I recover two separate fees for £1 1s. each from the Board of Guardians for my evidence in two cases of prosecution under the Sanitary Act? The presiding magistrate made an order in each case for payment.

Nevertheless, the board of guardians has refused to pay me, as they imagine, because I am paid a salary as sanitary officer. I should also go out of my district as a witness, no matter what the inconvenience may be. I may state I was not summoned as a witness, but went when asked by the relieving officer.

[See 259 of Public Health Act ("Irish Medical Directory," page 666) provides that every officer of a sanitary authority shall attend and assist in any prosecution instituted by such authority on receipt of an order from such authority so to attend: provided always, that if any officer of the sanitary authority shall so attend and assist, he shall be entitled to remuneration from the sanitary authority at

such rate as the L. G. B. shall approve, unless it shall have been agreed that the duty of affording such attendance and assistance shall be included in his salary, or that his whole time should be occupied in the discharge of the duties of his office; and such payment shall be deemed to be expenses incurred by the sanitary authority under this Act, and may be recovered as part of the costs of the prosecution. The order from the board of guardians must proceed from an authorized officer, as the R. O., but may be verbal or written. If the medical officer on his appointment agrees to include sanitary prosecutions within his duties, he can recover nothing, otherwise he must be paid.—Ed.]

MEETINGS OF THE SOCIETIES.

FRIDAY, MAY 25TH.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. R. J. Lee, On a Case of Nystagmus Infantilis.—Mr. A. E. Barker: 1. On a Case of Goutre producing great difficulty of Breathing on Exertion; Excision; Recovery and complete Bellef. 2. On a Case of Sebaceous or Dermoid Cyst of the Tongue; Removal by Submental Incision; Cure. Dr. Habershon, On a Case of Ulceration of the Stomach at the Pylorus, in which Food relieved Pain.—The following cases will be exhibited:—Mr. J. R. Lunn: 1. Myxodema, Male and Female. 2. Peculiar Deformity of Wrists, probably of rheumatic origin. Dr. D. Drewitt: Myxodema. Dr. F. Taylor: Infantile Hemiplegia, with unusual Reflex Phenomena.

TUESDAY, MAY 29TH.

ROYAL INSTITUTION.—At 3 p.m., Prof. McKendrick, Physiological Discovery.

Vacancies.

Armagh Union, Blackwatertown Dispensary.—Medical Officer. Salary, £120, and £20 as Medical Officer of Health. Election, May 28.
Bristol General Hospital.—Physician's Assistant. Salary, £50, with board. Applications to the Secretary before May 28.
Doncaster Infirmary.—House Surgeon. Salary, £100, with board. Applications to the Hon. Sec. before June 3.
Dorset County Asylum.—Assistant Medical Officer. Salary, £140, with board, &c. Applications to the Chairman of Visitors at the Asylum, Dorchester, before May 28.
Denbighshire Infirmary, Denbigh.—House Surgeon. Salary to commence at £85, with board and residence. Must be conversant with the Welsh language. Applications to be sent to the Secretary before May 26th.
Hospital for Sick Children, London.—Junior Resident Medical Officer. Salary, £50, with board, &c. Applications to the Secretary, Great Ormond Street, by May 30.
Isle of Wight Rural Sanitary Authority.—Medical Officer of Health. Salary, £300. Applications to the Town Clerk, Newport, before June 6.

Appointments.

BROWN, F. G., M.R.C.S., L.S.A.Lond., Honorary Medical Officer to the Hospital Saturday Seaside Convalescent Home for Working Men.
DAVIES, E., M.D. St. And., M.R.C.S., L.S.A.Lond., Medical Officer of Health for the Northern Division of the Wrexham Rural Sanitary District.
EDWARDS, H. J., L.R.C.P.Ed., L.R.C.S.Ed., a House Surgeon to the Royal Infirmary, Edinburgh.
GRANT, J. D., M.A., M.D., Assistant Surgeon to the Central London Throat and Ear Hospital.
HARPEL, J. W., M.B.C.S., L.S.A.Lond., Medical Officer of Health for the Stowmarket Urban Sanitary District.
HICKS, J. B., M.D., F.R.S., Consulting Obstetric Physician to Guy's Hospital.
JAKINS, F., M.R.C.S., L.S.A.Lond., Registrar and Pathologist to the Central London Throat and Ear Hospital.
LAIMBEER, F. J., L.R.C.P.L., M.R.C.S., Resident Medical Officer to the Liverpool Royal Infirmary.
MACINTOSH, G. D., L.R.Q.C.P.I., Medical Officer for the Hallaton District of the Uppingham Union.
SUTTON, Mr. F., re-appointed Public Analyst for the County of Norfolk.
WRIGHT, A., M.R.C.S., L.S.A.Lond., Medical Officer for the First District of the Romford Union.

Births.

BLAKE.—May 16th, at Ravensdale, Dundalk, the wife of Dr. Richard Marlay Blake, of a son.

Deaths.

ALLATT.—May 14th, at 12 Pencaster Road, Dover, Christopher John Robert Allatt, M.D. Trinity College, Cambridge, F.R.C.P., aged 88.
ARNISON.—May 10th, at Allendale Town, Northumberland, William Campbell Arnison, surgeon (retired), aged 85.
DRUITT.—May 15th, at Strathmore Gardens, Kensington, Robert Druiitt, M.D., F.R.C.P., F.R.C.S., aged 63.
GILL.—May 14th, at Canterbury, John Beadnell Gill, M.D., formerly of Dover.
ROBINSON.—May 10th, Richard Rodd Robinson, M.R.C.S. (son of the late Ruby Vane Robinson, Lieutenant of the—now Royal—Marines, who was mortally wounded in Nelson's unsuccessful attack upon Teneriffe in 1797), aged 91.
WHATMOUGH.—Recently, at Cinderford, Charles Whatmough, M.D. Ed. M.E.C.S., aged 60.

HEDGES & BUTLER

SHIPPING CELLARS—JEREZ (SPAIN).
 LONDON Do.—155 REGENT STREET.
 BRIGHTON Do.—30 KING'S ROAD.
CHAMPAGNE,
CUVEE EXCEPTIONELLE, BRUT.

Of this choice and very old Champagne Messrs. HEDGES & BUTLER have remaining about 900 dozen, which they can strongly recommend to Connoisseurs and Invalids, on account of its perfect freedom from added Spirit and Saccharine. Price, 96s. per dozen; 50s. per dozen Half Bottles. Particulars and Priced Lists of all Wines and Spirits on application.

Grand Supply TO H. B. H. the Prince of Wales.
 (Established 1835.)

NO. 11 LITTLE STANHOPE STREET, MAYFAIR W. (TOP OF DOWN STREET, PICCADILLY).
 Beg respectfully to call the attention of the Trade to their

LIQ. ERGOTÆ PURIF. (HEWLETT'S).

This preparation, which has now been well tried by many hundreds of medical men, was introduced by us about two years since, to supply a want that was felt, and thus obtain a reliable and active preparation of Ergot. Perhaps there is no drug of which we hear such contradictory results as to its action and use. Several things may fully account for this: the inertia of the drug employed, the dose administered, and the manner and the time of giving it. Various preparations, such as the Liquid Extract of the *British Pharmacopœia*, many of the ammoniated liquid extracts, the stale powder, and the tincture, are inert or nearly so. Heat is said to be destructive in preparing the drug, though this may be doubted by many old practitioners who have, from time immemorial, been in the habit of making at the bedside an infusion from the powder or the beans. Being satisfied that there was real cause for the numerous complaints as to the uncertainty of the various preparations used by medical practitioners, we have succeeded, after many experiments, in obtaining a pure liquid extract, which, we are glad to say, has given immense satisfaction to the accoucheur, and in general practice, in the various diseases that the drug is indicated, and which are considered *seriatim*.

Liq. Ergotæ Purif. (Hewlett's) can be administered with effect:—

1st.—In tedious labours, where the pains are infrequent and of no force, and where the os is dilated, and when the uterus is becoming exhausted, one or two drachms of the Liq. Ergotæ Purif. (Hewlett) given in a little water excites powerful and continued contractions of the uterus.

2nd.—In post-partum hæmorrhage, Liq. Ergotæ Purif. (Hewlett) administered in half to one drachm doses is very conspicuous in its action in arresting the bleeding, by producing firm contraction of the uterus, and by its influence on the blood-vessels in diminishing their calibre. When the patient is reduced almost to a hopeless state, the dose may be increased and repeated every hour or two if necessary.

3rd.—It has been given with success on the Continent, in that troublesome class of cases following enlargement of the prostate gland, as it causes diminution of its substance by its peculiar action on involuntary muscular fibre, and it has been lately prescribed with marked benefit in cases of diabetes insipidus, in diminishing the amount of urine.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., 90-oz. Bottles. Physicians will oblige, when ordering this preparation, to write "Liq. Ergo Purif. (Hewlett's)"

Specially Prepared by C. J. HEWLETT & SON,

Operative Chemists, 40, 41, and 42, Charlotte Street, LONDON, E.C. Price 10s. 6d. per lb.

WRIGHT'S

See Testimonials of entire Medical Press and from leading Dermatologists.

THE PRACTITIONER, of September, 1861, reports a lecture entitled "Recent Advances in the Therapeutics of Diseases of the Skin," by W. A. Jamieson, Esq., M.D., &c. The following is an abstract therefrom:—"Itching, which owes its origin to too slow a current of blood, of which the most typical example is that seen in Eczema connected with varicose veins of the leg—but to the same category also many examples of Pruritus Scroti, Labiorum and Ani may be referred—is best relieved by careful flannel bandaging, well applied suspensory bandages, and laxative salts or mineral waters, which unload the rectal veins by freeing the portal circulation, combined locally with weak tarry lotions, one of the best of which is Wright's Liquor Carbonis Detergens, a well-made solution of Coal Tar, suitably diluted."

From THE LANCET, Dec. 22nd, 1866: "In our hands it has been a most effective agent in skin diseases, especially of the chronic eczematous class; and one case of psoriasis, which had resisted all other kinds of treatment, speedily got well under the application of the Liquor Carbonis Detergens. We esteem it a very valuable addition to our list of skin remedies."

From the MEDICAL TIMES AND GAZETTE, January 19th, 1867:—"We have more than once called attention to the value of this remedy in chronic eczema."

From the BRITISH MEDICAL JOURNAL, September 22nd, 1871:—"We have tested it and can affirm its value as a detergent agent. We consider the Liquor is an article of great utility." Kept in stock and sold by all Druggists (Wholesale and Retail) throughout the United Kingdom and Colonies.

ON

HYSTERICAL CONTRACTION OF TRAUMATIC ORIGIN.

By J. M. CHARCOT, M.D.,

Professor to the Faculty of Medicine, Paris; Physician to the Salpêtrière Hospital; Fellow of the Clinical Society of London, &c.

(Concluded from page 440.)

LECTURE III.—TWO CASES OF HYSTERICAL CONTRACTION OF TRAUMATIC ORIGIN.—(Concluded.)

GENTLEMEN,—Our patient is a man of 34 years of age, a blacksmith, the father of four children, moderately robust, and without any attribute of feminism. I would observe that in his history we have been able to trace no hereditary or personal antecedent of a nervous order, nor any moral emotion which might be held accountable for his disease, with the exception of that arising from a burn. On the 26th of June last a bar of iron at white heat touched his forearm and his left hand. The wound although quite superficial did not heal for six weeks, and at the present moment there remains a reddish-violet patch of from 3 to 4 centimetres by 10 to 12, occupying the inferior portion of the forearm and the back of the hand. The accident it would appear did not occasion an exaggerated amount of emotion. Furthermore, the contraction did not follow immediately after the receipt of the burn; strange to say it gradually developed. Some days after the accident he says he felt his arm heavy and a difficulty of moving his fingers without feeling as if they were benumbed; but for the contraction, without the intervention of any new cause, it did not occur until after seven weeks. On the 15th of August pains were felt in the forearm, patient did not sleep, and the following day his hand presented the characteristic attitude arising from interosseus spasm, the thumb being free. The next day flexion of the fingers supervened, and finally the thumb is applied in turn against the other fingers. During these periods flexion of the wrist, and pronation of the forearm take place succes-

sively. Let us examine more particularly this remarkable deformity of the hand, the result of a permanent contraction of certain muscles, a contraction so pronounced that it resists every attempt at reduction, and which during three months remained without intermission, not only during day, but, and on that point I lay stress, during the night. The shoulder and the arm are free; the forearm is in a state of pronation. The hand is flexed in the forearm; the four fingers are so flexed that the nails imprint the palm of the hand. The fingers are violently locked in one another, and the thumb is firmly applied against the external surface of the second phalanx of the index finger.

Here the most simple physiological analysis demonstrates that it is the median nerve which is in abnormal activity, seeing that it supplies the flexors of the wrist together with the superficial and deep flexors. But the ulna nerve is also in action, the adduction of the fingers reveals the action of the *interossei* muscles. We shall add that the extensors are also in action, as in every spasmodic contraction. Observe that attitude of the fist, closed, and very energetically closed, I insist, complicated with a flexion of the hand which is also energetic. There is here you will observe a fixed attitude of the first degree, an attitude difficult voluntarily to maintain for a very short time. This is the place to remind you of an ingenious remark of M. Duchenne. You know that in the hand the flexors and extensors are in a sort of antagonism to one another. If one extend the hand as much as possible and then endeavours to extend the fingers the latter become slightly flexed. The extension of the hand causes shortening of the extensors of the fingers, and consequently renders their action less potent, although that on the contrary the flexors of the extended fingers are also set in action. Conversely, and for a similar reason, if you flex the hand the fingers are easily brought into a position of complete extension. Meanwhile consider the combined action of the flexors of the hand and those of the fingers; there is here a sort of antagonism. Thus to firmly flex the fingers and shut the fist, as in an attitude of menace, the hand is extended, and the action of the extensors favours that of the flexors. If, on the contrary, the fist being strongly shut, you energetically flex the wrist you then observe that the

flexion of the fingers relaxes, and that they have a very marked tendency to extend. You cannot, without great effort, maintain them flexed in that position of the hand. This is a fact of such a nature as to exclude the supposition of simulation. No person would be able for many hours—not to speak of days—no matter what motive, to maintain his hand in the truly pathological condition of our patient. It is absolutely certain, in any case, that no one could so maintain the hand during profound sleep. But in our patient this attitude is maintained during sleep, as M. Debove has repeatedly observed. Furthermore, we purpose to submit our patient to the pneumographic test, and I do not doubt that the result will be the same as in the young girl whose case we have already mentioned. [This test was applied, and with the same results as in the young female patient.]

You, therefore, will concede that here we have to do with a true pathological condition, and not one voluntarily caused by the patient. It remains for me to establish that, as in the case of our female patient, it is a case of genuine hysteria with which we have to deal. I have already observed that this is a modified form of hysteria. The patient has had no attacks; there is neither psychical nor other antecedent to note. But if we refer to the observations made by M. Debove on the 1st of October, and to those made by ourselves a week subsequently, we find—1st. Left hemianalgesia; pinching causes no pain, only the sensation of simple feeling; cold is less appreciated along the whole of the left side of the body. 2nd. There is a marked perversion of taste, hearing, and smelling, on the left side. Proceeding to measure the field of vision, we find that it is circumscribed on both sides, but especially on the left; that for colour, is also limited in proportion, but the concentric circles which represent the field for each colour have preserved their relative reciprocal proportions; there is no transposition; no achromatopsy, and no dischromatopsy. 3rd. There is no trace of any hysterogenic zone. Be that as it may, in the absence of every other condition likely to provoke such symptoms, this contraction of the hand cannot possibly be due to any other cause than hysteria; and it presents, as we have seen, striking analogies with that of the young female whose case we have considered. Such was the state of the patient on the 7th October. Since then the condition has somewhat modified. Magnetism has been applied to the site of the contraction. Sensibility has gradually returned to the superior extremity, to the trunk, to the head, to the arm, but not to the hand or wrist. After an interval of absence from hospital, the patient returned. Galvanism has been reapplied, and the insensibility of the hand disappeared, but provoked a numbness, and the commencement of rigidity in the opposite hand. At present, the contraction alone persists. The hemianæsthesia has completely disappeared. A feeling of painful cramp exists in the contracted part, which sometimes causes trouble during sleep. [In a note by Dr. Charles Féré, it is stated that suffering from extreme pains in the forearm, due in part to the penetration of the nails in the flesh, and partly to the contraction itself, and the patient being urgent for surgical interference, M. Charcot had recourse to stretching of the median nerve, with the result that the pains in the forearm had disappeared, as likewise the contraction, though the fingers could not be completely extended.]

SOME REMARKS ON PUERPERAL ECLAMPSIA. (a)

By J. E. BURTON, L.R.C.P. Lond.,
Obstetric Physician to the Ladies' Charity and Lying-In Hospital,
Liverpool.

(Continued from page 444.)

Now comes the question, How is this degeneration of renal epithelium produced? Braun and the earlier writers attributed the kidney change to venous congestion

from pressure of the gravid uterus on the kidneys. This cannot always be the cause, for not unfrequently, according to Flaischlen, just quoted, the albumen often appears about the middle of pregnancy, when, of course, the uterus is not high enough up to press upon the kidneys. Dr. McDonald, in 1880, says that "all attempts to explain the very frequent occurrence of renal disease on purely mechanical grounds must be allowed to have proved in a great measure failures." Halbertsma, on the other hand, claims to have discovered a ground of explanation, and that a mechanical one. In 1871 he first drew attention to pressure by the gravid uterus on the ureters as the cause of the kidney degeneration. Last year he returned to the subject with convictions strengthened by 11 years' observation and thought. He points out the difficulty of verifying this pressure after death, and shows that only the effects of such compression should be looked for—catarrh and swelling of the ureters, and these have, as he says, been actually observed. This view has been adopted and defended by Lohlein, (a) who has made autopsies in a great many cases. He has found dilatation of one or both ureters in 25 per cent. of the cases of death from puerperal eclampsia, and only in 3 per cent. in cases of death from other diseases. Hiller has also adopted this view, and seen proof of the accuracy of it *post mortem*. Cruveilhier has been pressed into the service of this theory, and his statement that when the lower segment of the uterus is firmly distended, it must press upon the ureters, and thereby occasion dilatation of them, has been made use of in support of it. This view also receives the support of Dr. Matthews Duncan, who, in his recently-published "Lectures on Diseases of Women," p. 81, makes use of the following language: "Recently many observations show that obstruction of the ureters has a good deal more to do with the nervous phenomena of pregnancy, and even with uræmic eclampsia, than we have hitherto supposed." The mechanical theory certainly receives great support from the facts that a great preponderance of the cases of eclampsia occur in primipars, in whom the abdominal walls are comparatively tense and unyielding, and that again a large proportion of these are unmarried girls, who, to keep the appearances of pregnancy in the background as much as possible, voluntarily undergo the tortures of tight lacing, and than press the uterus back upon the ureters, with too often fatal determination and persistency.

Having now considered the important contributory part that uræmia, whether associated with albuminuria or not, plays in the production of puerperal eclampsia, we have to turn to those cases in which no uræmia exists. That there are such cases all are agreed. Luak says that in addition to eclampsia owing its origin to central causes—the central causes being, I take it, uræmia—"there is another class in which the convulsion proceeds from peripheral causes." "Without uræmia peripheral irritation can provoke eclampsia." There must be some common cause producing the convulsion in both classes of cases—those in which there is uræmia and those in which there is none. It seems to me that it would be just as reasonable to put down all infantile convulsions to anæmia as it is to attribute all puerperal convulsions to that cause. Most writers have omitted to mention the common cause that is operative both in the convulsions of childhood and those of the puerperal state. Playfair says: "The key to the liability of the puerperal woman to convulsive attacks is, no doubt, to be found in the peculiar excitable condition of the nervous system in pregnancy, a fact which was clearly pointed out by the late Dr. Tyler Smith and by many other writers." Dr. Barnes has also drawn attention to this peculiar state of "unstable equilibrium," as it might be called. Flaischlen calls it a state of predisposition, which may be taken to mean the same thing. In childhood, then, in pregnancy, and in epileptics permanently, this condition of unstable equilibrium may be

(a) Read before the Liverpool Medical Institution, April 26th, 1883.

(a) *Deut. Med. Zeitung*, 1883, p. 1

said to exist, and this is the one factor that is indispensable, and there is no other that is.

As to the immediate cause of the attacks most writers are agreed. Tenner and Kussmaul are said to have proved that the immediate cause of epilepsy is anæmia—cerebral anæmia.

Dr. C. C. P. Clark says that the condition of the system in epilepsy and puerperal convulsions is essentially the same. (a)

Hughlings Jackson believes that the attacks are due to anæmia of brain from spasm of cerebral arteries.

Nothnagel has proved that a collection of ganglionic cells in the substance of the pons furnishes the motor centre from which the convulsive impetus takes its departure. (Lusk, p. 534.)

McDonald, in his fatal case, found the meninges of the brain intensely congested, but the motor tract equally anæmic. He attributes eclampsia to over-stimulation of the vaso-motor nerves, which in turn produces anæmia of the brain.

Bidder (b) says: "It seems established in our day that the cause which engenders eclamptic convulsions or epilepsy is a sudden arrest of cerebral circulation. The vaso-motor spasm which is developed determines a sort of instantaneous ischæmia."

To summarise, then, I think we may conclude, from the evidence before us—

1. That puerperal eclampsia is a motor neurosis associated with loss of consciousness.
2. That it stands in intimate relationship to the convulsions of childhood and to epilepsy.
3. That only one factor in its production is constant, viz., a peculiar condition of the nervous system that may be designated as one of "unstable equilibrium," and that this factor is common also to the convulsions of childhood and to epilepsy.
4. That retention of urinary constituents when present vastly increases the tendency to convulsions in pregnancy, but that outside the conditions of pregnancy and childhood such retention is but rarely the cause of convulsions.
5. That nerve irritation—shock, emotion, violent pain, uræmic or other morbid condition of blood, &c.—is capable of setting up sudden vaso-motor spasm of cerebral blood-vessels.
6. That this spasm of blood-vessels causing sudden anæmia of the brain is the cause of the convulsions, and, I would add, of the consequent coma.

If this view of the etiology of puerperal convulsions be correct—and it is backed by facts and vouched for by men whose opinions are of weight—it leads naturally to the *Treatment*, and in fact furnishes an explanation of the success that has attended the employment of chloroform, ether, chloral, bromide of potassium, subcutaneous injection of morphia, and blood-letting. I do not see how this theory explains the supposed value of drastic purgatives.

Opium was employed long ago in this disease, and was recommended by Dr. Ewees, of Philadelphia, in 1825. Chloroform, ether, chloral were also promptly made use of on their appearance, and bromide of potassium on its virtue in epilepsy becoming known.

Wrixton, of Watford, in 1880, asked the question whether morphia would be appropriate. Just a word on the subcutaneous injection of morphia in eclampsia. It does not appear to have been employed much before this question was asked in the *Lancet* in 1880. It had been employed, however. Dr. Clark, in the *Amer. Journ. of Obstet.* of the same year, had drawn attention to the "strange tolerance of opiates" in this affection. Dr. Braun, of Stuhm, had published a case in 1879 in the *Berlin. Klin. Wochen.*, p. 385, in which a small dose of morphia, 0.02 gm., had not relieved the convulsions. Dr.

Trecoulat recommended the subcutaneous injection of gr. iss. every two hours, and said that he had never known the remedy to fail. Soon after this 21 cases were published by Smith, of Melbourne (15 cases); Beatty, Stockton-on-Tees (4 cases); and one case each by Harris, of Pendlebury, and Dr. Lucas, of this city. All these cases recovered. It appears, then, that we have in morphia injected subcutaneously a remedy certainly not inferior, perhaps superior, to any other yet employed in eclampsia. I have not yet had an opportunity of using it, but it is a remedy that will no doubt commend itself on many grounds.

Another remedy of comparatively recent introduction demands notice—I refer to pilocarpine. Bidder made use of it in 1872 with success in two cases. Vysin, of Olmütz; Breuss, Vienna; Triaire, Schülein, Braun, of Stuhm; Saenger, of Leipzig; and Hamilton, of Chester, have employed it in all 11 times. Of these 11, 4 died and 7 recovered, but in 9 out of the 11 dangerous symptoms of suffocation from œdema of the lungs came on, so that upon the whole we must conclude that pilocarpine, notwithstanding its undoubted power of diminishing arterial tension, is anything but a remedy to be commended in the treatment of puerperal eclampsia, as it appears that in every fatal case the patient died from the remedy, and not from the disease. Two other drugs that may have been already employed, although I have not met with any recorded instance of such employment, are nitrite of amyl and nitro-glycerine. They are remedies of proved value in epilepsy and some other spasmodic complaints, and I should certainly give them a trial, if opportunity occurred, as adjuncts to morphia, and as tending to prevent the need for very large doses of the opiate. (a)

In conclusion, I should like to mention one or two instances of the affection observed by myself.

The first was that of a woman in whom the premonitory eye symptoms were well marked. For two or three days before labour came on she could scarcely see at all, and after the first attack became blind, and remained so for about four days. In this case there was probably advanced kidney disease, from which recovery had not taken place after the lapse of two months, when I lost sight of her.

In the second case the attacks were apoplectic, or at any rate were complicated by apoplexy. The patient became hemiplegic, and never completely recovered the use of the affected side. This case occurred about fifteen years ago, and the patient still remains in this crippled condition.

The last I shall mention was that of most interest from a clinical point of view. I am sorry that I cannot find my notes of this case, so that I have to trust to too great an extent to memory. The patient was a very little woman, æt. 28, eight months pregnant of her second child. She had been subjected to a good deal of what may be termed domestic unpleasantness. Previous to this period—the end of the eighth month of pregnancy—she had suffered considerably from violent and persistent headaches, but the sight was not affected. I saw her on the evening of April 24th, 1877, when labour threatened. At 3 o'clock of the morning of the 25th I was summoned, and found she had had a convulsion. Labour did not seem to be progressing, and I did nothing but make use of the usual remedies for the convulsive attacks. No outward signs of pains were observed by me during the time I stayed with her, so that on making a vaginal examination, previous to leaving her for a short time, about 8 in the morning, I was extremely surprised to find the child expelled entirely. It was dead. Notwithstanding the birth of the child, the convulsions were no better, but kept returning at rather long intervals. There were no intervals of consciousness. About 11, I bled her to eight ounces, but with little effect. I then asked Dr. Dale to

(a) *Amer. Jour. of Obst.*, July, 1880.

(b) *Gazette Hebdomadaire*, 1872, vol. II., p. 481.

(a) In the discussion that followed the paper, Dr. Macdonald stated that he had employed nitrite of amyl in one case, and that it appeared to have the power of warding off the convulsions.

see her with me. Notwithstanding all treatment, the attacks continued until the evening of the next day, and lasted altogether about thirty-six hours, during which period she had about ten seizures. She still remained comatose. This condition of coma lasted till the 27th. At this date the case seemed absolutely hopeless. She was thoroughly exhausted by the violence and long continuance of the convulsions. For three days she had had no food or medicine except by the rectum, for the coma was so deep that the reflex irritability of the palatal and pharyngeal muscles was absolutely lost. Whatever fluids were put into the mouth, no efforts of swallowing followed. Nutrient enemata are at best but a poor substitute for gastric digestion, and although I have always made use of them in cases in which food could not be given by the mouth, I have never been able to satisfy myself of their great value. At this time death seemed so certain that my only expectation was to prolong life as much as possible. With this object in view, and to tide over time as much as possible, as I did not believe there was anything necessarily fatal in puerperal eclampsia itself, I determined to inject some food into the stomach. I procured a No. 12 male catheter, and by means of a piece of india-rubber tubing, attached it to a Higginson's syringe. I then mixed a breakfast-cupful of milk with an ounce of brandy, and as near as I could guess, a drachm of Liebig's extract of beef. For an epicure such a compound would perhaps not be palatable, but it was not intended to touch the palate of my patient, so that the flavour was a matter of indifference. I then passed the catheter into the stomach and injected the whole of the mixture, with the comfortable feeling that, at any rate, the poor creature would not die of starvation. If I were to say that the dose did wonders, I should not exaggerate. Within an hour consciousness returned, and from this time she was able to swallow. Her progress towards recovery was now uninterrupted.

The profound coma that follows these eclamptic attacks is almost certainly not due to compression of the brain from effusion of serum or œdema, as was formerly supposed, but to anæmia. If this be so, a ready explanation is offered of the remarkable and immediate change for the better that took place in my patient on the injection of food into the stomach.

I have since then attended her twice in confinement. The last time she suffered much from headache; but although I several times examined the urine, I could discover no trace of albumen. Both subsequent labours were perfectly normal.

(I ought to state that two gentlemen who took part in the discussion that followed the reading of the paper, Drs. Barr and Glynn, stated that they had repeatedly examined the urine of epileptics immediately after attacks, and had repeatedly found albumen. So that the opinion expressed above to the effect that epileptic attacks are not the cause of albuminous urine would appear to require modification.)

ON THE VALUE OF LACTOPEPTINE IN THE GASTRIC DISORDERS OF CHILDREN.

By AUBREY HUSBAND, M.B., C.M., B.Sc., F.R.C.S.Ed.,
Medical Officer to the Royal Dispensary, Edinburgh.

OF all the disorders to which young children are liable those affecting the digestive organs are at once the most common and the most fatal. It has been calculated from the Registrar-General's report that one quarter of the deaths among children under five years is due to diseases of the digestive organs, and this fatality is considerably greater under one year. The vague terms "Debility," "Atrophy and Debility," "Inanition," "Convulsions," which help to swell the reports of the infant mortality of this country all point to the inability to digest the food provided and to draw from it the nutriment required for the development of the growing infant. This mortality

is probably not due to any inherent complexity in the digestive organs of the child, but to the nature of the materials supplied as food, and it may confidently be asserted that the young of no other animal is subject to such a variety of dietetic experiments as that of man. Among the poorer classes of our towns these efforts to solve the problem of infant dietetics are unavoidable, and in most cases it is worse than absurd to lecture the people on the necessity for suckling their infants, or the keeping of their feeding bottles sweet and clean. It is not as a rule the feeding bottles that are at fault, but the materials placed in them, and which the force of circumstances compel the poor to use. Passing from these general considerations I would specialise one or two diseases which, from their constant recurrence at the Royal Dispensary, Edinburgh, cannot but fail to attract attention, and which, with the cordial assistance of Mr. Arthur E. Marsack, I was enabled to watch the effect of lactopeptine in their treatment. The cases were those chiefly of rickets, and of so-called infant atrophy, with dyspepsia and diarrhœa. The prevalence of rickets in Edinburgh and in Glasgow is most marked, and is to be attributed to the too early use of oatmeal porridge and other farinaceous foods. This opinion is of course most heterodox in Scotland, where attention is at once directed to the strength and vigour of the Highlanders; but it must be remembered that the two cases have nothing in common except in the use of porridge, for in these highland districts a large allowance of milk is taken with the oatmeal, whereas in large towns the supply of milk is scanty, and not of the best, even if it can be procured. These, again, the surroundings of the two classes are different, for whilst one has all the benefits of country life and fresh air the other is exposed to all the injurious effects of bad air and deficiency of sun light. The formation of an excess of lactic acid in the stomach of children fed largely on a farinaceous diet, and the irritation caused by it in the osteo-plastic or bone forming tissue of the long bones, as suggested by Wagner, together with the constant drain from the system of the salts of lime by the diarrhœa which, as a rule, accompanies the gastric derangements of children, is probably to be found the cause of rickets so prevalent in Edinburgh. It must further be borne in mind that the dread of large families, more keenly felt in large towns than in the country, causes women to prolong the period of lactation till pregnancy compels them to desist. Owing to the debilitating effects of protracted nursing the strength of the woman is greatly impaired, and her future offspring suffers in proportion. It is not, therefore, surprising to find an increasing want of vitality and vigour in each additional member of the series, and as the means of support do not increase in a proportionate manner to the number of children a marked tendency to infantile disease of an adynamic character followed with a high mortality is the result.

The following cases are of this type, and are recorded almost verbatim from the report of the gentleman above mentioned:—

1. C. D., æt. three. The little patient was brought by her mother to the dispensary with all the signs and symptoms of rickets. She had a heavy stupid look, the chest much contracted laterally, and the bones of both legs and arms much affected. She vomited occasionally, did not complain of any pain, but never smiled, and, in her mother's words, was "dwining away." She was ordered gr. v. of lactopeptine after each meal, and under this treatment the child gradually and then rapidly improved, the mother frequently expressing her gratitude for the change in the health of her little one.

2. M. W., æt. two. This child, when first visited, was found suffering with symptoms of gastric derangement, colic, vomiting, and loss of flesh. On inquiry the fact was elicited that the diet consisted of anything that could be obtained, from a piece of cheese to a bit of dried cod or a potato. As there seemed no chance of providing more suitable food for the child, it was hoped

that by means of lactopeptine the diet might be made more digestible and nourishing. Acting on this suggestion she was ordered gr. v. of the drug three times daily after food. The result was more favourable than was at first expected, and the treatment was combined as far as possible with regularity of habits, meals, &c. The little patient when last seen was quite well.

3. J. M., aged seven years and a half. This little lad appeared to be well cared for, but evidently of a strumous habit. He complained of no special symptoms, except that he always felt pain after taking food, and from the report of his mother was losing flesh rapidly. He could not take cod-liver oil. There were no chest symptoms. He was ordered gr. v. of lactopeptine as in the former cases. The treatment was continued for about a month, but before that time, however, he was able to take cod-liver oil without any return of the vomiting after each dose, which had before prevented its administration. He ceased to attend at the dispensary, and when visited was found to be quite well and able to go to school. The above cases, and several others which might be appended, serve to demonstrate the value of lactopeptine in the treatment of some of the gastric disorders of young children, and I may also state that I have found it of value in children far younger than those mentioned above. In two cases the children of a mother in the last stages of phthisis, the mother declared that the lives of her babes had been saved by its use. In these cases the doses are of course much smaller than those given above.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Reported by JOHN W. MARTIN, M.D.

Puerperal hyper-pyrexia—Suppression of the lochia—Abdominal tenderness—Distension—Headache—Restlessness and Insomnia—High pulse-rate, and weak, quivering pulse—Furred tongue—Anorexia and general malaise—Great prostration—Treatment—Result.

On Sunday evening, May the 6th, I was asked to see a Mrs. W., of Gloucester Street, Sheffield. She had been confined the previous day of her eighth child, and had been attended by a midwife, who, as far as I have been able to learn, is fairly qualified for her work, and intelligent. The labour was one of ordinary severity, lasting some eight or nine hours. According to the nurse's statement, the after-birth came away entire, and without traction on her part, in about twenty minutes after the child was born. Shortly after the delivery of the afterbirth there was a sharp dash of hæmorrhage, which lasted for 25 to 30 minutes, and by which the patient was greatly weakened. She got but little sleep on Saturday night, and suffered acutely from after-pains. On Sunday she passed, *per vaginam*, a mass about the size of a duck's egg, very firm in consistence, and closely resembling, as far as I could ascertain by a hurried examination, a fibroid tumour. I regret, however, that it was thrown away before I had the opportunity of making a more minute examination as to its nature and structure. If simply a clot, it was unusually firm in its consistence. On Sunday afternoon the abdomen became distended and very tender to pressure of any description, her cheeks flushed, the lochia suppressed, and her general condition such as to alarm her husband and friends. I saw her about 7.30 p.m. I found her lying on her back, scarcely able to move, every movement causing acute pain. Her face was scarlet, her eyes bright, and presenting a very restless, anxious expression. The tongue was heavily coated with fur, and there was complete loss of appetite. She complained of great thirst. The respiration was rapid and shallow. The skin was very hot to the touch; it was inclined to be moist and perspiring. The abdomen was greatly distended, and very tender to pressure or touch of any kind. I could not make out any unusual enlargement of the womb. The lochial discharge had ceased. The bowels had been well moved on Saturday. She was passing water freely, of a good colour, and free from deposit, or albumen. The pulse was 140 beats to the minute, weak and quivering under the finger, very

compressible. Temperature 106°2'. She complained of violent headache, and of the impossibility of getting to sleep. The patient is of medium height, stout, and of rather a flabby habit of body.

I ordered the nurse to syringe the maternal passages out well with warm water and Condy's fluid, and to repeat the syringing frequently; to apply a large turpentine stupa over the whole surface of the abdomen, following it up with frequently-repeated hot lined poultices, and prescribed the following mixture and draught:—

R Potass. nit., ʒiss.;
Sp. eth. nit., ʒij.;
Tr. aconiti, ʒj.;
Vin. ipecac., ʒiiss.;
Syrupi, ʒj.;
Aque chloroformi ad ʒviii.

M. ʒj. every hour and a-half for the first three doses, and then, every third hour.

At 12 o'clock she was to have—

R Potass. bromidi, ʒj.;
Liq. morph., ℥xxv.;
Hyd. chloral, ʒss.;
Syrupi, ʒj.;
Aque ad ʒij.

M. Draught as directed.

On Monday, May 7th, I found her better. She had passed a fair night, and under the influence of the draught had obtained several hours' refreshing sleep. The abdominal pains and tenderness were not so acute. The tongue was cleaner. Her skin was decidedly cooler and moister. The pulse had fallen to 120 beats, still weak, and with a slight quiver in it. The temperature was down to 103°. The face was not so flushed, and her general appearance was much improved.

At the evening visit there was but little change from the morning, with the exception of the thermometer, which had risen to 103°6'. She also felt sleepless, and seemed a little inclined to be restless. I ordered the draught to be repeated; other treatment to be continued.

8th.—At the morning visit I did not find her so well. The nurse had neglected washing with Condy the previous evening. The pain and tenderness over the womb had increased during the night, and the abdomen was greatly distended, and tympanitic. She had not passed a good night, and complained of severe headache. The bowels had not been moved since Saturday. The tongue was heavily coated with fur and thick slimy mucus. She complained of great thirst, and inability to rest in any position. The slightest movement gave her acute pain. The pulse was again 120 beats per minute, and very weak. The temperature registered 106°. Her face was flushed, and the skin was very hot to the touch, and perspiring. I ordered a good dose of castor oil to be given; fresh turpentine stupes to be applied, still keeping up the frequent application of hot poultices, and prescribed—

R Quiniæ sulph., ʒss.;
Acid. sulph. dil., ʒij.;
Tr. aurantii, ʒij.;
Sp. chloroformi, ʒiiss.;
Aque ad ʒviij.

M. ʒj. every 4 hours.

At 6 o'clock p.m., when again seen, the bowels had acted freely; the pain and tenderness with bowel distention were much relieved. The tongue was not so coated with slime. The pulse was 120, but stronger; and the temperature was down to 103°. She had only had one dose of the quinine mixture. A slight, slimy, foul-smelling discharge was noticed from the vagina. She was not so thirsty, flushed, or feverish. Draught repeated.

9th.—At the morning visit I found that she still maintained the improvement of the previous evening. Pulse 116, stronger. Temperature 102°6'. Face pale; general expression much improved. Free from pain and tenderness, and the distension of the abdomen greatly diminished. The amount of discharge from the vagina increased, colourless, and very offensive. Could detect nothing by a vaginal examination. I directed a close watch to be kept for the passage of any lump or mass, in case any portion of the placenta might have possibly been retained. The tongue was cleaning rapidly, and was well and firmly protruded. There was a marked improvement in her general expression and appearance. Took nourishment well, and was able to

move about freely. At the evening visit, the symptoms were the same as in the morning.

10th.—She had only taken half the draught, and had passed a good night, having enjoyed a good long, sound, refreshing sleep. She was free from headache. Face pale. The abdomen was soft and flaccid, and she could bear any amount of pressure over the womb without the slightest pain or tenderness. The discharge from the vagina continued to come in moderate quantity, and of the same character as recorded. The tongue presented a firm and clean appearance. The pulse had fallen to 108, and was much stronger and more resistant under the finger. The thermometer was down to 101.2°. The skin was cool, and firm to touch, and her general expression was much better and brighter than it had been from the commencement.

At the evening visit found her still improving. Pulse 104, and decidedly firmer. The temperature had fallen to 100°. Had two motions. Desire for food was returning. Ordered the other half of the draught to be taken at bed-time.

11th.—Had not slept so well; awoke frequently, and when asleep, dreamed heavily. In other respects, much improved. No pain, distension, or tenderness in the abdomen. The discharge from the vagina slightly increased; still of the same offensive character. The passages were kept well washed out. Nothing but the discharge passed. Tongue clean and firm. No thirst. Taking her nourishment freely. The pulse was down to 88 beats a minute, and firm to the finger. Temperature 99.2°. Ordered the mixture to be continued, and a whole draught to be taken at bed-time. Discontinued my evening visit.

12th.—Found her sitting up in bed at the time of my morning visit, looking pale, but bright, and free from pain. The pulse was 100 beats a minute; but I think this must have been due to the sitting up in bed. The temperature was down to 99°. The tongue was clean and firm. Appetite returning. She had had a good night's sleep. The discharge continued as before. The bowels had been moved twice. I ordered the poultices and draught to be discontinued, and the mixture to be continued steadily.

13th.—Slept well, and without having to take the draught. Felt better, and more herself. Skin cool and natural to the touch. Pulse firm, 88 beats to the minute. Temperature 97.6°. The discharge almost gone. Bowels had not been moved since Friday (11th). Tongue very lightly furred, but on the whole clean and firm. Desire for food increasing. No longer feels any thirst. The abdomen free from all pain or tenderness. Passing water well, and of a healthy character. The condition of the patient was one of healthy convalescence. I directed the medicine and washing out of the vagina to be continued.

14th.—Still improving. Pulse 80, firm. Temperature 97.2°. Discharge ceased. Appetite increasing. Slept well. Quite free from pain, tenderness, or distension. Mixture continued.

15th.—Convalescent. Tongue clean. Pulse 76. Temperature 97.8°. General symptoms improving rapidly. Bowels regular; appetite good; and beginning to feel that she wants to be out of bed.

17th.—Convalescent. Discontinued my attendance.

During the first few days of my attendance on this case the outlook seemed most gloomy. The fever was so high, and the prostration so severe, it did not seem as if she had power to rally. Hitherto I have been prejudiced against the administration of quinine when the tongue is loaded with a heavy fur, as I have always considered such a condition a contra-indication to its use. That prejudice has been swept away in this class of cases, where with the loaded tongue we have co-existent hyper-pyrexia. The result of its administration was most satisfactory.

On the 15th of May I was asked by the assistant of a brother practitioner who was away from home, and who had asked me to give assistance when required, to see a Mrs. H—, æt. 46, who had been confined of her fourth child on the 7th of May, after a fairly favourable labour, but who had subsequently developed symptoms closely resembling Mrs. W.'s case. The temperature at the date of visit was 106.2°; pulse 132; respiration 44, rapid, shallow. The abdomen was tender, but not distended. The lochia were suppressed; only a slight, foul-smelling discharge noticeable. Bowels acted regularly. The tongue was clean, but inclined to glaze. The patient was very thirsty, restless in the extreme, inclined to delirium, and unable to get to sleep. I secured the latter by giving her a draught

containing morphia, chloral, and potassa bromid., and placed her on grs. iv. of quinine every third hour, at the same time having the maternal passages well washed out with Condy's fluid and warm water, and applying turpentine stupes and hot linseed poultices to the abdomen. The result of treatment was most satisfactory. By the 19th the temperature had fallen to normal, and the pulse to 80 beats a minute. The tongue became natural, and all excitement and sleeplessness disappeared. I have since learned that she has done well, and is progressing satisfactorily towards restored health.

In both these cases the secretion of milk was very scanty. In Mrs. W.'s case the supply remains very poor. I do not know whether the quantity has increased in the case of Mrs. H.

I have given a faithful record of the symptoms. I do not attempt to dogmatise as to the real nature of the attack. Both patients were certainly in a very critical condition, and I think there can be no question as to cause and effect, between treatment and the results attained. In many respects the attacks differed considerably from what is laid down in text-books as typical of peritonitis. The pulse was not wiry and incompressible. There was not much nausea or vomiting. There was no painful respiration, nor were the knees drawn up, with raised shoulders.

If the attack in the first case was septicæmic, it certainly commenced very rapidly and very violently, and on that account is worth noticing; equally so if connected with the attempt to establish the flow of milk.

76 Brunswick Street, Sheffield.

THE UNQUALIFIED ASSISTANT SYSTEM

AND THE

ILLEGAL SIGNING OF DEATH CERTIFICATES.

(Continued from page 449.)

THE RISE AND PROGRESS OF THE SYSTEM OF EMPLOYING ASSISTANTS.—(Continued.)

THE resident medical, surgical, and obstetric officers at hospitals are usually either qualified or under the engagement to become qualified soon after their acceptance of office; and this engagement their teachers, who recommend them for appointment, guarantee them to be capable of fulfilling.

Charitable dispensaries as a rule nowadays do not permit the attendance of unqualified persons on their *protégés*.

If sick paupers and the recipients of alms have a claim to the personal advice of a qualified practitioner, much more has an independent working man, who pays that qualified practitioner to advise him. The smallness of the payment is no justification of his fraudulent receipt, and it is clearly a dishonourable pecuniary transaction to take the payment for the medical services of unqualified assistants.

2. Unqualified assistants are left in sole charge of patients.

Often by accident, often by the wilful act of the principal, an unqualified assistant is left in sole charge of the sick. More often still he is sent to see a patient in the first instance, and to decide the most difficult point a physician has ever to determine, namely, whether the sufferer has anything the matter with him, whether he ought to have any medicine or none. The larger the practice of the principal, the more often this is likely to happen.

The offending principals are sometimes men of good, sometimes even of high repute and having charge of public institutions, as in the following memorial of an unqualified assistant, the good faith of which is guaranteed:—

"Before I obtained any licence to practise, I worked for some time as an assistant. My first place was as resident at a lying-in hospital, where my principals were two gentlemen of high professional standing. They never interfered in any midwifery case but one, where it was necessary to perform a perforation of a child's head; an operation from which, I confess, I shrank. We had a bad epidemic of puerperal fever; and for fear of carrying contagion, one of my principals, who was attending some ladies of high rank, never came near the place. The other, whose wife was expecting her confinement, was very cautious, never examining any patient sufficiently to criticise my treatment; and some of the fatal cases were not seen by him at all. I paid fees for instruction, but learned nothing from those who received them; my most noticeable

acquirement from my experience being a misplaced self-confidence, which it has taken me many years to unlearn.

"My next place was under a surgeon to a dispensary, in whose name I took charge of the women and children during his absence for six months on the continent. I attended alone cases of pneumonia, tubercular meningitis, miscarriage, typhoid fever, and small-pox, and gave burial certificates in my own name, the regulations for registration not being so stringent as now. My object in undertaking these responsible posts was to gain a knowledge of practice; but I am sure that the time was in a great measure wasted, and that much more knowledge would have been picked up had the usual hospital curriculum been completed first."

The abuse of leaving an improper person in sole charge is most commonly perpetrated where so many assistants are kept at once that it is physically impossible to exercise superintendence. For example, you have the letters of a late unqualified assistant, who, on going to his place, found himself engaged with two others also unqualified, but with some previous training, and a fourth (a retired miner) without any. "Stephen," the miner, was set up in a branch in opposition to one "Willie," a bone-setter, and also a retired miner. It is believed that four is by no means the largest number of assistants that are engaged at once; indeed, in the place above described, five were afterwards taken, though not during the four years that the writer stayed. This occurred a few years ago; now larger numbers are reported, but not with the full details above given.

The following letter from a colliery agent of great experience gives an impartial sketch of the system from a non-professional point:—

"It is usual in colliery districts for a legally qualified medical man to be appointed surgeon to several collieries, which may be several miles apart. He generally lives in a central position, and appoints assistants to live near the collieries. The assistants are in most cases unqualified men, but, on the whole, give satisfaction when they are steady. In case of an accident occurring at any of the collieries, it is the rule to send for both the assistant and his employer, and the latter exercises a supervision till the patient recovers, or otherwise. I have never heard a workman complain or object to an assistant on account of his not being qualified. The people are well looked after when the chief surgeon is competent and moves about amongst assistants and patients.

"There are cases, however, where the appointment of surgeon is given to a man living ten or more miles from the colliery, and who never, or very rarely, visits it but leaves everything to an assistant, who certainly ought to be, but is not always, a qualified man. There are other cases within my knowledge where unqualified men are practising, nominally as the assistants of qualified men, whose names they have permission to use; but these latter live many miles from the place and have nothing whatever to do with the practice. This latter class I have known to give certificates on many occasions in a most improper and careless manner, and thereby cause loss to clubs and other relief funds. It would no doubt be better to have all medical men legally qualified, but the amount of remuneration obtainable in many colliery villages would not tempt a properly qualified man to settle there. The system of having unqualified assistants acts fairly well where they are what the name implies, and where the chief surgeon lives within a reasonable distance, exercising some control and occasional supervision; but in all other cases it is, in my opinion, objectionable."

The duty delegated to an assistant is sometimes still further sub-delegated. There is a so-called "Provident Dispensary" in a manufacturing town of 26,000 inhabitants, "conducted by the qualified assistant of a neighbouring country practitioner, who keeps his unqualified brother on the premises, and is supposed to come over daily to see urgent cases;" and a county coroner has known death certificates to be regularly signed by an unqualified assistant's wife on behalf of the principal or cover.

In midwifery cases it is almost impossible to avoid leaving an assistant in sole charge where the number of patients is large. Yet in this department of practice unqualified men are extensively employed, and, in fact, are often paid extra at so much a case as an attraction. They are required to use obstetric instruments, and are objected to if they cannot do so. Naturally they become in time very expert accoucheurs, and are found in the end more useful and self-reliant than qualified men in the capacity of assistants. It can hardly be expected that an ill-paid man should resist the temptation of

practising on his own account, which is very common. Some times, indeed, he does it in a very criminal manner. A case has been put into my hands in which an unqualified assistant, acting as an abortionist, had a verdict of "wilful murder" found against him by the Coroner's jury, but was got off at his trial. His clever solicitor informed a neighbouring surgeon (the correspondent) that his client, after imprisonment, got "more bespeaks than ever for midwifery cases."

3. *Encouragement is given to the issue of false certificates and to forgery.*

The further career of the last-named man illustrates other dangerous courses into which unqualified assistants may be led. They are called upon to supply death certificates for those who die under their care. The demand is usually provided for by obtaining the signature of a registered practitioner; and the operation is technically called "covering."

Mr. Graham, coroner for Chester Ward, co. Durham, says that the rule is to send for the qualified medical man when the patient is moribund, so that he may be able to say he has attended. But if he cannot say so, and an inquest is held, the coroner takes the evidence of the unqualified man as to symptoms, and then that of the qualified as to cause of death. At Fence Houses, Durham, we are informed by a clergyman that an unqualified man "signs his death certificates with his own name, *pro Dr.* —, a relation who resides in Manchester." And in a neighbouring parish of 5,000 inhabitants, mostly colliers, the colliery clubs have appointed as their responsible medical officer an unqualified man, nominally an assistant to a registered practitioner at Durham, who gives his name for the certificates. This statement is attested by the vicar, who laments the condition of things, but sees no way out of it inasmuch as the unqualified men are upheld by the overruling influence of the viewers. An explanation of this last fact seems to be afforded by a communication from Staffordshire, which says that the colliery "doctor" often attends gratis the viewer's family. A bargain of such a sort is easier made with an unqualified than with a qualified man.

At a manufacturing town in Yorkshire, two men who had for some time been unqualified assistants to practitioners in the town with large club practices, took shops, fitted them up as druggists' shops, and consulting rooms, visited patients at their own homes, and signed death certificates, using the name of qualified covers at Sheffield (six miles off), who had never seen the cases. Their practice was stopped by threatened action of the Apothecaries' Society, and they have both since become qualified and honest. It would appear from the details reported at an inquest in Middlesex ("Standard," August 21, 1882), that the signer of certificates gets a certain sum per certificate, which he enters as income in his books.

Mr. Alexander Blyth, Corresponding Secretary to the Miners' Permanent Relief Fund, says that some of the medical men have their names lithographed to be used by their unqualified assistants.

Dr. Eddison, of Leeds, has known of a packet of death certificates being signed in blank, and left to be filled up by an unqualified assistant, while his chief went on a holiday.

Mr. Crofton Maynard, coroner, Durham, reports that this practice is also resorted to in his district. And in the report of an inquest in the "Standard" newspaper of October 13, 1882, it is described as common in London.

A careful bookkeeper has been known to enter in his ledger the charge for the certificate before the patient's death, so that it may be handed over immediately it becomes due. (See inquest, in "Eastern Morning Herald," February 4th, 1882.) A letter, dated February, 1875, from Major Graham, Registrar-General, complains of these practices, but there is reason to believe, from cases reported in the daily papers, they are still extensively carried on, and are encouraged by the unwillingness of the Registration Department to prosecute. But the "cover" sometimes turns scrupulous or spiteful, and refuses his protection. Then the assistant sees an easy way out of the difficulty by committing forgery. The person whose previous history was recorded was detected in this offence while acting as an assistant, and under a proper sense of the scandal so created, the medical school at which he was entered as a pupil expelled him. He boldly entered at a larger school, fulfilled his curriculum, qualified, and is now on our *Register*.

It must be understood that not only death certificates are required by clubs, but also certificates of illness. By these ignorantly, carelessly, or fraudulently given, the funds of such societies are seriously injured. To show the importance of this matter, it may be mentioned that the Miners' Permanent

Relief Fund at Newcastle receives over 12,000 certificates annually.

In their anxiety to obtain qualification, unqualified assistants are sometimes led to employ false schedules of school attendance. A case is reported in confidence, but on undoubted authority, of "a very good man" who got "signed up" without ever having attended a single lecture or dissected a single part (being occupied as an assistant); yet, with the help of a grinder, he succeeded, after several years of indomitable perseverance, in obtaining a qualification. His false schedules were signed in one division of the kingdom, he qualified in another, and is practising in a third.

4. *The employment of unqualified assistants lowers the character of the profession.*

Instead of acquiring the thoughtful ways of a responsible dealer with human life, an unqualified assistant often does his work swiftly and mendaciously. His offhand manner is looked upon with favour by the roughs in the neighbourhood, who familiarly hail him by such nicknames as "Sailor Jack," "the Black Doctor," the "Colonel," &c., not maliciously, but in token of good fellowship. Yet he is put forward by his masters as their representative, the *alter ego* of guaranteed knowledge and skill, and spoken of to the patients as "the doctor," and is usually designated by that title in the newspaper reports of inquests. He himself joins in the misrepresentation by using the commercial pronoun "we" in speaking of himself; and visitors to the poor are often told that in a bad case there are three or four "doctors" in attendance, who prove on inquiry to be one registered practitioner and his assistants. The virtual personation involved in sending an unqualified assistant to attend a patient to whom the principal has been summoned is not only in professional eyes an infamous fraud, but is looked upon by the public as untradesmanlike, thus causing a grave scandal. In an inquest held at Manchester in September, 1881, the coroner remarked that "he was surprised any medical man should lend himself to such deception (*Manchester Evening Mail*, September 23, 1881). And again, in the *Eastern Morning Herald* of February 4, 1882, a jury is reported as saying that the "system" was unsatisfactory in every respect, to themselves personally, and to the neighbourhood.

(To be continued.)

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

A MEETING of the Surgical Section of the Academy of Medicine was held in the Albert Hall, Royal College of Surgeons, Mr. J. K. BARTON, President of the College, in the chair.

Mr. STOKES, Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

LIVING SPECIMENS.

Mr. WHEELER—1. Amputation at shoulder-joint; 2. Amputation of foot (Syme's); 3. Excision of elbow.

Mr. STOKES—Excision of knee-joint.

Mr. THOMSON—Parts removed in case of refracture of a patella.

SPECIMENS EXHIBITED BY CARD.

Mr. STOKES—Photographs illustrative of results obtained after excision of the knee-joint:—1. Excision for pulpy thickening of synovial membrane; 2. Excision for faulty ankylosis; 3. Excision for ulceration of cartilages and pulpy thickening of synovial membrane; 4. Excision for caries and extensive disease of soft structures; 5. Excision for synovial thickening; 6. Excision for caries and pulpy thickening; 7. Excision for pulpy thickening and commencing caries.

Mr. SWAN—Excision of knee-joint.

Mr. THORNLEY STOKER read a paper on

REMOVAL OF THE THYROID GLAND IN CASES OF BRONCHOCELE.

He detailed the case of a boy on whom he had himself operated, the disease being the most extensive of which he could find any operative record. The tumour extended nearly from ear to ear, and hung down nearly as low as the navel. He removed two-thirds of the mass, comprising the right lobe

and isthmus, in March, 1882, and the remainder on the left side a year later. Complete recovery followed the first operation; but the patient died five days subsequent to the second from pulmonary thrombosis. The patient was incompletely cretinah, but developed greatly after the first operation. Mr. Stoker showed that while ten or twelve years ago the ablation of the thyroid gland for disease had been practically abandoned, during the last decade a revulsion of surgical feeling on the subject had occurred, and that now it should be held justifiable as the result of late experience to perform the operation, the patient so desiring, not only in cases where the disease threatened life, but where discomfort or disfigurement existed and minor treatment had failed. He emphasised his argument by quoting a series of cases from the practice of various surgeons, commencing in 1871 with Dr. William Warren Greene, of Boston, whom he regards as the pioneer of the most modern opinion on the subject. The freedom with which the operation had of late been undertaken was, he thought, in part due to the results of Listerism, and in part to the greater boldness which increased knowledge and improved appliances have generated in the surgeons of our day.

Dr. R. M'DONNELL said he was present on both occasions. The first operation might be regarded as quite successful, and taught the lesson that in cases of the kind the operation was justifiable. The second had a fatal issue from a cause not necessarily connected with the operation.

Mr. CORLEY stated that in his hospital practice some years ago, a similar case arose, where the pressure of a large thyroid gland became so great as to render operative interference necessary; it was shortly after P. H. Watson published his paper; and having written to him for details, he got a copy of it. He was forcibly struck with the solemnity of the undertaking to remove the thyroid gland, as an operation in which the surgeon must be prepared in some cases to see the patient die on the table. Hence he did not think Mr. Stoker had dwelt sufficiently strongly on the magnitude of the operation.

Dr. H. KENNEDY drew attention to the treatment of thyroid tumours by the seton, and mentioned a case in which at the end of some months the disease was entirely cured. Such a measure as that would be more justifiable in the first instance than the terrific operation described by Mr. Stoker.

Mr. THOMSON was sorry to differ from Dr. Kennedy in his suggestion as to the surgical practice in the case Mr. Stoker had detailed. Whatever use the seton might be in some cases of small thyroid tumour, it would be useless in Mr. Stoker's case, in which the vessels were of enormous size.

Surgeon-Major HAMILTON remarked that ten or fifteen per cent. of the population in the Himalaya valleys suffered from bronchocele. Sometimes 20 and 30 coolies might be seen climbing mountains 2,000ft. to 3,000ft. high, carrying enormous loads, 50lbs. or 60lbs. weight, and each wearing a tumour. It seemed extraordinary that the pressure on the larynx did not interfere with their breathing. By rubbing in biniode of mercury ointment with a spatula as they lay on their backs in the sun, they always obtained relief. The great benefit seemed to be derived from doing it in the sun. He had seen many cases so treated, and had not known any of the men to die from it. When at Simla, an epidemic of bronchocele broke out—no less than 60 cases—and the same treatment was adopted. In the Himalaya valleys syphilis was supposed to be the cause, and the people lived on inferior food in overcrowded houses badly ventilated.

Dr. FOY instanced the case of a woman, æt. 22, who had a very rapidly-growing thyroid tumour which caused her inconvenience both in breathing and swallowing. It became urgently necessary to do something, and he applied a blister on the back of the neck with the best result. A seton was subsequently inserted, and the gland in a short time assumed its normal size.

Mr. STOKES endorsed what Mr. Stoker had said regarding the inutility of using any mild measures in such cases as he had described; but in those referred to by Dr. Kennedy, Dr. Foy, and Surgeon-Major Hamilton, the tumours were probably of extremely simple structure. He recollected two cases in which merely tapping, followed by a weak solution of tincture of iodine, sufficed. The employment of setons found little favour in his eyes. In Mr. Stoker's case nothing short of the very heroically-performed operation adopted would have given the patient the slightest chance of recovery. The introduction of air into the veins was avoided by the application of the double ligature, and dividing the veins between them. Thus the operator need not be apprehensive of the fatal accident

which he had heard and read of, but had never witnessed, namely, the so-called canalisation of veins.

Dr. BENNETT, following in the line Mr. Stokes had taken, thought that some of the observations made were directed to a class of thyroid tumour which had never been the subject of removal; for instance, acute enlargement of the gland; such tumours as occur in epidemic goitre; or acute goitre in pregnancy or menstruation. He did not suppose any surgeon would propose to operate, knowing that if the epidemic influence, or the particular exciting cause, such as pregnancy or menstruation, was past, the tumour, troublesome and dangerous at the time, would become quiescent, or even disappear. The point that struck him as difficult of explanation was how it was possible to make the tumour disappear by biniodide of mercury. If the sun was a powerful agent, then they had not that, the second element of the treatment in this climate. It would be interesting to know whether such treatment was successful in the case of Europeans in India, or was the success confined entirely to the natives. He was inclined to think, however, that to expose a European for a sufficient time to cure him of the goitre, the result would be to kill him with the sun. The great desideratum was to diagnose exactly the kind of tumour that ought to be the subject of removal.

Surgeon-Major HAMILTON observed that it was the smallest tumours which were very often radically cured. Europeans were treated for enlargement of the glands the same as the natives. The only danger was from sunstroke, but this was avoided by placing the upper portion of the body in the shade.

Mr. WILLIAM STOKER mentioned that similar treatment was the rule in Switzerland.

Mr. WHEELER said none would think of extirpating the thyroid gland, when due to anæmia, or the thyroid enlargement of menstruation, or what might be termed the cystic bronchocele; but he was of opinion that bronchocele of large size, and when very chronic, if causing dyspnoea, dysphagia, and pressure on the jugular vein, and vertigo, ought certainly to be removed. He did not agree with Mr. Hamilton in thinking that the rays of the sun were essential to act on the biniodide ointment. Such practice was common in India, but the heat of the fire would answer very well.

Mr. THORNLEY STOKER replied.

Mr. SWAN read a paper on

THE PRIMARY CONSIDERATION OF ORTHOPÆDIC CASES.

He explained certain allusions to affections not strictly to be termed orthopædic by stating that they very frequently were seen by surgeons practising that branch of surgery. He detailed some cases of caries in the tarsus of children, showing the differences of opinion that existed respecting the treatment to be adopted in this affection, and the modified conclusions respecting excision of diseased structures arrived at by Sedillot, Erichsen, T. Holmes, Gross, and others. From a prolonged observation of a limited number of examples made by himself, and from the results obtained from the records of Dr. H. Culbertson and Dr. Virgil Gibney, of New York, he arrived at the following conclusions:—1. That the advantages of excision in tarsal caries do not appear to be so obvious as to warrant their frequent application; 2. That as there is no evidence of amyloid degeneration of viscera in long-continued suppuration of the tarsal joints, that conservatism in its widest signification may be specially applied to disease of these structures; 3. That an anchylosis of the tarsal articulations, a result of the generation of plastic material during the course of the disease, will occur, but that this process, though diminishing the mobility of the foot, will leave it fairly useful. In referring to angular curvature of the spine, the impossibility of predicting the amount of deformity was maintained. The supervention of paraplegia on the other hand might be confidently anticipated to occur only in caries of cervical or upper dorsal vertebrae. So far as the paralysis was concerned, the prognosis might be stated to be usually favourable. The probability of the development of abscess was shown to be chiefly the result of motion, and not necessarily the sequence of extensive gibbosity or even extensive implication of tissue. Scoliosis was stated to be exceptional in an early stage, an incurable affection, and one in which prevention was better than remedy. Mr. Swan showed an apparatus which he stated he had used with success in early curvatures. In equino varus or section of all resisting structures was insisted on, and relapses were said to be often due to a neglect of this rule. More congenital distortions of the feet were divided into—1.

Those the result of nervous lesions; 2. Those depending on ligamentous relaxations; 3. In the treatment of deformities of the lower limbs depending on essential pneumo-mimetic affections; and 4. Those of traumatic origin. Paralysis as usually adopted, whether by counter-irritation, localised galvanism of Duchenne, massage, or the Swedisch movement cure, the writer did not put much faith, but held a strong opinion on the utility of the direction of volition to the limb whilst by proper means maintaining symmetry, holding that the development of the use of the unaffected muscles even remotely attached to the member established a compensating power, and believing that in many cases some of the fibrillæ of muscles the bulk of which were paralysed retained contractile power.

Mr. WHEELER was of opinion that Mr. Swan was not sufficiently explicit in his paper with reference to the disease of bones of the feet, and the excision of bones, &c. A tolerably accurate diagnosis of the extent of the disease could be formed by observing where the disease commenced. There were four distinct synovial sacs in the foot. Hence it would be easily understood that the extent of the disease would be greatly influenced by its starting point; for instance, it would be plainly much more limited if starting in the os calcis than in the cuneiform bones. Complete excision of the os calcis was not a very common operation. The results in two cases he had were most satisfactory; a third, however, was not quite so successful. He deprecated the use of the gouge as dangerous and unscientific practice, especially in disease of the ankle-joint. It was not always easy to say when the entire disease was removed. He agreed with Mr. Swan's statement that in talipes equino varus the anterior tibial muscle, and if necessary, the tibialis posticus, should be cut before the tendo Achilles.

The PRESIDENT remarked that the partial removal of carious bone was exceedingly unsatisfactory. Although Mr. Wheeler had condemned gouging, his experience of it had been attended with marked success.

Mr. SWAN replied.

The Section then adjourned.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of the Medico-Psychological Association was held at Bethlem Hospital on Friday, 18th May, Dr. D. Hack Tuke in the chair. Drs. Wigglesworth, Macfarlane, and Blair were elected to be members of the Association, after which an interesting paper was read by Dr. Sutherland, on "Prognosis in Cases of Refusal of Food," in which he advanced certain propositions based upon the circumstances under which, according to his experience, prognosis would be good or bad. A long and interesting discussion followed, embracing the causes of the refusal of food, the best method of administering it—whether by the stomach pump, the nasal tube, or the enema—the beneficial effect of enforced rest at the first appearance of the symptoms, &c.; several of the speakers concurring in the desirability of varying the treatment.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, MAY 7TH.

JOSEPH WALKER, M.D., President, in the Chair.

AMONG the casual communications were two cases brought forward by Mr. F. Canton and one by Mr. Ackery, in which a horizontally directed wisdom tooth had caused partial absorption of the roots of the second molar in front of it. In none of the cases had this condition of things given rise to pain, the discovery being made accidentally.

Dr. DYCE DUCKWORTH ON

THE CHARACTERS OF THE TEETH IN PERSONS OF THE ARTHRITIC DIATHESIS.

Dr. DUCKWORTH began by saying that, although it was the fashion of the present day to disbelieve in diatheses, he was himself a firm believer in their existence. He believed that there existed an "arthritic" habit of body, or diathesis, and that this comprised at least two branches—the rheumatic and the gouty. These were essentially distinct; they might be mixed, but one would not produce the other. The rheumatic diathesis was more widely spread than the gouty, but the latter was most common in the south of

England, and especially in London. The result of a somewhat extended series of observations, made with no other view than to record exact facts with reference to this disease, had convinced him that the teeth of the gouty were, as a rule, remarkably strong, well-enamelled, enduring, and remarkably free from decay. On this point he differed entirely from the opinions expressed by Dr. A. Carpenter in a paper recently read before the Society. Dr. Carpenter's statement that gouty people were specially prone to caries might be true of those who lived carelessly and intemperately; but he held it to be an undoubted fact that persons who inherited gout but were themselves temperate, of whom there were many, had generally strong and sound teeth. The modifying influence of a mixed diathesis, especially the existence of a strumous taint, would account for most of the exceptions to this rule. Dr. Duckworth then referred to the tendency which existed in persons of gouty inheritance for the teeth to be worn down, so as sometimes even to open the pulp cavity; he had never heard this satisfactorily explained. Another peculiarity of such people was the tendency to shed perfectly sound teeth, the loss being due to a process of absorption of the alveolus. Gouty people were no doubt liable to attacks of alveolar periostitis, but he knew of no careful observations confirming Dr. Carpenter's statement that "lithate of soda was deposited in the circumdental membrane." The characters of the teeth in persons of the rheumatic habit of body were certainly less distinctive than those which could be noted in the gouty, but as a rule such persons had strong, well-enamelled teeth. Dr. Laycock, of Edinburgh, had called attention to one remarkable exception to the rule that the teeth of persons of the arthritic diathesis were large and regular. This was a tendency for one or more of the lower incisors to be pushed forward, an irregularity to which the name of "buck teeth" had been given. It might not appear till middle life, and he was quite at a loss to suggest any explanation for it; he could only call attention to it as a well-observed fact. In conclusion, Dr. Duckworth complimented the dental profession on the progress it had made in its endeavours to repair the ills consequent on habits of luxury. It was a great thing that the study of dental pathology was now founded on a thorough knowledge of the anatomy and physiology of these organs; it would be a further important step when the great doctrines of diathetic predisposition and of scientific physiognomy were carefully worked out and applied to practice. He hoped that his communication might have contributed something to this end, or might at least enlist the interest of dental surgeons in the subject.

An interesting discussion followed.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

BACILLI IN TUBERCULOSIS.—At the Académie de Médecine M. Cornil read a paper on the rôle of bacilli in tuberculosis, in which an account was given of the result of forty cases minutely examined for the microbe. In a case of tubercular meningitis a great quantity of bacilli were discovered, as well as in a tubercular affection of the peritoneum, where the granulations were the seat of a large number of them. In two cases of pulmonary phthisis several were found at the root of the lungs. Tubercular affections of the kidneys furnished in four cases abundant microbes. In conclusion, M. Cornil said that the result of his researches would admit of three divisions:—First, that in which the considerable number of bacilli of tuberculosis explains the genesis of the lesions which constitute that affection. The propagation of these micro-organisms by the blood and lymphatic vessels was fully proved by being in the interior of the vessels. This class of facts is entirely in accord with the experiments of Koch, who, by injecting the bacteria of tuberculosis into different animals reproduced constantly that disease. In second series of facts the bacilli characteristic of tuberculosis

are by no means numerous, but there exists always one or several in the giant cells, that is to say, in the midst of the tuberculous granulations. In a third class of cases, which referred to chronic tuberculosis, the bacilli were only found in the walls of the cavities and the ulcerated bronchi.

RESECTION AND DESTRUCTION OF THE LUNG BY THE THERMO-CAUTERY.—M. Koch, well known by his researches on the microbe of phthisis, has been hardy enough to attempt an operation which certainly will not have many imitators. The operation, already practised twice by the German *savant*, however, seemed to answer his expectations. The first case was that of a man of 24, with an enormous cavern in the right lower lobe, purulent expectoration, night sweats, and rapid wasting. M. Koch thought himself justified in employing the cautery, and for that purpose a piece of the sixth rib was resected to allow the instrument to penetrate into the pulmonary tissue until it reached the cavity, the walls of which were freely cauterised, and the instrument withdrawn. The reaction following the operation was but slight, and the expectoration of purulent fetid matter diminished considerably. Four days afterwards the thermo-cautery was brought into requisition a second time for the same patient. A piece of the eighth rib was cut away, and the cautery introduced as before. The patient continued to bear the operation well, and at the end of ten days the cautery was used for the third time, and with apparent success, so that the Professor proposed attacking one by one the several cavities existing, but the patient succumbed the following day. The second case was that of a woman, who presented a cavity the size of the closed hand in the upper lobe on the right side. Four inches of the rib situated over the lesion were resected, which permitted the cavity to be cauterised. Expectoration ceased, and granulations of a good nature took the place of the eschar. The patient succumbed a week afterwards from septicæmia, which, according to M. Koch, existed already before the operation. M. Koch thinks that the destruction by the thermo-cautery of limited portions of the pulmonary tissue will be found beneficial in those forms of chronic gangrene of the lung accompanied with abundant expectoration of putrid matter, in acute pulmonary gangrene where the mortified tissue cannot be eliminated, as in gun-shot wounds, when foreign bodies fall into the small bronchi and not being able to find their way out again by any means, produce destruction of the neighbouring tissue, and finally, in those forms of fetid and putrid bronchitis where dilatation of the bronchi cannot be demonstrated, and in the rare form of localised pulmonary phthisis.

At the Bristol Police Court on Friday last, Mr. E. J. Neale, a potatoe merchant, was fined £6 and costs for the non-vaccination of his children. It was stated that Mr. Neale had already paid about £90 in fines and costs in respect of the same children.

OUR contemporary, the *Globe*, states that the Queen has been graciously pleased to approve of the honour of knighthood being conferred on Alfred Roberts, Esq., honorary secretary and consulting surgeon to Prince Alfred Hospital, Sydney, New South Wales. We do not find the gentleman named on the *Register*; moreover, consulting surgeons do not usually occupy the post of secretary, nor are secretaries to hospitals generally selected for the honour of knighthood. There is a mistake somewhere.

WEDNESDAY, MAY 30, 1883.

THE CHARGES AGAINST THE ARMY MEDICAL SERVICE.

THE charges made more or less vaguely at the time against the working of the Army Medical System in Egypt have now been formulated. The list of allegations against that branch of the military service is an imposing one. Let us consider a few out of many thus adduced, bearing in mind the fact, as we do so, that to the chief military officer whose complaints against that system are now loudest the service gives the credit of having himself been the prime mover in regard to the abolition of the former "dual" system, and the substitution in place of it of the so-called "system" which now has broken down under his own hands! for, as we hope to show, no incrimination of subordinate officers can in reality remove the ultimate responsibility from the actual chief. This fact is familiar in the popular proverb regarding the workman and his tools. It is important to bear the circumstance in view that, in the Egyptian campaign at the beginning of the present century, shortcomings precisely similar to those now recorded took place in the hospitals there established on the general, or staff "system;" that the system so named was forthwith abolished—regimental hospitals taking their place—and that from the very time that change was effected the sick were amply supplied with all requirements, the result being that mortality among them was small, except among the troops attacked with the plague. In the

recent expedition the Indian portion of the force had its medical and hospital systems as nearly on the old regimental system as they possibly could be, considering that the "unification" scheme had recently been forced, very much against the teachings of experience, upon the military and medical authorities in India. Throughout the entire campaign no hitch of any kind occurred in regard to the medical department with that force; on the contrary, doolies and bearers from it are said to have been utilised in conveying wounded from the field for whom no transport whatever was available with the English portion; drugs were, moreover, given for the use of the hospitals of the latter, which otherwise would have been absolutely without medicines. These facts clearly indicate that, whatever mal-administration or shortcomings have now been dwelt upon in the Proceedings of Lord Morley's Committee rested alone with that portion of the "system" which is portrayed at length in the "Soldier's Pocket-book," and elaborated under the chief direction of the author of that publication.

Let us now come to particulars. The nursing was bad. If so, who is to blame for the "general" and short service systems which combine to deprive the sick soldier of the services of the old trained orderly in his regimental hospital—to whom nearly every man in that regiment was personally known, and by whom he was known? To whom is the service indebted for the change under which young men with no special aptitude for nursing are entrusted with the care of men, strangers utterly to them, and for whom they care nothing? Moreover, what inducement has such an "orderly" to devote himself specially to his vocation with zeal? Pensions are almost completely things of the past. All these things are out of the hands of medical officers.

At Ismailia bread was bad, and hospital diets badly cooked. If this was the case, the thing was the result direct and alone of the action taken by the Commander of the expedition in having failed to communicate with the principal medical officer at Alexandria before suddenly moving the force *vid* the Canal. Thus it happened that, while the troops were taken to Ismailia, the regular establishments necessary for the working of, and belonging to a "dietet" hospital for them, remained at the original base, a field—that is "non-dietet"—hospital being all that accompanied them. Regiments had too much duty of other kinds on hand to be in a position to send "rations" for their men "gone sick" to such a hospital, or they were proceeding in advance, and so had not the means of doing so. Under any circumstances, whatever change in the "system" was demanded at the time to meet the requirements of the emergency could and ought to have been ordered on the spot by the Commanding Officer. Medical officers are specially excluded from all "executive" functions.

At Cairo sick men were without bedsteads; nor had they mosquito nets or little fans wherewith to keep the flies from their faces. Medical officers had made "requisitions" for these articles upon the department charged with the duties of supply, but the requisitions had not been fully complied with. The Commander found fault, not apparently with the department actually concerned, but with

the medical. Instead of giving his written authority for the latter to usurp the functions of the "store" branch of the service, as he might have readily done, he appears to have absolutely taken no means such as were in his own hands to supply the patients with the articles in question. It is vain, therefore, as it is unfair and invidious, to throw dust in the eyes of the public by an attempt to cast upon other shoulders than his own defects in the first instance due to his own pet system of unification, and in the second to the fact that he took no steps such as were in his power to remedy defects. As to the duties of "supply" being thrown upon the medical department, the proposal, if indeed meant in seriousness, must end in failure. The thing is simply impracticable. Every wheel of a machine must revolve in its own groove; if each be expected to run in some other than its own proper groove, the result is easy to comprehend.

It is stated that a medical officer refused to attend sick soldiers except at regular hours. This assuredly is a charge of the most serious kind, and one that reflects upon the medical department by itself and alone. But, if true, why was the accused officer not brought to book at the time and on the spot? It was most culpable on the part of the military officer in command to have slurred it over for a single hour. Yet he nurses his wrath to keep it warm, until, within the walls of a comfortable room in Pall Mall, he tells his story under circumstances where his charges can neither be publicly met nor contradicted.

THE ROYAL COLLEGE OF SURGEONS, IRELAND, AND THE CERTIFICATE SYSTEM.

THE questions upon which the Fellows of the Irish College of Surgeons will have to decide when they hold their annual meeting on next Saturday are probably more critical and will demand more firmness of purpose and courage in action than any which have been submitted for their judgment for many years past. The moment has come for dealing a decisive blow to the time-dishonoured corruptions of medical teaching in Ireland, and we confidently expect that the Fellows of the College will not hesitate—once and for all—to deal that blow with such effect as to destroy for ever the disreputable traffic in fictitious certificates which has degraded Irish teaching and enriched unscrupulous persons in times not long gone by.

The first step forward towards honesty of Irish teaching has been voluntarily taken by the Council of the College, who have, during the past year, not only reformed the arrangements of their own school, abolished the credit fee system, and so discouraged apprentice-farming, but have, with an honesty of purpose which does lasting credit to them and the College, pledged themselves to regulations for ensuring the *bona fides* of study, which regulations cannot be evaded without positive falsification or by guilty connivance at their evasion.

That these safeguards against fictitious certificates have not been too soon adopted most of the Fellows know well, for most of them have been fully cognisant that, heretofore, certificates of "diligent" attendance have

been, to all intents and purposes, sold for so much cash to students who made no pretence of having earned those testimonials by occasional bodily presence, not to say by "diligence."

Since the Fellows met for their last annual assembly, the sham certificate system has entered upon a new phase, and it is this new departure which especially demands the attention and action of the College. Certain teachers who have hitherto covertly provided at so much per parchment the certificates with which certain students deceived the College as to their attainments, have been so far encouraged by the toleration afforded to them that they have boldly claimed the right to continue the issue of these certificates to a crowd of students whom they cannot pretend have fulfilled the requirements of medical education or of the College.

They have presented themselves at the doors of the College backed by a number of young men who came to tell the Council that they did not, and would not, study their profession during the day, being employed in earning a living elsewhere; that, as they could not visit their hospital, and could not perform dissections, or sit out lecture instruction at the hour set apart for that purpose, they would insist on being admitted to the College examinations without doing so; and would, if refused, make Ireland too hot for the College by means of newspaper denunciation and Scotch competition.

These teachers—through the mouths of their student representatives—have declared that they will continue in spite of the College (and they have continued) to issue the full tale of certificates of study, granting such documents upon a more or less frequent presence of the student at semi-grinds delivered in the evening from 7 p.m. to 11 p.m. to young men who have been engaged all day in counting-houses and shops, and they have refused either to set forth a definite number of attendances in the way approved by the Council, or to allow the student to give any pledge of the truth of the statements put forward in his name.

The Fellows of the College are now called upon to speak with an authoritative voice on this matter. The outgoing Council has done as much as it dared do to make its curriculum of education honest, but it has been subjected to a form of intimidation which is still in full force, and which will assuredly be exercised again with renewed strength the first time that they attempt to enforce the prohibition against sham certificates and night lectures, and we therefore appeal to the Fellows to encourage the Council by their approval, and to strike with vigour against the certificate trade, which, we are convinced, they are ashamed to think of as part of the system by which surgeons and Fellows have hitherto been made.

That system, in its most recent expansion of night lecturing, will be defended by two arguments—first, that these courses of study are unnecessary, and therefore, that the attendance of the student on them is useless, burthensome, and valueless; second, that the young men who obtain these certificates by the night lecture expedient are industrious and intelligent, commendably ambitious, and ought to be encouraged rather than tabooed.

Neither argument has, in our eyes, the least force, because we hold that if they be true the objections should be satisfied in some other way than by forcing these students to pay for fictitious papers.

If any part of the curriculum of study be unnecessary, and an incubus, let it be cut away at once, and without mercy, but let it not continue to be recognised only as a sham for the benefit of one or more teachers, and a fraud upon the student who has to pay for the paper which represents it. As long as any given course is indispensable to a thorough practical knowledge of the profession it should remain, and not a moment longer, and while it remains it certainly should not be evaded.

As regards the *personnel* of the night students, we speak with as much respect, or more, than that entertained by those who are engaged in certificate dealings with them. Many of them are, in our opinion, the right stuff of which surgeons might be made, and they deserve and shall receive from us every encouragement to advancement in their profession by honest work. But they have no right to ask to be made surgeons by trickery and evasion—not to be allowed to go out into practice in necessary ignorance of their business, simply because they could not spare time to learn it.

All colleges concur in requiring some other evidences of medical education than an examination, and they must continue to do so, or else enlarge the examination so as to make it an all-sufficient test. Until they so enlarge it no one should pass out into practice upon the guarantee of an examination and a bundle of falsified papers which are called certificates of attendance, and no young man, however earnest, should reasonably expect exemption from this rule.

Whatever course the Fellows of the Irish College of Surgeons may pursue on Saturday, we are truly glad to believe that the days of sham certificates, credit fees, apprentice-farming, and night-lecturing (as the means to these ends) are numbered, and we invite the College to give them a hearty and definite dismissal.

THE METROPOLITAN BOARD OF WORKS AND ITS WORK.

There is scarcely a ratepayer within the limits of the mighty township over which the Metropolitan Board of Works reigns supreme, who is not keenly alive to the economical considerations of his relation to the Board. A good many persons, however, take even a greater interest than that which has its origin in monetary reflections, in the proceedings of the assembly to whose hands is committed the governing of our civil life; and hence the appearance of the Board's *Annual Report* is regarded as an event of not inconsiderable importance. The yearly volume for 1882 has just recently been issued; and while in nothing is it inferior to its predecessor so far as the magnitude of the operations detailed is concerned, it is in some respects endowed with even an exceptional degree of interest.

It is satisfactory to be told, almost at the outset of the Report, that during the period with which it deals progress has been made in the very necessary work of

providing new sewers sufficient to carry away the overflow of storm water, and so to prevent recurrence of those distressing floods so prevalent in past years in various parts of London. The result thus gained is not merely relief from inundation on behalf of the poorer riparian population, but a higher immunity both for them and their adjacent neighbours from the certain developments, in the way of ague, sickness and rheumatism, of those conditions favoured by periodical district flooding. In addition to sewer construction, also, as a means of preventing future floods, certain other works, in the way of raising wharf banks and walls along threatened parts of the river, have been carried out in accordance with the Board's directions, under the powers conferred by the Thames Floods Prevention Act, 1879. It is, therefore, possible at last to feel that the period is rapidly approaching in which the exhibition so frequently witnessed in the past of flooded-out riverside tenements will live only in the memories of those who have been familiar with such occurrences in the last decade or two.

Under the heading of "Metropolitan Improvements," a long list of important works is detailed, involving for their completion the expenditure of vast sums of money, but conferring at the same time very substantial advantages on Londoners and visitors to London, in the way of commodious and handsome roadways and breathing spaces.

In furtherance of the aims of the Artisans' and Labourers' Dwellings Acts, numerous additional buildings have been completed and opened during the year, and a lengthy list of sites is given which will ere long be covered with these houses of the working classes, as a result of the action of the Peabody trustees and other associations. In carrying out its street improvements, the Board complains that it is a good deal hampered in consequence of the inadequacy of the Acts and Amending Acts under which its action is pursued. To this cause is attributed very much of the slowness of action it exhibits in fulfilling its own plans for improvement, the conquering of obstacles which can be opposed to it under existing Parliamentary decisions being sufficient to interfere with speedy work. Under the increased powers given to the Board, however, by an Amending Act, which became law in August last, it is hoped that much more expeditious labour will be possible; and in this Report the Board name no less than four schemes for the widening and improvement of thoroughfares, which Parliament has been requested to sanction during the present session. That the erection of houses for the working classes in the spaces created by the Board of Works confers an immense benefit on those for whose occupation they are designed, it is impossible to gainsay. Without them the daily labourers must be content to live in squalor and misery, packed away in a reeking room, one of numerous lodgers in a most unwholesome dwelling. That these older houses, in fact, are unwholesome we need but little assurance; and it may be safely asserted that in every situation where industrial dwellings are now to be found in London, there were formerly nothing but the most wretched tenement houses—hotbeds of sickness and contagion. Happily such dens are

fewer now than they were before the genius of Charles Dickens first excited the utterance of public opinion on one of the worst evils of our age; and during the year 1882 a direct representation to the effect that a site needed clearing was made only in one instance—viz., by the Medical Officer of Health for Shoreditch. The difficulty, too, that was once almost insuperable—that of dealing with the families dispossessed of their dwelling places by the progress of improvements—is now no longer a grave obstacle to advance in this direction; existing dwellings and the daily increased facilities for suburban residence have deprived the reproach of cutting the labourer off from his work of all the point it undoubtedly possessed prior to railway extension and increased building operations.

On the subject of "Parks, Commons, and Open Spaces" the Report is very satisfactory. During the year three spaces, or a total superficies of 72 acres, have been brought under the control of the Board. The total acreage of public common ground now ruled by this authority amounts to 1,769½; and each separate park, common and heath is cared for and utilised under able direction to the utmost possible extent for public good. The amount of benefit conferred by these extensive and numerous breathing spaces is not easily computed; but it is beyond all manner of question that they are of infinite avail in maintaining the health of the great city in and around which they are situated.

The subject of infant life protection is very properly now brought within the scope of the Metropolitan Board of Works; and in the last Report the following paragraph occurs in that part of it which dwells on the action taken under the Infant Life Protection Act, 1872:—"At the beginning of the year there were 24 registered houses (in which infants were kept for hire) in the metropolis; there are now 33, and other applications for registration are under consideration. The registered houses have been inspected 438 times, and have been found to be conducted in a satisfactory manner, except in four cases, in which it was found necessary to caution the occupiers of the houses, with the results that in three of the cases the matters of complaint were set right at once, and in the other the keeping of infants was discontinued." Even the Metropolitan Board of Works could scarcely engage in a more meritorious labour than this of protecting the lives of the young and helpless.

We leave the Report now, with the recommendation that all should read it who are interested in the improvement and government of the metropolis.

Notes on Current Topics.

The Registrarship of the Irish Branch Council.

THE five gentlemen who compose the Council have been precipitate in their haste to appoint to the office vacated by the death of Dr. Steele, and have filled the office within ten days of that event, and without taking any adequate means to open the post to competition. They were indeed guilty of the indecency of circulating

a call to consider the appointment before the late Registrar was in his grave; and it was, we believe, only on the remonstrance of one or two of the members that the others consented to give a week's breathing time before putting some one in his vacant seat. For this unseemly haste—somewhat redolent of a job—there was no excuse whatever. The office which became actually vacant by Dr. Steele's death had been practically vacant for months previously from his illness, and through that period the business of the office—never very onerous or important—had gone on, as we believe, without any slip whatever, and might well have been allowed to go on in the same way until something was known of the future duties and emoluments of the office, and some opportunity afforded for competent persons to send in their applications.

We should like to hear some tenable excuse for this new-born activity of the Branch Council; for until some better reason for such precipitation is forthcoming, the Council is under the suspicion of having snatched at the opportunity to get into its hands the appointment of the new Secretary of the Medical Board for Ireland, which is to be created by the Medical Bill now before Parliament.

By the terms of this Bill the Registrar of the Branch Council in existence at the date of the passing of the Bill becomes Secretary of the Medical Board. He will, in that capacity, become at once the most important medical functionary in the whole of Ireland; for he will be charged with the organisation of the final examinations for the whole of Ireland; will have to manage the visitation of examinations held by all the licensing bodies in that division of the kingdom; he will, in fact, jump into duties of which no one at present can guess the extent; and will, of course, receive increased emoluments of unknown amount.

We say that this wholly unnecessary election, by a dying council of five, at ten days' notice, and with only a pretence of advertising the vacancy, is either a gross job or an unhappy blunder, and that it is liable to be construed into an attempt to seize the right of appointment which properly belongs to the new Medical Board. Whether the gentleman appointed is, or is not, fit for the functions to be discharged in connection with that Board is not the question in dispute. No matter what his qualities may be, the Branch Council, in our opinion, has no moral right to force him upon the body who are to have the administration of the new state of affairs.

It may be that some private understanding was arrived at with the new Registrar that the appointment shall be *ad interim*, and only for the period up to the formation of the new Board; but we doubt whether any such compact would have any validity if it has any existence, and, in any case, the appointment made now must operate greatly in favour of the individual selected, and against other candidates for the secretaryship of the Medical Board when that office comes to be filled. We shall take care that the subject is brought under the notice of those who have charge of the Bill, in order that, when the Committee stage is reached, something may be done to restore to the Medical Board in Ireland the right of appointing its own secretary.

Lectures at the London College of Surgeons.

THE lectures for the present year will be resumed to-day (Wednesday), by Mr. Henry Power, F.R.C.S., the subject of the three lectures being "The Lachrymal Apparatus and Accessory Organs of the Eye;" these lectures will be continued on June 1st and 4th at the same hour. Mr. Frederic S. Eve, F.R.C.S., will deliver, on the 6th, 8th, and 11th of June, three lectures "On Cysts and Cystic Tumours in General;" and Professor Jonathan Hutchinson, F.R.C.S., will conclude the course for the present year by delivering, on the 13th, 15th, 18th, 20th, 22nd, and 25th of June, six lectures, "On Certain Diseases of the Tongue."

Quinine in the Treatment of Whooping-Cough.

DR. W. THORNTON PARKER, Surgeon, United States Army, writes most favourably of his experience of the use of quinine in the treatment of whooping-cough. He gives teaspoonful doses of a solution of quinine of four, six, eight, or even ten grains to the ounce, every two hours, and finds that it gives *almost immediate relief* to the little sufferers. This method of treatment was brought from Germany to New York by Dr. Dawson some five years ago, and used by him with great success in the wards of the Hospital for Children in New York city, then under his care. Dr. Parker questions Dr. Dolan's assertion (in his Fothergillian essay on Whooping-Cough) that the course of the disease could not be controlled by treatment. His experience leads him to believe that in quinine, in the dosage recommended, we have a remedy capable of exercising control, and even of cutting short the disease.

Can Animals have Syphilis?

THE question whether it is possible for animals to suffer from syphilis has often formed subject of controversy among surgeons; and even the test of experiment has not always settled the matter satisfactorily. Prof. Neumann's is the latest attempt to solve the problem, and his results, as published in the *Central Zeitung*, are thus summarised by the *New York Medical Record*:—"The experiments were made with the greatest care, the virus being taken directly from the diseased person and introduced into the body of the animal. The animals operated upon were retained under observation for considerable periods of time after inoculation had been performed, but in no case did any results obtain other than such as would naturally be expected to follow from introduction of an irritant material into the tissues. Nothing bearing any resemblance to a chancre was noticed. The subjects of the experiments were three apes, three rabbits, a horse, a hare, a white rat, a marten, and a cat. Fifty-four inoculations were performed in all, and as the grand result of his repeated experiments, Neumann forms the conclusion that syphilis is a peculiarly human disease, and is not exhibited or contracted by the lower animals."

THE Hospital for Sick Children (Great Ormond Street, London), is in a more flourishing condition than many of its compeers. Last year its income was £10,678, and its expenditure only £9,800.

Feline Test for Defective Sewer Pipes.

AN ingenious Boston woman is credited by the *Medical and Surgical Reporter* with the following:—Suspecting the existence of some defective piping, and bearing in mind the great fondness that cats have for the smell of valerian, she borrowed a couple, and shut them up in the room where she suspected leakage took place. Having provided herself with some oil of valerian, she poured it into the highest basin in the house, and proceeded downstairs to watch the result. She was gratified to find that both manifested a preference for a certain spot in a closet near where a waste pipe ran; on further inspection a complete separation of the pipe was discovered.

Guy's Hospital.

A PORTRAIT of Sir Astley Cooper, the distinguished surgeon of Guy's Hospital, has recently been presented to that institution by Mr. R. Clement Lucas, the senior assistant-surgeon. It is a very excellent copy by Mr. J. L. Wimbush of Sir Thomas Lawrence's celebrated painting in the possession of the Royal College of Surgeons, and was copied by the permission of the Council of the College. Sir Astley, who was surgeon to George IV., obtained his baronetcy for removing a tumour from the King's head. He was a bold operator, and on one occasion ligatured the aorta; but he is best known by his work on fractures and dislocations, and his treatises on the testis and breast. By his influence the united schools of Guy's and St. Thomas's became separated, a change which proved very disastrous to the latter hospital and very beneficial to the former.

Women Doctors for India.

THE project for introducing medical women into Bombay is now fairly established, upwards of 40,000 rupees having been already subscribed for this purpose. The *Hindoo Patriot* states that the scheme includes the bringing out of women doctors from this country; the establishment of a dispensary for the poor; medical education for female students, through the Grant Medical College; and, finally, the establishment of a hospital for women and children. A Parsee has offered a lakh of rupees to build a hospital of the latter description.

Professional Confidences.

THE Legislature of the State of New York has decided that "no person duly authorised to practise physic or surgery shall be allowed or compelled to disclose any information which he may have acquired in attending any patient in his professional character, and which information was necessary to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon." It is difficult to reconcile this pronouncement with the fact that in New York any physician is liable to be clapped into jail and fined £10 if he does not give public notice that his patient is suffering from infectious disease.

THE Royal College of Physicians of London will hold a *conversazione* at the College on some evening during the season, most probably in June.

The Annual Meeting at the Irish College of Surgeons.

THE general meeting of the Fellows at which the Annual Report of the Council is presented to the College will take place on Saturday next, and is likely to be largely attended, and to afford an occasion for lively discussion. The Council has, we understand, discarded the old form of the report, and will submit the narrative of its proceedings and the statement of its accounts in a much more comprehensive and intelligible shape. It is likely that the policy of the College with reference to the Medical Bill will be debated, and that an effort will be made to induce the College to assume a position of hostility to the measure, which we venture to anticipate will not prove successful.

The proceedings of the Council with reference to Night Lectures and fictitious certificates may also—in all probability—come under discussion, and the Fellows will be asked to give their sanction to an amendment of the College's charter to enable examiners and professors to be elected by the entire Council instead of—as at present—by seven councillors selected by lot. Professor Thornley Stoker will move the following resolution:—"That in the opinion of this College the present method of electing professors and examiners is unsatisfactory, and that the Council be recommended to seek for such alterations in the charter as shall enable these elections to be made by the vote of the entire Council or such part of it as may be present; not less than two-thirds of the whole number, including the President or Vice-President, to constitute a quorum for election purposes." It will also be moved "That it be recommended to the Council to obtain an alteration of charter to render professors and lecturers in medical schools eligible for examinership."

THE COUNCIL CLUB DINNER

will be held in the College on Saturday evening. The club consists of all present and past officials of the College, councillors, examiners, and professors, and of such guests as they may invite.

THE ANNUAL ELECTION

of Council and officers will take place on the following Monday, between one and three o'clock. Mr. Wheeler, the Vice-President, Surgeon to the City of Dublin Hospital, will assume the presidential chair in succession to Dr. Barton, whose period of office expires, and Dr. Bennett, Professor of Surgery in the University of Dublin, becomes Vice-President, unopposed. Dr. Corley, Surgeon of the Richmond Hospital, and Lecturer on Surgery in the Carmichael College, announces his intention to seek the Vice-Presidency in June, 1884, when Dr. Bennett is promoted to the Presidency. For re-election to the Council of the College the whole of the outgoing members offer themselves, and, in addition, several Fellows present themselves as candidates. The following names have already been sent to the College Registrar:—Dr. Cameron, Professor of Chemistry in the College, and Superintendent Medical Officer of Health for Dublin; Mr. Baker; Dr. Austin Meldon, of Jervis Street Hospital; Dr. Kendal Franks, of the Adelaide Hospital; Dr. Fitzgibbon, of the City of Dublin Hospital; Dr. J. B. Story, of St. Mark's Ophthalmic Hospital; Dr. Hayes, of Stevens' Hospital; Dr. Carte J.P., Surgeon to the Royal Hospital and Kil-

mainham Prison; Sir Robert Jackson, late Inspector-General, A.M.D.; Dr. Coppinger, of the Mater Misericordie Hospital.

Stimulants in Workhouses.

DURING the past week a special report has been presented to the guardians of the parish by the medical officer of the Milton Union Workhouse, near Sittingbourne, in Kent. Dr. C. H. Fisher, the official in question, has delivered himself of the remarks contained in his report in answer to the statement made by a certain guardian, who complained of the indiscriminate administration of stimulants in the infirmary. As a matter of fact, only eighteen of the sixty-three inmates were on the wine list, but a few others of the aged and infirm were allowed small quantities of beer and porter. The report is possessed of considerable interest, however, apart from the merely statistical details it presents, on account of the emphatic manner in which Dr. Fisher states in it, as a result of long experience, that in dealing with the aged poor of the malarious district where his duties lie the free administration of stimulants in the more serious cases is imperatively demanded. The stimulants question has received so much prominence of late that every contribution to it of this description may be instructive.

Ship Surgeons.

IN a leading article printed in the *Shipping Gazette* of May 11th are to be found the most ample proofs that could be required of the vital importance of remedying existing chaos respecting ship surgeons. The article in question is intended to be a reply to the unanswerable charges brought by Dr. Irwin and his fellow-objectors to the conditions which now regulate service on board ship. The writer, however, has most unconsciously, it may be, but none the less absolutely in consequence, exposed the utter danger and weakness of that which he is ostensibly defending—viz., the *status quo*. We cannot enter into an analysis of the whole article, or indeed of any great part of it; nor can this be necessary, since no single proposition it broaches is capable of being for a moment accepted by any one who is acquainted with the facts. The following quotation will suffice:—"We agree in thinking that the doctor's inefficiency is, perhaps, one cause of the high mortality; but shipowners engage the best men they can get, the service performed being tolerably well paid," &c. This terrible admission, that shipowners engage the best men they can get, at little more than journeymen's wages, is, unfortunately for our contemporary's logic, the very strongest proof, taken with high death-rates, that nothing less than compulsion will ever induce such economising owners to pay the salary of a doctor who, instead of being the "best they can get," at £10 a month, will be the most highly qualified and experienced among younger practitioners. The question is, after all, one of pounds, shillings, and pence when reduced to its elements; and in the end coercion must, we suppose, be had recourse to, in order to overcome the many scruples reflected on the owners behalf in our contemporary's purposeless and foolish criticism of Dr. Irwin's and our own utterances.

The Irish Branch Council and the Sham Certificate System.

THE following correspondence has passed between the Branch Council and Dr. Jacob in reference to the letter addressed by him to the General Medical Council on the subject:—

Branch Medical Council (Ireland),
35 Dawson Street, Dublin,
May 11, 1883.

SIR,—The General Medical Council has referred hither your letter of 9th April, 1883, respecting attendance on lectures by medical students in Ireland for inquiry and report. I am therefore desired by this Branch Council to request you to be so good as to inform me whether you are prepared in reference to the letter before quoted to furnish the Branch Council for Ireland with particular information regarding any medical school or hospital in Dublin which has practised the irregularities of which you complain.

I am, &c.,
H. HOUGHTON, for Registrar.

Dr. A. H. Jacob,
23 Ely Place, Dublin.

23 Ely Place,
May 15, 1883.

SIR,—I acknowledge receipt of your letter of May 11, on behalf of the Branch Medical Council requesting me to state whether I am prepared to furnish the Branch Council with "particular" information respecting any medical school or hospital in Dublin which has practised the irregularities of which my letter to the Medical Council complained.

In reply thereto I beg, with every respect for your Council, to say that, having called attention to practices which have long been notorious, and to the evidences of the existence of those practices which are to be found in the Minutes of the Council, in its reported proceedings, in the Dublin newspapers and in the records of public bodies to which I have referred, I do not feel called upon to become the accuser of individual schools or hospitals, or to stigmatise by name members of the profession who have obtained their qualifications by participation in these practices. I cannot presume to instruct the members of your Council, all of them much better informed than I can be respecting medical teaching and school administration in Dublin, as to facts, the accuracy of which is within the knowledge of every school Registrar, and most medical teachers in Dublin, nor can I admit that proof of these assertions contained in my letter hangs upon the evidence of their truth in particular instances.

I regret, therefore, that I cannot give a more satisfactory reply to the request of the Branch Council than to refer them, for confirmation of my statements to—

a. The extracts from Minutes of the General Medical Council referred to in my letter.

b. The Minutes of the Royal College of Surgeons which contain the record of 94 students having claimed to attend night lectures on the ground that they were otherwise engaged all day.

c. The reasons which the Reverend Dr. Haughton can give for having, in his capacity of Medical Registrar of the University of Dublin, refused the certificates of a certain Dublin School.

d. The files of the Dublin newspapers—especially of the *Freeman's Journal* for the month of December, 1882—which contain a voluminous correspondence on night lecturing.

e. The evidence which your Council may readily obtain from medical teachers in Dublin as to the existence, past and present, of these practices.

The issue of certificates of "diligent" attendance to persons who did not, and could not, pretend to have so attended, is, indeed, practically undisputed.

I am, &c.,
ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

MR. W. E. WILLIAMS, F.R.C.S. Ed., has been placed on the magistracy of the County of Monmouth as a Justice of the Peace.

Society for Relief of Widows and Orphans of Medical Men.

At the annual general meeting of this Society, held a few days ago in the rooms of the Royal Medical Chirurgical Society of London, Mr. Charles Hawkins, F.R.C.S., in the chair, Dr. George Johnson was elected a vice-president, *vice* Sir Thomas Watson, Bart., deceased; and Mr. Cooper Forster, Mr. Garman, Mr. Freeman, Dr. Garrod, Dr. Grigg, and Mr. Warrington Haward were elected on the Council in the place of the six seniors who retired, and Mr. Upton, solicitor to the Society, and Mr. Croft, F.R.C.S., a benefactor, were elected honorary members. From the report and statement of finances read, it appeared that 18 new members had been elected in 1882, 9 had died, and 3 had resigned or ceased to be members. Six new widows had been added to those already receiving grants, 4 had died or become ineligible for further assistance, leaving 60 on the books at the end of the year. One fresh orphan had been relieved, 5 had become too old for further assistance, and only 5 remained on the funds. A sum of £2,871 10s. had been distributed in grants during the year, and the expenses had been £190 6s. 9d. The receipts available for the payment of grants and expenses had been £3,061 16s. 9d., the balance on receipts and expenditure being £130 16s. 9d. No legacies had been received during the year. Regret was expressed by many members present that so few medical men availed themselves of the benefits offered by the Society, especially since the alterations of the by-laws had made so great an addition to the income allowed to a widow (from £50 to £80), and had in so many other ways increased the powers of the Society to render assistance to the widows and orphans of deceased members. The secretary stated that the increased radius of the Society (now twenty miles round Charing Cross) had, as yet, made little or no difference in the number of the members—only 370 having joined out of 4,500 eligible in the metropolitan area. A vote of thanks to the chairman and the editors of the medical press closed the proceedings.

Treatment of Goitre.

EVERY improvement in surgery which successfully replaces a large and risk-attended operation by one of a simple and non-dangerous character, must necessarily be regarded in the light of an advance; and in this way a modification of the plan pursued in radical treatment of bronchocele, and which was advocated on Friday last at the meeting of the Clinical Society of London, is freely deserving of general recognition. The operation as described by Mr. Sydney Jones, F.R.C.S., consists in excision of the isthmus of the thyroid instead of extirpation of one or both lobes of the organ; and in a case in which he recently adopted it the proceeding was the most successful possible. A curious consequence of the operation, and on which Mr. Jones laid especial stress, is the invariable atrophy of the gland substances which ensues when the isthmus is taken away; and this fact has not been permitted to pass unnoticed by those Continental surgeons who have led the way in devising and adopting this new operation. That it is new to at any rate a majority of English surgeons is fair to assume, since the

most recent exposition of English surgery, the revised Holmes' "System," is silent in regard to the method. Its obvious advantages, however, so little require to be enforced that no one could be found on Friday to dissent from the opinion that it offers a manifest mode of simple relief in many instances where the vastly dangerous plan of total extirpation would, but for it, be attempted; and in all cases of small fibrous bronchocoeles, which by tightening and pressure produce alarming dyspnoea, the simple and easy operation suggested by Mr. Jones will in all probability be henceforth received as the only legitimate first proceeding open to the practical surgeon.

Parkes Museum.

ON Saturday last His Royal Highness Prince Leopold, Duke of Albany, re-opened the Parkes Museum of Hygiene in its new home, Margaret Street, Regent Street. Captain Douglas Galton, C.B., read the history of the Museum from its commencement, and addresses were delivered by Professor Tyndall, the Archbishop of York, Sir Chas. Mills, Sir Spencer Wells, the Duke of Albany, &c., and the proceedings were witnessed by a considerable number of visitors.

Blood Globules.

WURTZ, in his *Chimie Biologique*, says that in man the average volume of a red globule is 0.00000072 . According to Viewordt and Welcker, a cubic millimetre of blood contains about 5,000,000 red globules. The blood of women contains less. In ten litres of blood the number of globules would be about 50,000 milliards; and the superficies of these globules has been said to be 2,816 square metres.

DR. JULIUS ALTHAUS has been elected a Corresponding Fellow of the New York Academy of Medicine.

MR. ARTHUR W. BROUGHTON, a surgeon practising at Batley, has been fined £5 and costs for unlawfully making a false certificate of death relating to a person he had not seen.

THE Australian *Medical Gazette* gives some of the methods employed by the aborigines of Central Australia to prevent conception. One mode is to make an opening into the male urethra just anterior to the scrotum; another is to slit up the entire urethra, so as to entirely destroy the urethral canal from the scrotum to the base of the glans penis.

THE coronership for Enniskillen having fallen vacant by the resignation of Mr. Gilbert, the appointment is sought by Dr. Gamble, of Enniskillen; Dr. Gilbert, son of the ex-coroner; and Dr. Leeper, of Kesh. The choice of a coroner is in the hands of the Parliamentary electors of the district, who have not the least knowledge—not the least care—as to the suitability of any candidate. Religion and politics settle the question.

THE highest annual death-rates last week in the large towns from diseases of the zymotic class were—From whooping-cough 1.6 in Leicester, and 2.1 in Hull; and from "fever," 1.0 in Newcastle-upon-Tyne, 1.3 both in

Wolverhampton and Sunderland, and 1.6 in Preston. The 30 deaths from diphtheria included 17 in London, 5 in Glasgow, 3 in Edinburgh, and 2 in Birmingham. Small-pox caused 4 deaths in Newcastle-upon-Tyne, one in London, and one in Leeds.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their populations, were—Bolton 12; Bristol 14; Leicester, Huddersfield, Brighton 16; Halifax 17; Edinburgh, Derby 18; Norwich, Bradford, Nottingham 19; London, Sheffield, Birmingham, Birkenhead 20; Salford, Sunderland, Wolverhampton, Portsmouth 21; Cardiff 22; Blackburn 23; Plymouth, Manchester, Newcastle-upon-Tyne 24; Liverpool 25; Leeds 26; Dublin 29; Oldham, Preston 30; Hull 31; Glasgow 35.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Bombay 30, Brussels 31, Amsterdam 24, Rotterdam 30, The Hague 24, Copenhagen 33, Stockholm 26, Christiania 15, St. Petersburg 41, Berlin 25, Hamburg 31, Dresden 30, Breslau 34, Munich 33, Vienna 37, Prague 43, Buda-Pesth 39, Rome 35, Torino 31, Venice 27, Lisbon 32, Brooklyn 20, Philadelphia 21, Baltimore 22. By an unusual coincidence no returns were received from Paris, New York, Madras, or Geneva.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

DOUBLE EXECUTION IN GLASGOW.—How long the brute lingers in humanity! Last week the moral feeling of the great city of Glasgow was shocked by a double execution, with its inhuman and demoralising concomitants. The crime which led to this was evidently the result of a preliminary altercation: one of the men murdered, it was alleged—and there was no reason to doubt the allegation—first fired, and the second criminal fired in dread of being fired at. Since their condemnation the fate of the convicts excited widespread pity, and it was hoped that the Home Secretary would not turn a deaf ear to the petition of 10,000 people, many of them highly influential, of thirteen of the fifteen jurors who found them guilty, and of the magistrates of the City of Glasgow. The *Glasgow Herald* and the *Daily Mail* pleaded for the exercise of mercy, while the *Glasgow News* characteristically called for blood. Against two things we must here protest, in common with our contemporaries, in the first place, viz., that these unfortunate men should have been kept in suspense as to their fate until within fifteen hours of their execution; and once more we have to protest in the interests of public morality against the eagerness displayed by the press in furnishing the public at the earliest possible moment with the disgusting details of public executions. The shortcomings of human nature should ever be kept in the background, and to present them as our daily newspapers so wantonly do, nay, to thrust them on the public mind and attention, is subversive of public good, and unworthy of the influence which newspapers possess in moulding public taste. Under present circumstances it is a matter for congratulation that newspaper reporters are excluded from executions.

ABERDEEN.—CHAIR OF MEDICAL JURISPRUDENCE.—There are now eight candidates in the field for the Chair of

Medical Jurisprudence in the University of Aberdeen, vacant through the retirement of Dr. Alexander Ogston. They are Dr. Robert Beveridge, Dr. Frank Ogston, Dr. Robert Garden, Dr. Angus Fraser, Dr. John Urquhart, and Dr. Simpson, Medical Officer for the City Aberdeen, and Dr. Matthew Hay, and Dr. H. Aubrey Husband, Lecturer on Medical Jurisprudence in the Edinburgh Medical School. The appointment rests with the University Court. Dr. Husband's claims to the Chair seem to us of a high order, and we believe his election would prove highly beneficial to the University.

UNIVERSITY OF ST. ANDREWS.—We understand that at a recent meeting of the Committee on University Legislation, it was agreed to appoint Principal Tulloch, Dr. Caesar, Professors Birrell, Knight, and Pettigrew, Dr. Cleghorn, and Dr. Laing as a deputation to wait upon the Lord Advocate and other influential members of Parliament in connection with the Universities (Scotland) Bill; and at the same meeting it was resolved to take early action for raising subscriptions towards the better endowment of the chairs. The feeling is that a sum of £5,000 or upwards may be obtained in the county of Fife, and that then subscriptions will also flow in from a wider area. It is proposed shortly to organise measures and machinery for the purpose of making the necessary appeal to the public.

THE REGISTRAR-GENERAL'S RETURNS.—From the last returns of the Registrar-General for Scotland the death-rate in the eight principal towns during the week ending with Saturday, the 19th May, was shown to be 26·9 per 1,000 of estimated population. This rate is 0·8 above that for the previous week of the present year, and 4·7 above that for the corresponding week of last year. The lowest mortality was recorded in Aberdeen, viz., 15·7 per thousand; and the highest in Glasgow, viz., 35·0 per thousand. The mortality from the seven most familiar zymotic diseases was at the rate of 6·3 per thousand, or 1·4 above the rate for the previous week. Measles continue to be the most fatal miasmatic disease, the mortality therefrom being greatest in Glasgow. From acute diseases of the chest 111 deaths were registered, or 10 less than in the previous week.

GLASGOW.—HEALTH OF THE CITY.—The recent high death-rate in Glasgow has attracted considerable attention, and the last fortnightly return of the Medical Officer (Dr. Jas. B. Russell) is of considerable interest. The return before us is only made up to May 12th, the excessive mortality occurring in the following weeks, and to which we shall refer later on. In the present statement we are glad to learn that the rate, though high, was under that of the previous fortnight, and represents a death-rate of 31·2 per 1,000 living. Comparing the total deaths under and above 5 years, we find that last year there were 209 deaths below 5 years, as compared with 303 this—an increase of 94; while above 5 years there were 306 deaths last year, and 308 during the same period this year. The excessive mortality of the fortnight was, therefore, confined to the population below 5 years of age. 53 per cent. of the excess was directly ascribed to measles, whooping-cough, and scarlet fever. The number of deaths from pulmonary diseases was 202, in place of 223, representing a death-rate of 10 in place of 11 per 1,000 living, and constituting the same proportion of the total deaths—viz., 33 per cent. The number of deaths from fever was the same as in preceding fortnight—viz., 6, of which 5 were from enteric fever, and 1 from typhus. The number of deaths from infectious diseases of children was 105, in place of 103—viz., 65 from measles, 28 from whooping-

cough, and 12 from scarlet fever. The mortality from measles had risen still further from 51 to 65. It prevailed uniformly over the whole north side of the river with great intensity. Only 7 of the total deaths occurred on the south side. The average age of the fatal cases of measles was 23 1-10 months, and of whooping-cough 20½ months. The death-rate from measles alone was 3·3 per 1,000, and from whooping-cough 1·4, so that these two diseases added 4·7 to the death-rate. The highest weekly death-rate yet caused by measles was 3·4 in the first week of the fortnight. No cases of small-pox had been registered during the fortnight. The number of cases of fever registered was 36 in place of 24—viz., 31 of enteric fever, 4 of typhus, and 1 undefined. There were 425 cases of measles, 72 of scarlet fever, 50 of whooping-cough, and 17 of diphtheria registered, of which 68 were removed to hospital and the remainder supervised at home.

DEATHS FROM WHOOPING-COUGH IN DUNDEE.—The Dundee Sanitary Committee have had under consideration the enormous death-rate from whooping-cough during the last few months. The Medical Officer of Health reported last week that during the month of April there had been no less than 43 deaths, and that from December 1 to April 30, a period of only five months, whooping-cough had caused 225 deaths in Dundee.

Correspondence.

UNQUALIFIED ASSISTANTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—*Apròpos* of your article of the 5th inst., as one who has had some experience of the system—having myself been, before my eyes were opened as to the dishonesty and the enormity of it, both an unqualified assistant and an employer of them—I venture to offer you my opinion.

My personal experience was limited to a fortnight, after which time I threw "the situation" up in disgust, owing to the menial duties I was asked to perform; but during this short time I was sent to visit, asked to see and prescribe for patients at the surgery, and actually sent miles into the country alone to attend a woman in labour. At the time, I can confidently assert, I had never attended a midwifery lecture, studied a work on obstetrics, or seen a woman in labour. This could not have occurred had I been qualified. Fortunately for the woman, the case was over before I arrived, as I was sent on foot.

I have employed both so-called experienced (that is, aged) unqualified assistants and also mere boys. I found the former the worse of the two; they had assurance without knowledge, whereas the juveniles usually ran to me in any difficulty. The old stagers usually borrowed money, which they forgot to repay, and somehow my surgical instruments and other trifles got lost under their care.

If, as you say, freshly licensed men are in want of familiarity with the routine of general practice, so are unqualified men when they first commence their career as assistants, and they, in addition, lack the only test of competence—viz., that of examination, which the qualified men possess.

It is quite a different thing, in my opinion, to allow students to prescribe for out-patients under the supervision of some member of the hospital staff, and with the extra check of having a qualified apothecary to dispense their prescriptions, and to allow a general practitioner to employ an unqualified assistant, either for his own profit, or because he fears the superior knowledge of many of our juniors, to dub him doctor, and to pass him on his club, parish, and other ignorant patients as a doctor—all practitioners being doctors alike to some—with no check whatsoever on him either in the management of a difficult labour case, for which he loses his percentage if he send for his employer, in his prescribing, as he dispenses his own medicines, or in his treatment of surgical cases, as they are often entirely left to his own management.

I think the sooner unqualified practice, in all forms, is

made illegal the better for the dignity, profit, and honour of the profession, as well as for the welfare of the public: there are plenty of junior men available who begin with some knowledge, as proved by their having qualified, whereas the unqualified never qualify themselves; and think the first step should be, that the medical papers (*the Medical Press and Circular* is an honourable exception), and above all, that the *British Medical Journal* and *Lancet* should cease to insert their advertisements, and, secondly, that the profession should support only those medical agents who cater for qualified men alone.

The Local Government Board refuse unqualified service. The examination for the Army Medical Service is a strict one. Unqualified lawyers and solicitors are not admitted to practise, nor bogus parsons to preach; yet the lives of Her Majesty's subjects may be placed at the mercy of any ignorant quack to suit the convenience or rapacity of any unscrupulous general practitioner who is dishonest enough to pass him on his clients as

THE DOCTOR.

Medico-Parliamentary.

HOUSE OF COMMONS.—TUESDAY, MAY 22.

VACCINATION WITH CALF LYMPH.

Mr. HOPWOOD asked the President of the Local Government Board whether a memorial had been received by him from Mr. Henry Allen, of Holloway, respecting the death of his child Mabel Emma, on April 19th, 1883, alleging that she died from the effects of vaccination with calf-lymph from the the Marylebone Institution; whether, as the inquest was held without a post-mortem examination or other evidence available to prove the cause of death, he would grant the prayer of the memorialist for an official inquiry; and whether it was the fact that calf-lymph was usually followed by more inflammatory and severe effects than even human-lymph.

Sir C. DILKE: The memorial has been received, and the coroner has been communicated with, who informs me that the jury, in view of the evidence given at the inquest, gave as their verdict that the child died "from the mortal effects of pneumonia, following septicæmia from a labial abscess; and the jurors further say that the death was from natural causes." I have had before me the depositions in this case, and I have been advised that the course of the disease in this child, beginning in an altogether different part of the body from the vaccinated arm, and extending to altogether different parts of the body, while the vaccinated arm showed no undue inflammation, was not such as to suggest any connection whatever between the disease and the vaccination. The Board have accordingly replied that they have no power to review the decision of the coroner's court; and that, after fully considering the circumstances of the case, they are unable to satisfy themselves that there exists any sufficient ground for an inquiry, such as the memorialist suggests. It is a fact that calf-lymph does produce somewhat more decided constitutional symptoms than are produced by average humanised lymph.

FRIDAY, MAY 25TH.

THE CONTAGIOUS DISEASES ACTS.

Sir H. WOLFF asked the Secretary of State for the Home Department when it was intended to bring in the measures in substitution for the Contagious Diseases Acts, and the Bill for the protection of young girls.

Sir W. HARCOURT said that, in the absence of his noble friend the Secretary of State for War, he could not state when the measures in substitution for the Contagious Diseases Acts would be brought in. It was expected that the Bill for the protection of young girls would be introduced into the House of Lords next week.

MONDAY, MAY 28TH.

INDIAN MEDICAL SERVICE.

Mr. CROSS, in answer to Mr. Leamy, said the attention of the Secretary of State had been called to the exceptionally large number of junior medical officers in India drawing what was called unemployed pay. This was due partly to the unusually small number of medical officers at present absent from India on furlough, partly to the large number of young officers admitted to the service consequent on the Afghan war, and partly to the recent reduction of 22 native

regiments, with the consequent reduction of the medical staff attached to regiments. The unemployed pay of a surgeon in the Indian Medical Service was not the lowest awarded to any covenanted or commissioned officer in the Indian service. An unemployed lieutenant would draw Rs. 256 a month, while an unemployed surgeon, if under five years' service, would draw Rs. 286, or, if over five years' service, Rs. 304 a month. The present difficulty was being met by a large decrease in the number of appointments, there having been 18 for last year and 13 for this, as compared with 39 and 49 for the two preceding years. The published conditions under which officers accepted employment in the Indian Medical Service were accurately fulfilled.

THE LONDON APOTHECARIES' SOCIETY AND THE MEDICAL ACT AMENDMENT BILL.

ON Friday last a deputation from the Society of Apothecaries had an interview with Mr. Mundella, at the Privy Council Office, to urge the reinstatement of that body in the representation on the next Medical Board which is to be formed under the Medical Act Amendment Bill. Mr. Sauer, Master of the Society, and other speakers, pointed out that they had been suddenly deprived in the House of Lords of that share of representation which, in accordance with the recommendation of the Commissioners, was allotted to them in the Bill as originally introduced.—Mr. Mundella said the spirit and disposition of the Government was shown by the fact that the representation of the Ancient Society of Apothecaries was provided for in the original draft of the Bill, but in deference to Lord Salisbury's opposition the leaders on both sides agreed to omit the Society from the divisional board. It was only the House of Commons which could make any further changes, and the Bill had been sent down from the Upper House in the form in which he would have to conduct it in the House of Commons. The almost universal testimony of the medical profession was that the general provisions of the measure were excellent, and he received the statements of their Society with the utmost respect, he would give them due consideration, and he would represent their views to the Lord President before the Bill went into committee.

THE APOTHECARIES' HALL AND THE IRISH MEDICAL BOARD.

ON Wednesday, the 23rd, a numerous meeting of members of the Apothecaries' Hall was held in the board room of the Hall, at four o'clock, for the purpose of asserting the claim of the Hall to appoint a representative on the Medical Board under the Medical Act Amendment Bill. The chair was taken by Dr. Collins, Governor of the Hall.

The Chairman said the object for which they were called together was to protest against the injustice that had been done to their body by removing them from the Medical Act Amendment Bill. The Bill as originally introduced in the House of Lords by the Lord President of the Privy Council gave their body the right of appointing a representative on the Irish Medical Board. That was in accordance with a recommendation of the Royal Medical Commission; but owing to some misinformation as to the position that Hall had held as one of the medical authorities of Ireland for the last 300 or 400 years, that right was taken from them on the second reading of the Bill on the 19th of last April. Of the 2,450 medical men who were practising in Ireland, far the greater number were acting as general practitioners, compounding and prescribing as well as dispensing medicine under Poor Law and Government Boards. But what they principally laid stress on was the effect the omission would have on the future of the general practitioner. They had had a very important interview with the Chief Secretary, Mr. Trevelyan, who had assured them that the matter should receive the utmost attention from Government, and he had also promised to place him (Chairman) and Sir George Owens in communication with Mr. Mundella, the member of the Government who had charge of the Bill in the House of Commons. They had also communicated with the Apothecaries' Society of London, and had received a letter from them stating that they had been treated in the same manner, and would leave "no stone unturned" to get their proper position in the Bill. There were nearly one thousand licentiates of the Apothecaries' Hall of Ireland, and he was informed that the

English body had nine thousand on its roll of licentiates, about seven thousand of whom were practising.

Mr. Tait moved the following resolution :—

"That this meeting having considered the Medical Acts Amendment Bill at present before Parliament, are filled with consternation by the discovery that the claim of their branch of the profession is entirely ignored by the Bill, and that this act of injustice has been committed notwithstanding that their claim had been duly recognised in the first copy of the Bill introduced in the House of Lords."

Dr. Lyons, M. P., said he attended because they were his constituents, and also because he was influenced by that fellow-feeling which moved them all when professional matters were at stake. Their branch of the profession fulfilled a most important function, and the chairman, so far from exaggerating the antiquity of their body, had fallen short of it by several hundred years. That corporation dated from the arrival of Henry II. in Ireland. He was a gentleman who knew tolerably well what he was about, and after his arrival in Ireland he instituted the well-known Guild of St. Mary Magdalene, which comprised the Apothecaries' Society of that day. They were the lineal descendants of that distinguished body which occupied for a long period a position of great importance in the country. It was not until a couple of centuries later—about 1384—that the first medical degree was given by the University of Oxford. The Apothecaries' Society of London dated from 1542, so that it also was their junior. There was a great tendency at the present day on the part of the populace to run in the direction of quackery. A large body of the people of England had passed into the hands of men who were in no respect physicians, surgeons, or apothecaries. There were no less than 300 herbalists practising in England. It was most important that by unwise legislation the great body of the lower classes were not driven into the hands of unqualified men. The Apothecaries' Hall had up to the present admirably fulfilled a function which could not be performed by the other branches of the profession. He should be most happy to give the fullest effect to the views of the gentlemen present in reference to the question under discussion.

Dr. R. S. Hayes moved—

"That in enacting a State qualification for general medical practice it is of the utmost importance that the persons obtaining such qualification shall possess the requisite knowledge and skill, and that their competency shall be adequately proved and certified by a perfectly-constituted board of examiners."

Dr. Knight moved a resolution the object of which was to have a particular clause in the Bill amended so as to restrict general practitioners to the supplying of medicine to their own patients.

Sir William Carroll moved a resolution appealing for support in the present matter to the profession throughout the country.

The proceedings concluded with a vote of thanks to the Chairman.

Obituary.

DR. PETER STEWART, OF GLASGOW.

By the death of Dr. Peter Stewart, Glasgow has lost a much-respected citizen, and the medical profession of the city one who long worthily represented many of its best phases. Dr. Stewart was born in Greenock in November, 1813. His father removed subsequently to Paisley, and ultimately to Glasgow, where the subject of our notice received his early education. Dr. Stewart received his medical instruction at the University, and Royal Infirmary of Glasgow, taking his first qualification, L.R.C.S. Edin., in 1834. In 1845 he graduated M.D. (Glasgow), and in 1858 he became a F.F.P., and S.G. His studies at Glasgow were supplemented by courses at Paris and Brussels. During the earlier portion of his professional life he acted as an assistant in England, returning to Glasgow and establishing himself in practice on the south side of the city, where until within fifteen years of his death he laboured with great assiduity and faithfulness among a large and respectable *clientèle*. For the last fifteen years of

his life he resided in Albany Place, on the north side of the city, retaining, however, his early professional connection on the south side. In later years Dr. Stewart indulged a taste for foreign travel, visiting the chief cities and countries of Europe, Australia, New Zealand, and twice America, as far as California, returning on the last occasion by Panama. Dr. Stewart was a good linguist, being quite familiar with French and German, and being a good observer of men and things in addition, he travelled with much pleasure and benefit to himself. As a practitioner it may justly be said of him that he was oppressively conscientious, sparing himself neither night nor day in his devotion to his patients, by whom he was consequently held in much and deserved veneration. He kept himself constantly abreast of medical information, and was thus a constant buyer of new books and new editions, which were carefully scrutinised by him, and were no mere ornaments of his library. He had an intelligent belief in the efficacy of medicine, and prescribed both in a rational and successful manner. Dr. Stewart was too much occupied with the practical duties of his profession to contribute much to its literature. He was twice President of the Southern Medical Society, was visitor of the Faculty, and its representative on the directorate of the Royal Infirmary. When he arrived in Glasgow from California on the 1st March last he was suffering from a throat affection which turned out to be of a carcinomatous nature. He was chiefly attended by his old friend Dr. Ebenezer Watson, in whose professional skill and experience he reposed much just and intelligent confidence. During the unavoidable absence of Dr. Watson from Glasgow the operation of tracheotomy was performed on Dr. Stewart by Dr. Hector Cameron; temporary relief to the most urgent symptoms was thus obtained. The operation was performed on the 20th April, and Dr. Stewart died on the 10th May, in his seventieth year. His remains were interred at Sighthill Cemetery, Glasgow, and the funeral was largely attended by members of the medical profession and former patients and friends amidst the most unmistakable demonstrations of sympathy for bereaved friends, and respect for the deceased.

University of Aberdeen.—The following registered medical practitioners, having passed the required examinations, have received the degree of Doctor of Medicine of this University :—

Andrew, J. L., L.R.C.P. Ed.
Astles, H. E., F.R.C.P. Ed.
Brown, A., M.R.C.P. Ed.
Fisher, H. F., L.R.C.P. Ed.
Gambler, T., M.R.C.S. Eng.

Giddings, W. K., M.R.C.P. Ed.
Jameson, J., F.R.C.S. Ed.
Jay, F. F., L.R.C.P. Lond.
Kempster, W. H., L.R.C.P. Ed.
Smith, T., F.R.C.P. Lond.

King and Queen's College of Physicians in Ireland.—The following candidates, having passed the required examinations, held on May 7th, 8th, 9th, and 10th, have received the Licence to practise :—

For the Licences to practise Medicine and Midwifery.

Obarlick, A. J., Southport.
Davis, J. H., Dublin.
Dillon, P. K., Dublin.
King, R. T., Rathear.
Marsden, H. H., Birkenhead.
Farke, J. L., Tideswell.

Patterson, R. D., Moy.
Robinson, H., Liverpool.
Todd, J. J., Omagh.
Waterfield, W. H., Dublin.
Wynne, E., Dublin.

For the Licence to practise Medicine only.

Sproulle, T. W., Moville.

Walpole, G. A., Strokestown.

For the Licence to practise Midwifery only.

Fenton, A. W., M.B., B.Ch.,
Eeskey, co. Sligo.

Swan, S. A., M.D., Belfast.

Queen's College, Cork.—The following prizes and certificates for the winter session of this College have been awarded :—PRACTICE OF MEDICINE. Fourth Year: William Barter, William John Moynahan, James H. Swanton, prizes; John Bolster and John Sheedy, certificates.—MEDICAL JURISPRUDENCE: William Barter, William John Moynahan, James H. Swanton, prizes; Daniel O'Mahony and John Bolster, certificates.—PRACTICAL ANATOMY. Third Year: Benjamin Hosford, John Kearney, James F. Magner, Philip Augustine McCarthy, prizes.—ANATOMY AND PHYSIOLOGY: John Kearney, Benjamin Hosford, prizes.—SURGERY: John Kearney, Philip Augustine McCarthy, Cornelius O'Doherty, Benjamin Hosford, prizes; James F. Magner, certificate.—MIDWIFERY: Daniel O'Mahony, Benjamin Hosford, prizes; James F. Magner, certificate.—EXHIBITION IN PRACTICAL SURGERY: William Barter.—EXHIBITION IN PRACTICAL MIDWIFERY: William Barter and J. Moynahan (equal).

URIC ACID: ITS PHYSIOLOGY AND ITS RELATION TO RENAL CALCULI AND GRAVEL. (a)

By ALFRED BARING GARROD, M.D.,
F.R.C.P., F.R.S., &c.,
Consulting Physician to King's College Hospital, London.

LECTURE I.

ON being requested to deliver the Lumleian Lectures for the present year at your College, I naturally felt much gratified by the honour; but, none the less, I should have hesitated to accept the responsibility of addressing you in my present capacity, had it not so happened that I was at the time engaged in completing some investigations which I had begun many years before. As these had relation to the production of uric acid in the animal economy, and to its morbid manifestations—subjects of deep interest to the physician—I thought that the results of these researches might not be altogether without attractiveness to my professional brethren, if they were made the subject-matter of the present course of lectures.

Having, therefore, a subject to bring before you which contains some little novelty, and, as it were, breaks new ground, I put this fact forward as my excuse for appearing to-day in the capacity of your Lumleian Lecturer.

I shall not hesitate to dwell somewhat on the physiology of uric acid in my lectures, as I feel sure that any advance in its pathology which the future may show must largely depend on our having the firm foundation of a correct physiology to build upon—a thing much needed at the present time, if we may draw such a conclusion from the diversity of opinions as to the production of uric acid which are in vogue, while we have many holding that the spleen, others that the liver or the lymphatic glands, are the organs devoted to its elaboration. Nor shall I hesitate to dwell upon the condition and composition of the urinary excretion in different classes of animals, for I have long felt that, if in the study of the physiology of uric acid we confine our

attention to the human subject, we place ourselves in a position of great disadvantage towards the inquiry, seeing that uric acid and its derivatives pervade the whole animal kingdom. Furthermore, when I considered that, in some animals, the nitrogenised excretion consists almost entirely of uric acid, while in others its amount is extremely small, it occurred to me that, in the study of this principle in various classes of animals, we should be most likely to discover the true solution of its formation and the rôle which it plays in the animal economy. For these reasons I have laid great stress on the comparative physiology of uric acid in my lectures.

Let us imagine a partition separating the blood from the urinary excretion, such as, in nature, is found in the walls of the renal vessels; then uric acid, free or in combination, may exist either on the one or on the other side of this membranous partition; if on the other side—that is, in the blood—it originates symptoms which are referable to various organs; it may be deposited in the articular tissues, and produce the typical form of joint-gout, with chalk-stones; or it may affect the skin in the shape of eczema, or cause cramps, neuralgic pains, dyspepsia, &c., according to the part particularly selected. On these I shall not touch in this course of lectures having had full opportunities of setting out my views and researches elsewhere. But uric acid is also to be found on the other side of our imaginary partition; that is, in the urinary excretion, and, under certain circumstances, it forms morbid deposits, such as go by the names of gravel and calculi, and it is to these that I shall confine my attention, with special reference to their pathology and treatment.

The metabolism of the various tissues of which the animal body is composed, which occurs during life, is accompanied by the formation of certain products which require to be eliminated. Leaving out of consideration the inorganic salts, such as the phosphates and chlorides, we have certain elements, chiefly among which are carbon, hydrogen, oxygen, and nitrogen (some of which four elements enter into all organic compounds), to be got rid of. Of these, a large portion of the carbon, united with oxygen, escapes by the lungs as carbonic anhydride (carbonic acid), while the hydrogen, united with oxygen in the form of water, is thrown out by the skin, lungs, and kidneys. There remains the nitrogen—the element, *par excellence*; characteristic of life—which is eliminated almost exclusively by the kidneys, in what shape or shapes I will now describe.

(a) The Lumleian Lectures for 1883. Delivered before the Royal College of Physicians of London.

In some animals, as the mammalia, including man, urea [$\text{CO}(\text{NH}_2)_2$, or $\text{CH}_4\text{N}_2\text{O}$] is the chief nitrogenised principle, and it is the one which is richest in nitrogen, containing as much as 44.66 per cent. This organic body which was the first to be synthesised or made artificially, being very soluble both in water and in the animal fluids gives little or no trouble in its elimination, as it forms no concretions, and I am not aware that its presence in the blood produces any marked symptoms; at any rate, it can be injected into that fluid with impunity; for we must take care not to find a condition of blood showing the mere presence of urea, with the so-called uræmic poisoning.

From many observations it appears that the average quantity of urea excreted in the twenty-four hours is 512.4 grains, and that, for each avoirdupois pound, 3.33 grains are eliminated daily. It is in the form of urea, therefore, that the chief part of the nitrogen in a very large and important class of the animal kingdom is eliminated.

The next principle to be mentioned is uric acid ($\text{C}_5\text{H}_4\text{N}_4\text{O}_3$), which was formerly called lethic acid, and has recently been synthesised. This acid, combined with more or less ammonia, forms the chief part of the nitrogenised excretion of birds and reptiles, as also of almost all invertebrate animals, and a small part of that of man and the other mammalia. It contains 33.33 per cent. of nitrogen, but, if estimated as urate of ammonia, as much as 37.83 per cent. Its properties, especially as regards solubility in water or the animal fluids, differ greatly from those of urea, for it is with the greatest difficulty that it is dissolved, requiring, when pure, as much as 8,000 times its weight of distilled water at about the temperature of the blood (100 Fahr.). The salts of this acid are more soluble, but yet, in comparison with others, only slightly so, and they and the acid itself readily crystallise out from the fluids in which they are dissolved. It is owing to this property of insolubility that uric acid, although it forms so small a proportion of the urinary excretion in man, so frequently is a cause of disease. In the first place, it may congregate in the kidneys, forming gravel and renal calculi, which, when they reach the bladder, if they remain there for any time, encourage the precipitation of a further quantity of uric acid or urates upon them, and thus vesical calculi are formed; or, secondly, uric acid may be present in the blood and lead to special symptoms in different organs, or become deposited in the form of urate of sodium in various tissues, producing much discomfort.

As it is important to have a knowledge of the relative solubilities of the principal salts of uric acid, as well as of the acid itself, and as no table is known to me which shows their solubility at the temperature of the body, and as great discrepancies exist in the accounts of their solubility at any temperature, I have had a careful set of experiments made, with the results which are set out in the following table:—

Table of Solubilities of Uric Acid and its Principal Salts in Distilled Water. Temperature 100° Fahr.

		Parts	
Uric acid	Pure 1 in 8,000
Urate of ammonium (artificially prepared)	Acid urate	...	1 in 2,400
Urate of sodium	1 in 1,130
Urate of potassium	1 in 500
Urate of lithium	1 in 220
Urate of magnesium	1 in 1,600
Urate of calcium	1 in 2,800
Urate of lead	Insoluble
Urate of iron	Insoluble

There is a third body, viz., hippuric acid ($\text{C}_9\text{H}_9\text{NO}_3$), which is found in the urinary excretion; largely in that of the herbivorous mammals; in small and varying quantities in the urine of man; but is almost, if not entirely, absent from that of the carnivorous mammals. It will be seen, from its formula, that the percentage of nitrogen contained in it amounts to 7.82.

Although hippuric acid has hitherto been regarded as a comparatively insignificant ingredient, at least in the urine of man, we shall, as we advance in our subject, find that it plays an important rôle in the metabolism going on in the system, one which, to us, as students of disease, is of deep interest.

It is in the form of one or other of these three substances, with comparatively slight exceptions, that the whole of the

nitrogenised waste of the body is eliminated from the system by the renal organs, little or none escaping by any other channel.

As uric acid is the principle which will chiefly engage our attention in these lectures, and as a correct knowledge of the mode and place of its formation in the economy is of the utmost importance if we ever hope to arrive at the solution of the problem of the cause of calculi, and to develop some method of preventing their occurrence, and more especially, as the views I have arrived at during the study of the subject differ so much from those held almost by all physiologists, I shall not attempt to apologise for occupying your time with the investigation of the nature of this substance, so interesting in its physiology, and in its pathological development, leading to much suffering, danger, and even death.

Origin of Uric Acid in the Animal Economy.—There are, at least, two possible theories as to the formation of uric acid. Of these, the first is, that it is formed during the metabolism constantly going on either in the system at large, or in the special organs—such as the spleen, lymphatic glands, liver, lungs, &c.; and that, when formed, it reaches the blood, and is afterwards rapidly eliminated by the kidneys. From the point of view of this theory, the renal organs are merely the drawers-off or filterers from the blood of the uric acid which it brings to them. On looking over the principal modern books which deal with this subject, and on ascertaining the opinions held by physiologists, pathologists, and the members of the medical profession in general, I find that this view is so popular with them as to be almost universally accepted; in fact, all the attempted explanations of the influence of respiration, of the cutaneous functions, of different kinds of diet and regimen, are based upon the assumption that uric acid owes its origin to a less perfect oxidation of nitrogenised principles in the system than occurs when urea is formed, and that a meat diet powerfully favours the formation of this acid. For the sake of brevity, I shall, in these lectures, call this the *first view*.

Another, which I shall call the *second view*, may be held. In this, it is assumed that the kidney is the organ whose function it is to produce uric acid; that this principle is formed in the renal cells from nitrogenised matters brought to them by the blood; and that, in so far at least as uric acid is concerned, the kidneys do not act in any degree as filterers or strainers. There are few physiologists or pathologists, at the present time, who hold this opinion; and the discovery of uric acid in the blood, which I made in 1847, seemed at first sight, to militate against it: for it appears to follow, from the fact of the presence of uric acid in the blood, that it must be formed before the blood reaches the kidneys, and not in those organs.

In the course of our investigation into the value of these two views respectively, we shall have occasion to bring forward almost all the facts at present known with reference to the physiology of uric acid, and these require a satisfactory explanation before we can definitely arrive at any choice between the rival theories. I feel most strongly that a correct knowledge of the physiology is essential, if we hope to advance further in the pathology of uric acid.

The two theories above mentioned may be shortly summarised as follows. In the first, the kidney is regarded simply in the light of a strainer or filterer of the uric acid which is found in the blood, and passes through it. In the second, the kidney is held to be the actual producer of uric acid, and the presence of this principle in the blood and tissues is explained by resorption from the renal cells, a process which is scarcely appreciable in health, but becomes more and more marked in proportion to the difficulty which the uric acid has in finding its way to the uriniferous tubes.

In considering the physiology of uric acid, I must, in the first place, draw your attention to the fact that there are great differences between the urine of different classes of animals, both in physical condition and in chemical composition. In some animals, the urinary excretion is very thin and watery; in others, it has the consistency and appearance of thick cream, these differences depending, of course, on the ratio between the water and the solid constituents of the excretion. The constitution of the solid portion of the excretion also varies much; in some urines, the urea is abundant, the uric acid very scanty, or even altogether absent; in others, these two constituents are both present in large quantities; while, in a third class, the

urea is either very small in amount, or entirely absent; uric acid, in some form of combination, constituting almost the whole of the solid portion of the urinary excretion.

1. *Mammalia*.—The urine of man, we will not discuss at present, as we shall have to speak about it when dealing with the formation of renal calculi and gravel; it may, however be mentioned in passing that, in constitution, it closely resembles a combination of that of the carnivorous and herbivorous mammals, as, indeed, might have been anticipated from our knowledge of the anatomical structure and the nature of the food of man.

The urinary excretion of the carnivorous mammals is a watery and heavy fluid, its specific gravity being sometimes as high as 1070. I have found that of the lion and tiger to be 1063 and 1064, of a distinctly acid reaction, and a not disagreeable odour; nor is it liable, as has often been asserted, to rapid decomposition. The urine is rich in urea, so much so often that a single drop placed on a piece of glass will, after a few minutes, become a mass of crystals; and with nitric acid, it immediately becomes solid, from the formation of nitrate of urea. Uric acid is usually found in it, but in very small quantities, never, at least when the animals are kept in confinement and sparingly fed, reaching the amount contained in human urine. In that of the tiger I have found it readily, and it even crystallised out from such urine when spirit had been added to preserve it. In the lion I failed to discover it in the only specimen which I examined, but oxalate of calcium was present, a salt which was probably produced by the decomposition of uric acid.

No hippuric acid is found, at least under ordinary circumstances, in the urine of the carnivorous mammals: a fact on which I wish particularly to insist.

Next, as to the herbivorous mammals. The chief points of relation and difference between the urine of these and the carnivorous mammals may be thus summed up. It is usually a heavy fluid. I have found in the horse the weight ranging from 1025 to 1045. In the elephant (female) it was 1033; and in the camel 1047; but only one examination was made in each case. In the cow and ox I have found it as low as 1014, and as high as 1035. It is always alkaline in reaction, except in the sucking animal, and of a peculiar but not unpleasant odour; and I may here mention that my experience is opposed to the statements of many writers, for I have found very little tendency in such urine to undergo decomposition; in fact, I have placed it side by side with human urine, and found that it remained free from decomposition when the latter had become completely destroyed.

The urine of the herbivorous mammal is rich in urea, less so than that of the lion or tiger, and will not often crystallise on spontaneous evaporation, but generally becomes more or less solid on the addition of nitric acid, owing to the copious formation of nitrate of urea.

As to uric acid, such urines may be said to be free from this principle, except under peculiar circumstances; but, as these exceptions are most important from a physiological point of view, they will be referred to further on.

2. *Birds*.—The urinary excretion of birds, as far as my observations go, is semi-fluid, cream-like, and very rich in uric acid. After being expelled from the body, it soon sets, and becomes a hard white mass, in appearance not unlike plaster of Paris. As much as 90 per cent. of uric acid, or even more, has been discovered in it, together with a varying quantity of ammonia. I have always found it distinctly acid in reaction, whether the bird was living on meat or grain. Most observers have failed to find urea in the urine of herbivorous or graminivorous birds. I myself have never, as yet, been able to detect it; but in the carnivorous birds a small quantity is said to be always present, probably never exceeding a fifth part of the uric acid.

3. *Reptiles*.—In so far as the eye can discover, or as chemical analysis has succeeded in making out, the urinary excretion of ophidian and saurian reptiles is identical with, or most closely resembles, that of birds. I have carefully examined that of several pythons, boas, cobras, and the common English snake; also of various saurians, as the Australian monitor, &c. Urea is said to be absent, and with one exception—viz., the common green snake—I have failed to find it. Whether it exists, in traces, in such excreta, as a rule, is at present a moot point. In the chelonian reptiles the excretion differs from that of ophidians and saurians in that it is almost liquid,

usually consisting of a clear watery fluid containing opaque white flakes of urates.

4 and 5. *Batrachians and Fish*.—With regard to these classes of animals but little information has, as yet, been obtained.

6. *Invertebrata*.—Lastly, one word as to the nature of the urinary excretion in the invertebrates. With the exception of animals belonging to the class arachnida, as the scorpion and spider, which excrete guanine ($C_5H_7N_5O$), a substance found in guano, and probably derived from uric acid, and closely related to it in composition, all the invertebrata throw out uric acid or urate of ammonium.

Having now given a short sketch of the character and composition of the urinary excretion of the different classes which compose the animal kingdom, we are naturally confronted by the question, Why this difference in the excretion of nitrogen—why in some animals does it chiefly take the form of urea; in others, that of uric acid? The supporters of the first view have attempted many explanations, the favourite one being that it depends on the greater or less activity of the function of respiration. This, I believe, originated with Liebig, and it is a view much insisted on by chemists, for it must be remembered that the uric acid, under the influence of oxidating agents, readily breaks up into urea and other products; thus a slight oxidating cause splits it up into urea, allantoin, and oxalic acid, all of which substances are found at times in the animal economy. Liebig pointed to the fact that mammals, having a high temperature and active respiratory function, throw out but little uric acid and a large quantity of urea; whereas reptiles, with a low temperature and a correspondingly low respiration, throw out their nitrogen chiefly as uric acid. This view was at first sight most plausible, but unfortunately it was founded on limited data—it was, in fact, a most partial view, for we have only to turn to the large class of birds for its refutation. Here we see animals with the highest temperature and a respiration correspondingly active eliminating their nitrogen in exactly the same form as the cold-blooded reptiles.

Lastly, we may look at the excretion of invertebrate animals, whose temperature is high, while no urea is found in their nitrogenised excreta.

The nature of the food taken has been thought by many to have a powerful influence on the excretion of uric acid, but it needs very little consideration to show the inaccuracy of this idea; for ophidian reptiles, as the python and boa, which live exclusively on animal food; and grain-eating birds, such as the canary and others, whose food consists entirely of seeds, excrete the same nitrogenised products—in fact, it is difficult to separate the urinary excretion of the one class from that of the other, as I have already stated, both consisting of uric acid in combination with some ammoniacal compound. Again, if we compare a toad with a lizard, the little influence of the character of the food is at once strikingly shown. Both animals live on flies, yet the urine of the toad is clear and watery, and contains no appreciable uric acid; whereas that of the lizard resembles cream, and consists mainly of urate of ammonium. The excretion of uric acid, and of urea also, is doubtless much influenced by the amount of food taken, whether in the same ratio has not yet been determined.

Some physiologists look upon the spleen as the producer of uric acid; others regard, some the liver, some the lymphatic glands, and some the cartilaginous tissues as the originators of this principle; but there is one fact which must not be lost sight of—viz., that whether an animal throws out all its nitrogen in the form of uric acid or in that of urea, it equally in either case possesses a spleen, a liver, lymphatic glands, and cartilaginous tissues.

Of course, if we accept the second theory, and regard the kidneys as the producers of uric acid, the difficulty of the question is at once solved. We have only to regard the kidney as containing different cells—some, perhaps, for the formation of urea; some, at least, for the production of uric acid, and to hold that the number of the latter cells, compared with the other excreting cells of the kidney, differs in different classes of animals. The amount of respiration in any animal would then be of little moment with reference to the excretion of uric acid; also the nature of the food, provided only that the blood contained sufficient pabulum fitted for its supply. Possibly, however, many of us already see difficulties ahead, which have to be resolved before such a view can win acceptance.

(To be continued.)

REMARKS ON THE USE OF THE MOXA IN
CHRONIC AFFECTIONS OF THE SPINAL
CORD. (a)

By D. H. CULLIMORE, M.D., M.K.Q.C.P., &c.,
Senior Physician to the North-West London Hospital; formerly
Medical Staff, Indian Army.

MR. PRESIDENT AND GENTLEMEN,—In the remarks which I am about to offer my principal aim is to endeavour to show the advantages that attend the use of the moxa in sclerosis and other chronic inflammatory conditions of the spinal cord and the intractable and often incurable diseases depending thereon.

With this object I shall first detail a few cases where this method was tried with the best results, and then briefly draw attention to the history of the moxa, its mode of application, and the great value which, as it appears to me, it possesses over other forms of counter-irritation in the diseases in question.

The first case is one of infantile paralysis occurring in a girl, *æt.* 11, who was admitted into the North-West London Hospital, Nov. 6th, 1880. She gave the following history, which was confirmed by a very intelligent sister:—

Having been a delicate child from her birth, she was, when two years old, unable to sit up, owing apparently to weakness of the lower part of the back, together with some deformity of the feet and knees, for the relief of which she went to hospital and had the tendons divided. This treatment appeared to be ineffectual, her limbs falling in and continuing to give way whenever she attempted to stand. After a year she was taken to another hospital, where she was treated for rickets, and again, at the age of 8, to a third institution, where electricity was applied, and there being spastic contraction of the muscles, the tendons about the knee and ankle-joints were divided with some advantage, and an iron supporting apparatus supplied, which she wore till coming under my notice. But as at this time it was a weight instead of a support, and appeared to interfere with the circulation in the lower limbs, which, though not greatly emaciated, were of a bluish, erysipelatous hue, and presented a cold and statue-like feeling to the touch, I had it removed.

When examined, she was helpless as regards the use of the lower extremities (particularly the left), being unable not only to stand, but to move one foot over the other in bed. Sensation was also slightly impaired. The patellar tendon reflex and galvanic contractility were absent. There was also awkwardness and slowness in the movements of the upper extremities, together with thickness and slowness of speech. Pressure over the vertebræ was not attended with pain. The temperature and heart's sounds were normal. Pulse 120, respiration 20.

The treatment consisted in remaining quietly in bed, with the application of a moxa twice a week, which was continued for three months, with the following mixture:—

R. Tr. belladonnæ, ℥iv.;
Tr. nux vom., ℥ij.;
Aquæ ad ʒij.

M. To be taken twice a day.

This medicine was continued from the 8th of November till the 1st of January, 1881.

Jan. 1st.—After a few weeks she was well able to move her legs in bed, and after six weeks to get up and walk a little with assistance. At this period 1-20th of a grain of phosphide of zinc was substituted for the mixture above noted.

March 1st.—Can now walk alone, but with the gait of an old and feeble person.

July 1st.—The improvement continued till the end of June to such an extent that she was able to walk to

church; but at this time, owing to an unfortunate fall on the stairs, her further progress was retarded, and she left at Christmas in good health, being well able to walk across the ward slowly without assistance.

April 1st, 1882.—Again admitted in a weak, emaciated, and deteriorated state, owing to the combined effects of falls, insufficient food, defective clothing, and mental annoyance, pointing to the danger of sending such patients from the comfortable and warm wards of an hospital to the coldness and hardship of a poor home and unsympathising, because wearied, care of relations.

Owing to the hopelessness of improvement within a reasonable period, she soon left, and of her present condition I am not aware.

The second case is one of chronic myelitis the result of injury, and occurred in a boy, *æt.* 12, who was admitted under my care June 1st, 1880.

In August, 1879, he fell and injured his back, as a result of which symptoms of paraplegia, not suddenly, but slowly, developed themselves, pointing to the absence either of fracture or dislocation of the vertebræ, of effusion of blood, or acute inflammation.

He was treated like the last patient, in three institutions. First a spinal jacket was applied, and there being obstinate constipation, strong purgatives, with strychnia and belladonna, were given. In the second, where he was admitted on the 3rd of January, 1880, the treatment I have not found out. It was, however, so far from being effectual, that coming under homœopathic influence, he sought relief in a homœopathic hospital, whence, he states, after a trial of a few months, he was discharged incurable.

When I saw him on the 1st of June there was complete paralysis of motion of the upper as well as the lower extremities to such an extent that he was unable to move in bed or to feed himself, with impairment of sensation. There was also extreme emaciation, obstinate constipation, bed-sores, and incontinence of urine, showing an extent and depth of the lesions in the cord in marked contrast to the first case, where the degeneration was probably limited to the grey matter in the anterior cornua and the nuclei of the motor roots and their nerves. There was no paralysis of the cranial nerves or centres.

Treatment.

The moxa was applied twice a week, 30 grams of compound jalap powder, with a drop of croton oil occasionally, and the following mixture:—

R. Tinct. belladonnæ, ℥iv.;
Tr. nux vomica, ℥ij.;
Tr. ferri mur., ℥iv.;
Aquæ ad ʒij.

Ter in die.

This mixture he took while in hospital.

For a month after admission the symptoms, with the exceptions of the bed-sores, and those referable to the bladder, continued unchanged. About this time he slowly learned to move his legs and to assist in feeding himself. On the 1st of September, three months after admission, he commenced to walk with the aid of a chair, when, contemporaneously his bowels were opened spontaneously for the first time, and in a few days, having felt the use of his feet, he was able to walk without assistance.

He was discharged cured, having greatly regained strength and plumpness on the 30th of September, just four months after, and is now, I hear, earning his bread in some situation.

Three other cases I will briefly allude to. One was a case of old-standing hemiplegia with descending sclerosis; it occurred many years ago, in India, and the patient, an old man, was much benefited by the moxa. The third was a case of chronic myelitis due to injury, causing paraplegia, involuntary passage of urine and feces, and loss of reflex muscular contractility. For a month small doses of belladonna were tried without effect, but almost contemporaneously with the use of the moxa improvement com-

(a) Read before the Medical Society of London, 9th April, 1883

menced, and continued to such an extent that after a few weeks the child was able, not only to move its legs, but make an attempt to stand. It unfortunately caught whooping-cough, and had to leave. The fifth and last case occurred in a child two years old. The disease came on insidiously, is confined to one leg, which, on admission, Feb. 4th, 1883, was shrunken and paralysed, with loss of reflex contractility. This patient is also having the moxa, and is now, without any other medicine, able, not only to stand, but to walk a little as well.

These cases, I may safely state, practically illustrate the value of the moxa, though I do not forget that it is open to say that something is due to the belladonna, nuxvomica, &c., contemporaneously administered.

But when we remember the chronic character of the disease, and the undoubted expenditure of the *vis medicatrix nature*, and the certainty in the first and third cases, and the probability in the second, that these or similar drugs had a fair trial and failed, it is impossible not to be convinced that the complete cure in one case, the great improvement in two cases, and the expected cure in the fourth case is due to the moxa.

I might conclude here, were I not anxious to show that the use of the moxa, which is undeservedly neglected, and which is not even mentioned by most of our popular therapeutic writers, can be supported as strongly by theory and argument as it has been just illustrated by practice.

It may, I think, be granted that counter-irritation in some form is frequently advantageous in the degenerations and chronic morbid states under review.

But it may nevertheless be useful to pause and ask ourselves what is the *rationale* of its curative power. In fact, for my purpose of showing the superiority of the moxa to other forms, it is necessary to do so.

Counter-irritation, broadly speaking, is of two kinds. The first may be likened in its effects to a kind of local depletion, as when a large fly blister is applied for a considerable duration of time, as in the early stage of acute inflammation, for example, over the lungs in pneumonia. The serum of the blood is withdrawn, and the subjacent congestion relieved. The second is similar in its action to the stimulating effects of strychnia and electricity, and is adapted to chronic morbid conditions, in the anæmic states of the system, and for the dissipation of old fluid collections. Its action may be illustrated by the use of firing in joint disease, and that of the moxa in the diseases in question. In both kinds the stimulant influence is exercised primarily through the nervous system, acting secondarily on the vessels of the part morbidly affected. Thus in the very early stage of acute inflammation we can easily understand the depleting effect of a good blister, the vessels still retaining some functional power.

The following experiment of Nauman will illustrate the reflex stimulant action of the second form of counter-irritation when applied to sclerosis of the cord. The head of frog was removed the medulla intact, and its mesentery exposed, and one thigh, after ligation of the blood-vessels, was separated from the body, leaving only the sciatic nerve unimpaired. On applying a mild galvanic stimulus to the web of the prepared extremity, and examining the vessels of the mesentery, the current in the vessels was observed to be quickened, and rendered continuous instead of wavy. A through current caused the vessels to separate from each other, and to appear more distinct. At the conclusion of the experiment the blood current assumed its *original rate*. In this way the vaso-dilator nerves are at first stimulated, and then, becoming tired, resume their normal state of quiescence, showing that, whatever form of counter-irritation is used, it must be reapplied at intervals. This experiment explains not only the action of electricity—an agent of the greatest utility in chronic spinal affections—but which sometimes, as in some of the present cases, failed (I may here state that I did not try electricity, as I wished to give the moxa a fair trial, but it was tried before by others); but it has a wider significance, explanatory of all cutaneous irritation on the circulation

through the action of the nervous system by a reflex operation.

If the stimulating action of electricity is similar to that of the moxa and some other forms of counter-irritation, in what, then, it may fairly be asked, does the superiority of the moxa consist? Having noticed the advantage of the moxa where electricity had failed, owing probably to the impairment of the receptivity of the nerve fibres or centres allotted to the conduction and presidence of electrical force, as shown by the want of electrical contractility, it appears to me not unreasonable to contend (and the slight and often non-impairment of common sensation confirms this view) that the centres and fibres associated with common sensation and the sensation of *heat and cold often remain intact*, while those connected with electricity are, in chronic cases, usually diseased. Even in loco-motor stax the often normal condition of the *superficial reflex excitability* is remarkable when we remember the total absence of the patella and other tendon reflexes. In this disease, also, the sensibility to heat and cold, &c., usually remains to the last. These things, at any rate, show the rarity of nerve fibres, and that consequently a therapeutic agent, whose ultimate result is the same, may differ greatly in power, owing to the freedom or blockage of the channels along which it is distributed. Thus far I have tried to explain the theory of the stimulating action of cutaneous irritation in general. I will now discuss the special advantages of the moxa, first saying a few words descriptive of this agent, including its history.

History and Description of the Moxa.

The physicians of Greece and Rome, who all used some form of counter-irritation, were not, as far as I can find out, familiar with the moxa, which would appear to be of Eastern origin. It was introduced into the West by the Portuguese soon after their earlier Eastern conquests, whether from India or China is not clear, though I may say that when in India I was informed by an intelligent Portuguese. Eurasian that it was first carried to Europe by the physician of Albuquerque, the conqueror of India. The great surgeon Larrey became aware of its value during his Egyptian campaigns, and spoke highly of its utility; but in all the works on materia medica which I have referred to, except that of Stillé, who gives a good account of it, the moxa finds no place. Even the homeopaths, so prolific on the treatment of disease, have forgotten to make it conform to their great axiom.

The moxa may be made of many substances, such as the down of the various species of the artemesia, the agaric of the oak, flax or hemp impregnated with inflammable matter, or linen saturated with nitrate of potash. Larrey's moxa was an inch long and half-an-inch broad. This I consider too short, as its action would be too rapid and severe, and of the other forms above alluded to I have no experience. That which I myself use consists of a piece of brown paper about 15 inches long and 4 broad. This is saturated in a solution of nitrate of potash in proportion of ʒj. to ʒj. of water. A stronger solution, or one of chlorate of potash, is not advisable, as it is liable to burn with a flame, which should be avoided. This paper is dried and rolled into a cylinder, and is then ready for application. It resembles a short cigar without the tapering ends. To apply it, one end is set on fire and the other placed on the skin in the vicinity of the subjacent disease. The neighbouring parts should be protected with alum paper with a central hole, while the degree of heat can be moderated to any degree by the moxa holder or forceps, and freshened if necessary by blowing upon it. I always remove it before the burning part comes in immediate contact with the skin. In this way no scar or sore is ever produced, and it can be reapplied as often as necessary.

During its application the first degree of heat is attended with an agreeable sensation, which gradually increases, but is rarely severe, and has never been much objected to by my patients, who, on the contrary, seem rather pleased at the idea of the application, as the pene-

trating heat makes them feel comfortable for some time after. In fact, of all such applications it is at once the mildest and, I believe, the most efficacious, at all events, in certain conditions which experience will teach us to recognise. It is as well, however, not to apply it where the skin is the only covering over bone, tendon, or cartilage.

The substitutes for the moxa are the actual cautery, Major's hammer, blisters, and the various medicinal applications with counter-irritant properties.

The actual cautery, though sometimes a useful remedy, is so formidable that the physician as well as the patient are reluctant to have recourse to it.

Besides, as the experiment I have quoted shows, a frequent repetition of the stimulant is necessary to produce an increased circulation in the vessels of the affected part, and this can hardly be done with the cautery without causing bed-sores in patients particularly liable to their formation. Major's hammer is equally severe, for when dipped in water at a temperature of 170° or 150° Fahr. it not only causes acute pain, but produces an eschar as well.

To blisters there is the same objection, with the additional one that the absorption of the cantharides, the croton oil, &c., may prove injurious, and will certainly complicate the interpretation of the value of the remedy. Moreover, the moxa, in addition to the counter-irritant action common to it and other forms of counter-irritation (and be it remembered that in suitable cases its beneficial effect is greater where it falls short of any local inflammation or desquamation of the skin) has, I believe, other curative powers which they do not possess, due to the heat which, when it is made as I have directed, is slowly evolved, and, accumulating in the centre of the cylinder, penetrates in a concentrated form to the deeper parts. It is not, however, in the cases alluded to that the moxa is alone advantageous. In locomotor ataxy I should like to see it tried, and tried persistently, for persistent application is necessary, and great patience, and often personal attention, is required. In all forms of sclerosis it may do good, and can do no harm, also in descending hemiplegia. In *clonus hysterics* I have seen it effect a cure, though I have also seen it fail to do so. In *sciatica*, *rheumatism*, and painful affections of the fascia, in fact, wherever vascular stimulation may be required or considered desirable, we should not forget the moxa, which, to repay us our attention, must be treated with caution, care, and with perseverance, and with perseverance above all.

Clinical Records.

CASES IN PRIVATE PRACTICE.

Case of Migratory Gout.

Under the care of Dr. MYRTLE,
Consulting Physician to the Harrogate Bath Hospital.

(We are indebted to Mr. JAS. A. MYRTLE, M.B., C.M.,
for the Report.)

THE following is the record of an interesting and singular case of migratory gout which occurred last summer in my father's practice:—

Mr. M. A., *æt.* 55, of sanguine habit, suffering from psoriasis, slipped when getting out of his bath, on September 22nd, and sprained his knee. He treated this as the late Professor Syme had done after a similar accident. On the 1st of October my father saw him. The knee was red and much swollen, very painful on slight movement; there was no rise in temperature, but the patient complained of loss of appetite, acidity, flatulency, and general depression.

Diagnosis.—Acute attack of gout. The knee was ordered to be wrapped in cotton-wool and kept at perfect rest, no medicine, and simple diet.

On the following day (the 2nd October) the patient was just the same.

On the 3rd, the pain and swelling had disappeared from the knee-joint, and he now complained of severe

pain over the *caput cæcum*, increased by pressure, coughing, or straining; no hardness or lump was to be felt, but the pain was such that he could hardly bear the bed-clothes touching him. Hot applications, with mustard locally, morphia and atropia hypodermically, gave almost immediate relief. During the afternoon he was attacked with severe diarrhœa, which continued, in spite of the usual remedies, for eighteen hours. On its cessation he was seized with dyspnoea, accompanied by a severe and constant cough and the expectoration of a clear,ropy mucus. This lasted all night.

The morning of the 5th found the patient very exhausted, pulse feeble, 60, temperature 97·2°, still complaining of the pain in the abdomen, urine scanty, loaded, and the bowels confined. On examining the chest there were no physical signs of mischief to account for the cough and expectoration. During that day the chest symptoms left him.

On the following morning (the 6th) he complained of severe pain over the kidneys, the urine was scanty, faintly tinged with blood: in the evening it looked exactly like blood. During the night the pain left the kidneys and attacked the liver, which next morning (the 7th) felt full and tender; on slight pressure the urine, instead of being bloody, was found highly charged with bile. The bowels were still confined. On the 8th the constipation was as obstinate as ever; the abdomen was becoming tympanitic and tender. On the 9th the tympanitis and pain had increased so much that the patient could not bear the weight of the bed-clothes. On the 10th the heart and lungs showed symptoms of pressure to an alarming extent. He looked pinched and sinking, nothing remained with him, and the vomit became slightly feculent. Large stimulating enemata had failed, and nothing but small pieces of ice were given by the mouth, and morphia and atropia hypodermically.

On the 11th he was, if possible, worse, the heart being most seriously interfered with; a low muttering delirium had set in, and the patient appeared to be in a dying state. Mustard poultices were applied to the joints and limbs, and a large enema of egg emulsion, with one ounce of turpentine, was administered. This was retained for more than an hour, when it came away, and with it some hard masses of stiff, clay-looking *fecæ*; these were quickly followed by copious loose, bilious, offensive motions, and large quantities of flatus. After this all the grave symptoms speedily passed off, and the patient made steady progress in convalescence, one of the things which seemed to assist him most being a return of acute gout to the balls of both great toes. During his illness the psoriasis became fainter and fainter, but as soon as he began to gain strength it returned to its favourite seats. Throughout there was a decided tendency to faintness; the pulse and temperature were below, never above, the normal, showing that the sympathetic nerve centres were materially interfered with by the presence of the gouty poison. Mr. M. A. was not aware that any member of his family had ever suffered from gout, and had led an active and temperate life.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

THE CONTAGIOUS DISEASE ACT.—The recent vote in the House of Commons on the Contagious Disease Act has been a signal triumph for the Abolitionists; and Mrs. Butler, who no doubt was moved by the noblest sentiments towards her sex, must congratulate herself on the victory obtained. Yet I think that if the Medical Society were asked to give their opinion the result would have been far different. In any case, it must be confessed that the compulsory examination of women is becoming repugnant to the minds of many on the Continent. The Municipal

Council of Paris has lately addressed a letter to the Prefet, demanding the immediate confiscation of the Louraine and Midi Hospitals, and the abolition of all the *maisons de tolérance* in the city and the Department. More recently they have voted the suppression of compulsory examination and treatment of women, and the abolition of the *police des mœurs* is under discussion. In Germany and Italy the question is receiving serious attention from the respective Governments. The Countess de Précorbin, who is the leader of the abolition movement on the Continent, has favoured me with an account of the campaign she has led throughout the whole of Europe; and amongst the many members of the Federation which she has been able to enlist, I remarked the names of several eminent medical men.

PRODUCTION OF CHARBON.—The works of Davaine and Pasteur have established in an incontestable manner that in man charbon is produced by the penetration of a bacterium through an effraction of the epiderm. M. Richet, of the Hotel Dieu, has had recently two cases which have thrown some light on the facts which have been, up to the present, rather obscure, of the double evolution, proliferation on the spot, and afterwards general infection. These cases, besides, offer a certain importance as regards the treatment by injection of iodine. In the first case, the liquid taken from the pustule and inoculated into animals communicated immediately the infection, and in spite of injections of iodine, the animals succumbed. In the second case, eight injections of the tincture of iodine, mixed with two-thirds of water, was made around the tumour; and the patient, who had been in an alarming state, immediately improved, and finally got well. M. Richet recommends that from one to two drachms of the tincture of iodine, mixed with two volumes of water, should be injected in a circle around the pustule, and repeated several times a day during several days, whether the disease advances or recedes.

ON RESECTION OF THE LUNG.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to a note from your French correspondent in your last issue, May 30th, on "Resection, &c., of Lung by Thermo-Cautery," in which this operation is attributed to Dr. R. Koch, of bacillus tuberculous celebrity, I beg to refer him to p. 572, vol. ii., 1882, *Medical Press and Circular*, in which the following passage occurs:—"W. Koch (who must not be confounded with Dr. R. Koch), a surgeon of Dorpat . . . applied the thermo-cautery, plunging it into the lung tissue." Your correspondent has been doing what I expressly warned your readers against—viz., confounding W. Koch, of Dorpat, a surgeon, with R. Koch, of Berlin, a physician and scientific investigator, at present in the Prussian Government Service.

I am, yours, &c.,

THE WRITER OF THE SUMMARY.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their populations, were—Birkenhead 12; Norwich 15; Plymouth, Cardiff, Wolverhampton 16; Portsmouth, Brighton, Bristol 17; Bradford, Bolton, Leeds 18; Huddersfield, Nottingham 19; London 20; Edinburgh, Birmingham, Hull, Derby, Blackburn, Preston, Oldham 21; Sheffield, 24; Sunderland, Liverpool, Leicester 25; Halifax, Salford 26; Dublin 27; Newcastle-on-Tyne 30; Glasgow 32; Manchester 33.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MAY 25TH.

The President, ANDREW CLARK, M.D., LL.D., in the Chair.

Dr. ROBERT LEE on

CASES OF NYSTAGMUS INFANTILIS.

The first case was one of instrumental delivery with consequent asymmetry of the cranium; atrophy of the right hemisphere; ventricular effusion, and other changes of the right side of the brain. The chief symptoms were frequent attacks of excitement and active movements of the head and body of a few minutes duration; also nystagmus with left internal strabismus. The question discussed was the value of nystagmus as a measure of central lesion, and its help in prognosis. Other cases were mentioned where nystagmus had followed convulsions, falls on the head, or were traced to maternal influences preceding birth.

Dr. ANGEL MONEY explained that a microscopical examination of the brain had not yet been made. He had found no signs of sclerosis in the postero-lateral columns of the cord, and there was no obvious change of any kind in the cervical region. The sensory ganglia of the brain were atrophied, probably through hæmorrhage induced by instrumental delivery.

Dr. B. ROTH had observed nystagmus in an Albino seven months old, and considered the effect might be due to avoidance of light in such cases. He wished to hear if it was thought probable that the condition under discussion would disappear as the subjects of it advanced in age, and also whether it was regarded as being present in all Albinos.

Dr. LEE thought nystagmus was unduly neglected as a symptom by physicians, and that evidence of its intra-ocular origin was not forthcoming in amount to justify refusal to accept the theory of its central origin. It was difficult to submit children to ophthalmoscopic examination, notwithstanding such examination may be the only mode of arriving at safe diagnosis. Dr. Lee related the case of a child, æt. 3, under his care, in which nystagmus was for a time the only sign of disturbance present. The condition varied during the succeeding twelve months, health occasionally improving also, but death took place in the fourth year. He did not think the explanation of effusion into the ventricles sufficient, and urged the need of more attentive study of nystagmus.

Dr. ANDREW CLARK corrected the impression conveyed by Dr. Lee's remarks, to the effect that ophthalmic surgeons insisted on intra-ocular changes as being the efficient cause of nystagmus. Dr. Clark explained that some cases of the disease were found to be due to such disturbance, but in others there were unquestioned cerebral changes of a definite kind involved, and no ophthalmist would think of denying their occurrence.

Mr. BARKER on a case of

EXCISION OF SMALL GOITRE—RECOVERY.

The case brought forward is one in which a small goitre produced great difficulty of breathing on exertion. Excision of the tumour was required, and this operation was followed by complete relief. The patient was a woman, æt. 21, who had noticed a swelling in her neck first when fourteen years old. Two years later she began to suffer from difficulty of breathing. Three years ago she was under treatment for a considerable time at a special "throat hospital." This treatment consisted, in the first place, of simple puncture of the tumour, with evacuation of about half-an-ounce of brown fluid. Then leeches were applied. Thirdly, injections of tr. iodi. were tried at intervals for three months. Fourthly, a seton was passed through the tumour, and left *in situ* fourteen days. It had to be removed on account of constant vomiting. After this, she was treated by "electricity" at another hospital. Ever since, the tumour had increased. It measured, at time of operation, three inches in transverse diameter, and two in the vertical, and reached to the top of the sternum. It was firm and elastic, but not fluctuating; was movable and marked by dilated veins. It moved upwards with the larynx in the act of swallowing, and slight pressure upon it produced considerable distress of breathing. The patient was unable

to follow her calling as domestic servant, on account of the difficulty in breathing, which was greatly aggravated on exertion, and became—by her own account—paroxysmal at times. There was no exophthalmos. As all the ordinary means of relieving the condition had failed, Mr. Barker removed the tumour on August the 24th, 1881. This was done with all Listerian precautions as to aseptioity. A median incision, about four inches long, gave access to the tumour, which was cautiously dissected out as much as possible with blunt instruments. It proved to be the enlarged right lobe of the thyroid body, the left lobe and isthmus being normal. The latter was ligatured and divided, and the left lobe was not removed. During the dissection the vessels were tied with double ligatures, and divided between the latter. In this way seventeen silk and six catgut ligatures were used and left in the wound. Hardly any blood was lost, and the important structures around were not interfered with in the dissection. A drainage tube and gauze packing completed the operation. The next morning all the dressings were found to have slipped and become loose during the night, and salicylic wool was substituted without the spray. The wound healed almost entirely by first intention and without any inflammatory reaction, and the patient left the hospital well on September 14th. On her return from the country she was found to be quite relieved of her former trouble. The patient has been under constant observation now for nearly two years, and has had none of her former distress though she has returned to service. She has had some neuralgia in the neighbourhood of the wound at one spot which is also a little tender to the touch. Not one of the ligatures left in the wound has ever come away or shown signs of its presence, unless the neuralgia alluded to be taken as such. As the patient suffers from amenorrhœa, however, neuralgia might well be due to other causes. The author suggests the importance of collecting evidence as to the behaviour of aseptic silk in wounds of parts easily accessible to examination, seeing that as regards security and uniformity of texture most surgeons would prefer it to catgut; and if it be shown to be tolerated by the tissues as well as the latter the choice of ligatures would be simplified. This case offers in this direction several points for reflection. The author further points out that this is one of those cases which are probably far less uncommon than is supposed where small bronchoceles have produced very serious symptoms. He draws attention to other cases recorded or referred to where small tumours of the kind have produced fatal attacks of dyspnoea, and he concludes by suggesting much earlier operation for such bronchoceles than has hitherto been customary.

Mr. SYDNEY JONES described a mode of operation in these cases adopted by himself with much success, in imitation of Continental surgeons. The operation consisted in the removal simply of the isthmus of the thyroid body, ligatures being first applied on each side. In the case of a boy treated in this manner, and in which, from approximation of the mass of the trachea, introduction of a tube would have been very difficult, a complete and speedy cure was obtained, the most remarkable sequel to the operation being the atrophy of the lobes of the thyroid which followed it. Mr. Jones strongly advised that recourse should be had to this operation rather than to one involving such an amount of risk as that of removing the whole gland.

Mr. HOWARD MARSH related the history of a distressing case recently admitted into St. Bartholomew's Hospital. The patient, a man, æt. 21, was suffering from extreme dyspnoea, which was induced by the enlarged thyroid. Tracheotomy about the level of the isthmus was done, the trachea being found flattened antero-posteriorly, and lending difficulty to insertion of the tube. Relief was obtained by the means adopted, and subsequent operation for removal was contemplated. An attack of dyspnoea, however, carried off the patient in the night. Mr. Marsh approved the plan suggested by Mr. Sydney Jones, and thought that Mr. Barker's case would tend to convince surgeons of the necessity for immediate radical measures in these cases to relieve the dyspnoea. Respecting the silk ligature, he could add from his own experience of ligaturing the subclavian artery with that substance that most of it was retained without inconvenience. Mr. Lister was in the habit of leaving even the thick silver wires with which he sutured fractured patellæ, and with no ill consequence.

Mr. PEARCE GOULD remarked on the superiority of the operation recommended by Mr. Sydney Smith as compared

with extirpation, on account of the support given by the gland substance left behind, and thus preventing the forward dropping of the head which sometimes occurs in these cases from softening of the trachea. He asked whether such condition of the tube existed in Mr. Barker's patient; a small goitre did not usually set up such an amount of dyspnoea. Mr. Gould's experience of silk as a ligature confirmed the previous observations made on the subject.

Mr. PARKER referred to a case in which he had assisted to remove the whole thyroid gland from a child without any relief being thereby afforded to the patient. He had also under observation four women with laterally enlarged thyroids. He suggested that dyspnoea in these cases might sometimes be due less to pressure than to the mere presence of the tumour, or to interference with the inferior laryngeal nerve.

Mr. HAWARD observed that dyspnoea was usually associated with small bronchoceles, and that it ought, therefore, to be ascribed to the nature and position of the tumour. Small goitres were usually fibrous in character, and pressed tightly on the trachea and laryngeal nerves. Mr. Haward's experience led him to think dyspnoea was not often associated with lateral pressure, and in such cases the operation recommended by Mr. Jones would give relief.

Dr. LEE referred to the probable differences existing between thyroid enlargements in cretins, and in, e.g., a girl of 15 or 16. Pathological differences were of great importance. He described a case in which at his recommendation a goitre treated for three or four years in vain and in various ways was reduced by repeated hot fomentations; whereas he concluded it was unscientific to treat all cases of bronchocele on the same plan.

Mr. BARKER agreed that pressure was not essential to the production of dyspnoea, and was glad to be supported in the opinion that such condition of breathing was commonly associated with small tumours. He had found improvement follow employment of iodine internally and externally. In the case he had recorded, successive attempts at treatment were made altogether in vain: only one lobe of the gland was enlarged, and it alone was removed. The trachea was unaltered; but before the operation Dr. Poore had noticed a backward pressure on its anterior wall. The incision was purely median, and permitted the enlarged lobe to be readily shelled out. While fully agreeing with Mr. Jones that a mild form of operation was much to be preferred, he thought a much larger number of cases of the new operation must be observed before its real merits could be gauged. In his own case the structure of the growth was essentially fibrous.

Dr. HABERSHON on a case of

ULCERATION AT THE PYLORUS, SITUATED AT THE VALVE, THE FLOOR OF THE ULCER BEING FORMED BY THE NECK OF THE GALL BLADDER.

It occurred in a gentleman, æt. 60, who began to suffer about nine months before death from pain at the stomach and vomiting; the pain was very severe in character, but most irregular in its onset, and the point of great clinical interest in the case was that "at no time during his illness did food aggravate the pain." The words were quoted from a letter of his medical attendant, Dr. Archibald. There were considerable intervals of relief, and after some weeks of comparative comfort, he was suddenly seized, after taking luncheon with his family, with intense pain in the abdomen, followed by collapse and death in about fourteen hours. The ulcer had extended through the coats into the peritoneum, and thus extravasation of the gastric contents caused fatal peritonitis. The absence of one of the most prominent symptoms of gastric ulcer—viz., pain produced by food, was remarkable. It was stated that the pain of gastric ulcer ceases from varied causes, such as the healing of the ulcer, the relief of congestion from hæmorrhage, the division of the nerve from sloughing, or from the position of the patient. In the case narrated there was no evidence of hæmorrhage, nor was there any destruction of the nerve connection. The ulcer was situated at the pylorus itself, and it was doubtful at first whether it was on the duodenal or the gastric side of the valve. It was divided into two parts by a central contraction as if there had been a healing process, or as if the ulcer had been double. The base of the ulcer was formed by the neck of the gall bladder, and it was at this part that perforation had taken place. The walls of the stomach were not thickened, as if there had been pyloric obstruction. It was suggested that the situation of the ulcer had to do

with the absence of pain, and that when food was taken the pylorus contracted and the pain ceased.

Dr. MAHOMED inquired whether a symptom observed by himself in the subjects of gastric ulcer, and consisting of a ball rising up in the epigastrium, had been noticed by Dr. Habershon.

Dr. DRUITT suggested that gastric ulcers were of frequent occurrence, but were undiagnosed among hospital patients.

Dr. HADDEN asked whether the relief to pain experienced by Dr. Habershon's patient might not have been due to separation of the ulcerated surfaces following ingestion of food?

Dr. MONEY thought the ulcer might be due to lesion of trophic nerves.

Dr. HABERSHON had frequently recognised the ball phenomenon mentioned by Dr. Mahomed, and attributed it to its proper cause—flatulency. In the particular case recorded, however, it had been absent. He was inclined to ascribe the greater number of gastric cases to nervous disturbance rather than to ulcerative changes. He thought Dr. Hadden's suggestion a very probable explanation of the facts, and had intended to imply such a theory of causation in his paper.

THE UNQUALIFIED ASSISTANT SYSTEM

AND THE

ILLEGAL SIGNING OF DEATH CERTIFICATES.

(Continued from page 468.)

THE RISE AND PROGRESS OF THE SYSTEM OF EMPLOYING ASSISTANTS.—(Continued.)

MR. GRAHAM, coroner in the County of Durham, in a letter, says: "I have felt considerable surprise at this state of things having been allowed to exist so long as it has without any action being taken in the interest of properly qualified medical men."

The employment of uncultured persons as assistants is unfair to those who are subjected to the companionship of this class of colleagues. It prevents their getting into more congenial society, and has been known in some instances to lead to the adoption of low and immoral habits. Our correspondents who have been unqualified assistants in early life invariably speak of it as their "misfortune." Several of the large employers of assistants state that the majority of young men they have had under them have been "emphatically gentlemen;" and to offer grocers' or druggists' shopmen as colleagues to such worthy representatives of the profession is a gross abuse of influence and opportunity.

It is this latter class of unqualified assistants who (as may be learnt from advertisements) "would live in the kitchen or outdoors at a nominal salary," and who show their fitness for the place assigned to them sometimes by choosing a wife among their master's domestics. They commence as mere dispensers, pick up some minor surgery by looking on, and end by making themselves popular among patients of the class they belong to, and useful as general helps. A very exceptional master may now and then be found who cares to take up one of this sort and aim at making a gentleman of him; but as a rule, a surgeon has neither the leisure nor the inclination nor the inducement of interest to do so, especially as success is far from sure.

The lowering of the social position of assistants is peculiar to recent times; for the old-fashioned apprentice, whom the unqualified man replaces, was a rough school-boy often enough, but had at least the making of a gentleman in him.

5. The employment of unqualified assistants is an impediment to systematic education.

Both in London and in the provinces general practitioners are in the habit of seeking for assistance among the most industrious of the hospital students, and often apply to the deans and secretaries of the schools to recommend young men of good character. The students also find their own way to such engagements by advertisement and otherwise, in defiance of the warnings of their authorised teachers.

The unqualified assistants *in statu pupillari* are described as "neglectful of their clinical studies," backward and irregular in their clerking, and slow to profit by it. They are apparently "anxious to learn, but with minds otherwise pre-occupied." They hang about the school for years and years after the natural period of becoming qualified, and are not

unfrequently tempted away from their original ambition of being recognised practitioners. A few of the better and wiser among them slide off into other means of livelihood, the greater number remain as they are, a few defy the law, and practise for themselves without diploma. Yet even these last sometimes retain a touching attachment to their old school, displaying, "framed and glazed, the certificates of lectures" they failed to attend, and tickets of admission to the wards of which they had no time to avail themselves.

The authorities of hospital schools are entirely at one in condemning this abuse as subversive of their influence over education. Though I have sought diligently, I have not been able to find one dissentient voice to the unanimous opinion of the present teachers of schools that, "until the qualifying examination has been passed, there is no period in which a man could hold an assistantship without prejudice to his education" (Dr. Andrew, senior physician of St. Bartholomew's). "The pupils' studies are unquestionably retarded, because the time for study and reading are limited" (Dr. Phillipson, Newcastle College of Medicine). "We should strongly discourage the practice" (Dr. Wadham, Dean, St. George's). It makes the pupil's work harder, and interferes with his studies" (Dr. Scott, Warden, London Hospital). "Such men lose in proportion to the time they subtract from their hospital studies" (Dr. Taylor, Guy's). "Such men rarely go into the wards" (Dr. Morgan, Manchester School).

Dr. Leech, of Owens College, says of unqualified assistants *in statu pupillari*: "These men are the bane of a medical school. They are irregular in their habits, often idle and immoral. We have, like many other schools in the provinces, an undue proportion of these fellows, and we find them a source of unmixed evil."

The clearest justification of their coming to this conclusion is afforded by the following statistics of one year, taken from the records of St. Bartholomew's Hospital, by Dr. Norman Moore:—

"Excluding an American, who stayed only a few months, and students who entered for a single course, and for whose education the school was not responsible, there were entered in 1874—

Students for full curriculum	101
Of these there died	2
There have become qualified in the course of the eight years which have gone by	72

Of the remaining twenty-seven, eighteen got no further than the preliminary examination in arts, and have disappeared outside the scope of the present inquiry. Nine have passed some sort or part of the professional examination, but two of these have been led into more remunerative pursuits.

"The remaining seven still go on at the school, hoping ultimately to obtain some kind of qualification. They have all been unqualified assistants"; and it seems fair to conclude that it is this method of carrying on their studies which has uselessly protracted the period of education, and, at the same time, deteriorated its quality. Four of the best years of their lives have been wholly, irrevocably wasted.

The experience of other Medical Schools, such as those at Leeds, Newcastle and Bristol, Westminster, Middlesex, King's College, and St. Thomas's, is similar in its condemnation of the employment of unqualified assistants during their pupilage in private practice.

It is probably impossible to prevent this abuse by coercive measures directed against the students themselves; and, in fact, on their behalf a powerful plea is urged on philanthropic grounds. Those who take places as unqualified assistants are always poor, for all who can afford to live during their pupilage without this occupation know well how obstructive it would be to their progress and what a false economy. It is on the ground of pecuniary need that the main defence of the system rests. It offers a means by which needy youths, possibly destined to be an honour to our profession, may support the expense of their training. A case has been laid before the Committee of a dispenser, without any education but that of a national school and a chemist's shop, who was possessed with the ambition of being a medical man. He had no friends and no money. But he worked away with the aid of a fellow assistant, and got enough Latin, &c., to pass his preliminary. He remained a dispenser three years, saving every sixpence of a small salary, then got a place as assistant in a town where he could attend lectures, and passed, a few months ago, after seven or eight years of self-denial and hard work, his first professional examination. He now has taken an assistant

ship in the North of England, "until such time as he can save enough money to pay his fees for his qualification."

The training above described has been needlessly tedious, and for all those whose abilities, industry, and previous education fit them to fulfil a high destiny, ample provision is made by scholarships, exhibitions, bursaries, and paid appointments at the schools and hospitals, not to mention a few endowments at the Universities. To show how complete this provision is, take the instance of the youngest of the metropolitan schools at which a man can enter. It has no invested capital, and was built by private enterprise with money raised on debenture bonds. The annual entries have as yet rarely exceeded twenty; yet it is enabled, by the help of the staff and hospital governors, to distribute in scholarships and hospital and school appointments upwards of £840 a year by competition among those of the twenty students who are in need of it, the wealthier being usually restrained by worthy motives from competing, except for hospital appointments. This instance is selected in preference to some older and larger school with endowments, which possibly may give more, but does not so well represent the policy of the present time. Such open-handedness seems quite sufficient to aid effectually all those who are ever likely to justify the aid by aiding themselves in after-life; in fact, all poor students of superior or even average abilities. Dr. Tirard, Dean of King's College, also writes; "Of our really successful pupils, by far the larger proportion are men who from poverty have been led to work hard for scholarships in College and University. I cannot remember one, during my connection with King's College, who has taken a good position as a result of working as an unqualified assistant."

Moreover, some scholars can employ their evenings in mechanical literary work, such as translating, indexing, correcting proofs, reviewing, reporting, &c., which does not interfere with their presence in lecture-room or hospital.

Other modes of adding to their incomes might be enumerated, more open to objection perhaps than those above mentioned, but still far less engrossing than the toil of an assistant.

The protraction of systematic technical education is a serious abuse. It breaks the natural connection of the elementary and practical parts by interposing an interval between them. For example, if a pupil's knowledge of anatomy has had time to grow rusty, he is less able to profit by clinical instruction. And this failure reacts also upon the retention of the science, for if he does not fully profit by his clinical instruction, he does not have the half-forgotten anatomy impressed upon his memory, as at an earlier period it might have been impressed.

If a young man is naturally dull, and has not compensated his dulness by industry, and is at the same time in narrow circumstances, it cannot be any boon to himself or others that he should be enabled to enter the medical profession. It would surely be better that, like unsuccessful barristers, artists, soldiers, sailors, and those who are rejected from the Civil Service, &c., he should embark in another and less responsible pursuit for a livelihood. Yet there is no doubt much to be learnt in the position of an assistant—much that is very valuable in after-life to a practitioner—much that cannot be taught in a hospital. It would be a firm step forwards in professional education if students had the advantage of both the two schools of mental training, without either impeding the good influence of the other.

To put this matter in various lights, the opportunity is taken of introducing the opinions of several persons, either actually engaged in education, or otherwise officially interested in the promotion of professional skill among junior practitioners. The opinions have been given in answer to letters addressed to them on the subject.

Dr. Shepherd, Dean of St. Mary's School, says: "As to the question you put to me whether it would be well to insist upon an assistantship, or a position of responsibility at a public institution before registration, it settles itself. Very few indeed from our school go without some introduction of the kind into practice. The best men get it through hospital appointments, house-surgeoncies, &c.; others by a partnership—happy if they don't pay for it—for a time. The University of London insists upon a six months' responsibility of hospital or workhouse patients before candidates can offer themselves for the M.B. Others go to sea."

Mr. G. A. Brown, Surgeon to Tredegar Iron Works, writes: "In order that newly-qualified men may be better fitted for their duties as curers of disease, some modified form of pupillage should be enacted or (which would perhaps be the better course) diplomas should be withheld until

evidence could be afforded that some experience in medical practice had been obtained."

Dr. Eddison, late Secretary of Leeds Medical School, writes: "I do not think it would be viewed as a hardship if an assistantship, after qualifying, were made compulsory, provided that a year's house-surgeuncy or house-physiacy were admitted in place of it."

Dr. Andrew, Senior Physician to St. Bartholomew's Hospital, says: "My friends among our students often ask what they ought to do for the first year after qualifying. If they can afford it, and can trust their industry, I advise them to go abroad for a year. If they cannot do this, then to take a good assistantship."

Dr. Andrew questions the wisdom of making this advice compulsory, from a fear that there are not enough places vacant for all the candidates who pass. There probably, however, would be sufficient, if Dr. Eddison's plan of utilising the resident posts at the provincial and metropolitan hospitals were to be systematically adopted.

Mr. Marrant Baker thinks the practical knowledge to be acquired by familiarity with disease, on a less formal footing than that on which it is seen in the wards connected with a school, is very important. He suggests that it might be gained at a provincial hospital *before* entering at a recognised medical school.

Mr. George Johnson says: "I have no doubt that the spending a few months as an assistant after the final examination would be useful to most men. But I think it would be a hardship in many cases to make it compulsory."

Dr. Norman Moore, Warden of St. Bartholomew's College, thinks "it desirable that candidates, after qualification, should hold some resident medical appointment. If the vast opportunities of workhouses and sick asylums were properly used, this might easily be done. I think any resident appointment better than an assistantship."

"If all the possible resident appointments in London, in cases where there is no school, were tabulated, and the appointments to them apportioned numerically to the several schools in proportion to the number of students qualifying, I think it would be possible for every London student to hold such a post before registration. . . . The third summer seems to me the easiest time for attendance on midwifery."

Dr. Moore gives a sketch of a complete curriculum, concluding with "end of fourth summer, qualifying examination. Then resident appointment six months, then registration."

Dr. Tirard, King's College, London, writes: "It would certainly be desirable for candidates to spend a certain time as assistants, or as residents in town or country hospitals, before registration. The present rule, which allows a man of private means to take a practice as soon as he is qualified, is not, in my opinion, calculated to improve the standing of the profession or the welfare of the public. . . . For the majority who qualify it is well that circumstances often compel them to commence work as assistants or residents, thus forcing them to be still, to a large extent, under the guidance of seniors."

Dr. Scott, Warden of London Hospital College, writes: "Our students are strongly urged to press on and get qualified *before* seeking employment."

Dr. Allchin, Dean of Westminster Hospital School, approves the plan of requiring attendance for (say) six months as assistant to a general practitioner after the period of hospital study, "after the qualifying examination, but before registration. . . . It would effectually meet the present difficulty and objection to unqualified assistants. . . . The knowledge men would get by such a plan," he says, "they cannot get in an hospital, and yet it is most essential, for the want of it seriously diminishes the practical capabilities of men when starting in practice for themselves."

(To be continued.)

A NEW process for meat preserving has been discovered by Signor Pavesi, who is said to have succeeded in keeping pieces of meat for years without their flavour being impaired. During the whole time that it is required to preserve the meat, it is to be kept in a pickle consisting of water slightly acidulated with nitro-muriatic acid; and when required for use, the meat is dried at a temperature of about 60° Fahr. To avoid a slightly brown colour, the meat may be steeped in plain water before being dried.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JUNE 6, 1883.

LORD MORLEY'S COMMITTEE ON THE ARMY MEDICAL DEPARTMENT.

THIS important Report, to which we referred in our last, has now been issued, and will naturally be read with much interest by medical officers of the Army as well as those connected with them in civil life. While the medical officers have obtained general and warm praise for their care and removal of the sick and wounded from the field of battle, many serious and disagreeable facts have been brought to light in the general nursing and cooking arrangements for the proper care of the sick, very much as they were in the Crimean war, apparently the result of War Office checks and counter-checks, and the administrative deficiencies of some. Medical officers cannot regret that such facts are brought to light should the result be a final and common-sense arrangement of departmental duties in the future. The Committee believe that many of the inconveniences complained of were rather the result of the way in which the departmental system was worked than the fault of the system itself. Can this be wondered at when, as does sometimes occur, men are promoted as they come to the top of the list to be senior departmental medical officers with little or no regard to professional ability or merit beyond that of pure seniority? We assert without fear of contradiction that, as long as there is no system of non-selection of such individuals, administrative failures must follow, and with this the depreciation in the estimation of the Army and

the public of the credit and *prestige* of the medical staff. The whole gist of Lord Wolseley's evidence tends to show that in his opinion the members of the Medical Department did not assume to themselves in emergencies the full responsibilities which their position involved, and expressly stated that “if an officer in the position of a medical officer in charge of a hospital finds that the patients in his hospital are not receiving what they ought to receive in accordance with his ideas of what the sick and wounded ought to have, if it is possible for him to obtain it in any way, it is his bounden duty to do so.”

To this we say—How could a medical officer, as a matter of fact, take upon himself of his own initiation to ignore and over-ride the regulations of the Service? Simply he could not if he dared, and dared not if he could. All he could do was to represent to the commanding officer the condition of things. It was for the latter to issue the required orders on the subject.

We are glad to find that individual control over a hospital is to be still vested in what in future, we hope, will always be especially-selected medical officer, in whose prudence and common sense the Director-General may confidently rely. The regular and systematic inspection of an hospital under such an officer can only redound to his credit and that of the department. Punishment for minor offences will remain with medical officers, the more grave offences being relegated to military authority—a system which prevails in India, and appears to work well. The Quartermaster and Steward are to have their duties more clearly defined; medical officers are to exercise a personal supervision over the hospital subordinates; and the medical officer in charge is to live as near his hospital as possible; and in the larger hospitals there is to be a resident surgeon. We must say that the system which exists at some stations, apparently with the tacit sanction of principal medical officers, of allowing medical officers in charge of military hospitals to live sometimes miles away, is most detrimental to the good of the service and of the institution over which they preside. Nursing sisters are to be employed in hospitals with over one hundred beds to superintend the orderlies. Medical officers appointed to attend officers and their families are to have quarters in barracks, or reside as near the barracks as possible. The medical service of the Household Troops is to be assimilated to that of the rest of the army. Opportunity of practice with war equipment during peace is to be afforded. The evacuation principle, under which sick are constantly sent to the base, is to be checked, and each regiment is to be supplied with a pair of field panniers and surgery tent, a corporal and private of each battalion assisting the medical officer, and soldiers are to be trained for this service. Bearer companies are to be reduced to one-half their establishment, sections attached to field hospitals, and provision made for mounted bearer companies. Field hospitals are to be distributed by brigades, and the nursing staff increased to 1 to 7 patients, and all packages are to be capable of being transported on mules. Medical officers are to be held responsible for procuring the best quality of supplies procurable. Civilian cooks may be hired to superintend cooking. But it is not indicated how or where they are to be obtained on the field, or before the enemy.

We are glad to see that the Committee recommend that the examination for promotion is to be restored, a reform which will do much to raise the professional reputation of the service, especially if gentlemen who fail to keep up their professional knowledge are retired with the gratuity of their rank as in the combatant branch. The Army Hospital Corps are to be amalgamated with the Medical Department into a Royal corps, and the uniforms assimilated, a most important recommendation, which, if carried out, will do much to foster *esprit de corps*. As there appears to be a strong feeling in favour of the traditional scarlet of the old medical staff amongst medical officers, we trust the system of levelling up, and not levelling down, will be adopted, and opportunity taken of getting rid of that most antiquated and unsuitable of head-gears, the cocked hat, and the helmet substituted. We also hope no long-winded title will be adopted. Of the many suggested, Royal Surgeons, Royal Medical Staff, or Royal Medical Corps appear to be the most appropriate. We also think the opportunity should be taken of conferring on medical officers ranking as Lieutenant-Colonels of some distinctive designation, such as Senior Surgeon-Major, as proposed originally by the meeting of medical officers at Aldershot some years ago, and that measures for quickening promotion to the rank of Brigade-Surgeon will be devised. It is not an unreasonable demand upon the part of the senior qualified Surgeons-major that this rank should be reached not later than the completion of twenty-five years' service, the late War Office Committee having recommended that they should attain it at twenty-two and a-half. These reforms, with limit of tenure of administrative appointments to five years, or up to sixty years of age in cases only of exceptional merit, specially recommended by the Director-General, would undoubtedly add much to the efficiency of the Medical Department and render it still more popular.

CONCEALMENT OF DISEASE UNDER COMPULSORY NOTIFICATION.

(Continued.)

DR. CARTER, of Liverpool, writing on the effect of compulsory notification as a factor in producing concealment of disease, to a contemporary, says:—

Arguing from what seems to us to be the inevitable tendency of human nature, we believe that the exercise of the powers in question must lead to the concealment of disease; that the heads of business houses—and especially of small businesses—dreading the notification that must follow if a medical man be called in, and which may lead to their children being forcibly removed from their homes, and their business diverted into other channels, will not summon medical aid; and that, in the absence of those precautionary measures which, by the private medical practitioner's directions, are all more or less taken, disease will spread; though it may spread under other names than those of scarlet and typhus fevers. But we shall, of course, be told that to argue from the inevitable tendencies of human nature would be to show ourselves theorists, that your practical men must have facts. To facts, therefore, we will turn; and, difficult though in the nature of things it must be to prove concealment, I think that the evidence that it does exist is overwhelming.

Firstly, let me ask your consideration of a few figures,

taken from such reports of medical officers of health as have come to my hand. In Blackburn, during 1881, there were 103 notifications of scarlet fever, and 23 deaths, or 1 in every 4. In Bolton, during the fifteen months ending December 31st, 1880, there were 702 cases reported, and 112 deaths, or one in every 6.2. Or, turning to another disease: in Bolton, during the same period of fifteen months, there were 102 notifications of typhoid fever, and 23 deaths, or 1 in every 4.4. In Blackburn, during 1881, there were 281 notifications, and 68 deaths, or one in every 4.2. Now, I would ask any medical man here, whatever his practice may be—even if it be among the very lowest and poorest of the land—if he has ever known, in the most serious and fatal epidemic, such ghastly mortalities as these? The deaths from typhoid fever in Blackburn and Bolton were half as high again as at the London Fever Hospital, where, from reasons given by the late Dr. Murchison, they must always be exceptionally high. The only conclusion that seems possible from such figures as these is, either that many cases are concealed, and hence the mortality is made to appear high; or that the diseases themselves, if at all of a severe type, are fearfully fatal to the individual, where such powers as those possessed by Bolton are carried out.

But there is unexceptionable evidence of a different kind that concealment prevails. Thus, a medical officer of health for one of these towns writes: "No. 2 was a case where there were three other children in the house, but two of them were removed in the night, after I had given my certificate." From another gentleman I learned that a certain course was adopted, because parents would "wriggle out of giving notice in mild cases of scarlet fever, declaring it measles."

Again, we find that in Dublin, although no law exists to compel the physician to notify, the effect of such a law is foreshadowed by the result of a limited notification. The dispensary district medical officers are the *ex-officio* district medical officers of health and the servants of the Town Council, and, as such, they are under orders to report infectious cases to the Public Health Committee. They have done so, and the Corporation disinfectors have thereupon been sent to adopt the necessary sanitary precautions, and have been obliged to do so with every consideration for the feelings and the interests of the patient's family, inasmuch as no special powers existed to effect sanitation or isolation by force. Nevertheless, it is notorious that the result of this very limited system of notification in Dublin has been to exclude the dispensary district medical officers from practice amongst the poorer classes, and to throw the treatment of infectious cases into the hands of "club" doctors, who, not being corporate officers, are not obliged to notify, and, in fact, do not do so. The infected poor of Dublin, in many instances, even deny themselves the necessaries of life in order to be able to pay a private practitioner, rather than resort to the dispensary doctors, and the Public Health Committee of the Corporation have publicly stated this fact in their official reports. They say—

The attention of the Public Health Committee was drawn to the fact of concealment of infectious disease, and the serious consequences of neglecting to call in medical aid until the illness is of several days' duration. A child recently took ill with fever in Church Street, and no medical man was summoned to see the patient; two grown persons have since contracted fever in the same room from the child, and they are now dangerously ill, so much so that the cases could not be removed with safety in the hospital cab, but had to be conveyed on a stretcher to the Hardwicke Hospital. The last two cases were ten or eleven days ill before any medical man saw them, and if

left in the room would probably have died, as no person in the house would attend to them. The fear of incurring the censure of the landlords of tenement houses in many instances appears to be the chief reason for not seeking medical advice in time; with others the dread of removal to hospital is the motive.

We say advisedly, that in towns in which compulsory notification is the rule, concealment does take place to a very serious extent, and we ask the advocates of compulsory notification by the physician, can you prove by statistics of the number of persons who died *unattended by a qualified medical practitioner*, within towns in which notification is compulsory on the medical attendant, that the system has not caused concealment of disease, or driven the population into the arms of quacks or prescribing chemists?

The following are the regulations relating to death registration:—

a. Every registered medical practitioner in attendance on deceased must give to the person who is to give the information for registering the death a certificate of the cause.

b. The person who gives the information must deliver the certificate to the Registrar, under penalty of 40s.

c. The Registrar must state cause of death when so certified in his record; but when the deceased has been attended by no one, or by an *unqualified practitioner*, he must enter the death as "uncertified."

d. The Registrar must give, gratuitously, a certificate for burial.

e. Every such certificate must be handed to the person who buries, under penalty of 40s.

f. If no burial certificate is produced, the person who buries must at once inform the Registrar-General thereof.

g. No child's body shall be buried as still-born without special precautionary certificates.

Under the law of death registration, every information desired is available, and it is, therefore, easy for a medical officer of health to compare, day by day and year by year, the mortality from any class of disease, and to illustrate the actual results from notification by proving that zymotic deaths have been reduced in number by its agency. Moreover, an examination of the death certificates would show to what extent persons dying from infectious disease had been attended by quacks or prescribing chemists, or left without attendance; and if it appeared upon investigation that the percentage of persons who died without the ministrations of a qualified practitioner had materially increased as a sequence of the introduction of the notification system, we should then be entitled to assert that the public had been driven to resort to unqualified practitioners, who are not amenable to notification law, in order to conceal the existence of the infection, and, *ergo*, that the disease was being secretly disseminated in spite of the notification law.

We again invite medical officers of health to test the soundness of our conclusions, and the truth of the statements which we have quoted above, by showing that the proportion of persons who have died without the attendance of a physician has not increased as a sequence of compulsory notification, by which means only can they satisfy the public that wholesale concealment and dissemination of infection is not the actual outcome of the system, as it is obviously the natural result.

ICHTHYOL.

A NEW drug has been recently introduced to the notice of pharmacologists which bids fair to prove of considerable value. It has been described by G. P. Unna, of Hamburg, a well-known investigator in the domain of therapeutics, as a tarry-looking substance of the consistence of vaseline, and as possessing a peculiar odour. For reasons which will be presently stated, it has received the name of Ichthyol. It is said to be partly soluble in ether and partly in alcohol, and totally in a mixture of the two. It forms an emulsion with water, whilst with vaseline and fat it may be mixed in any proportions. It contains a considerable proportion of sulphur—about 10 per cent., which is so intimately united to the remaining constituents that it can only be separated by destruction of the ichthyol.

According to Rudolf Schroeter (*Deutsch. Med. Zeit.*, 17/83), it is obtained from a bituminous mineral found in the neighbourhood of Seefeld in Tyrol. The colour of the stone from which it is obtained is a clear brown and brownish black; its percentage of bitumen varies between 10-60. In the matrix in which the stone is found are a great number of fossil imprints of fishes, and some petrified fish were even met with. In consequence of this, Professor Fritsch has concluded that the bitumen is the animal remains of ancient marine animals and fishes,—whence the name.

The bituminous stone is subjected to dry distillation in iron retorts, the result of the process being the production of a tarry like substance of a peculiarly disagreeable odour. From this after long standing a thin fluid oil is separated. After thorough purification it is treated with concentrated sulphuric acid. The superfluous sulphuric and sulphurous acids have then to be separated from the sulphate thus formed.

Unna has made numerous experiments with the substance thus prepared, both in skin and other diseases.

From a paper contributed to the *Monatsch für Pract. Dermatol.*, 11 & 12/82, and noticed in the *Deutsche Med. Zeit.* above quoted, we learn that it has been employed with good results in every form and stage of eczema, care being taken, as soon as its characteristic effects have been produced, to gradually reduce the strength of the application employed, exactly as when sulphur preparations are made use of. It must be used in a more diluted form in the case of children than is necessary in adults (10-20 per cent. in ointment for children, 40-50 in adults). He has used the following form in an obstinate case:—

Lythargyri, 10,0;
Coque c. aceti, 30,0;
Ad reman., 20,0.

Adde—

Olei olivar., adipis, ana 10,0;
Ichthyoli, 10,0.
M. Ft. ungu.

In acne rosacea he saw good results from its employment, but nothing special in psoriasis.

In a later communication to the last-named paper he gives his observation on its employment in other forms of disease. Of its employment in cases of acute

and chronic rheumatic arthritis he says: "I believe from my few cases I may say, that up to the present there is no external application of equal efficiency." "The good effects in very chronic cases which have already gone on to deformities of the joints, contractions of neighbouring muscles, thickening of ligaments, &c., seem to me by my own observations and those of other colleagues to be indubiously certain, although I have not observed any absolute cure in such cases."

It has proved of signal service also in veterinary medicine, the rubbing in of the oil having completely cured many cases of stiff joints in horses, even in those that were otherwise doomed to the *coup de grâce* of the knacker. It has been used with great advantage in acute lumbago, and in "rheumatic" pains in the head. In the latter affection it has been employed in the following form, viz., ichthyol 10 parts, ol. ricini 20, spiritus 100, by means of a drop-glass, spray, or "dabbed" on with sponge. The odour may be rendered less offensive by the addition of a spirituous solution of camarin or vanillin. He has not found it useful in simple neuralgias. Some rheumatic patients have stated that the simple inhalation of the fumes of the drug has relieved their pain. If added to a large quantity of water and heated, the ichthyol is decomposed, giving off H_2SO_3 , S, &c. Employed by way of inhalation in this manner, Herr Unna has observed remarkable results in affections of the respiratory tract. He has employed it recently in angina follicularis, commencing angina phlegmonosa, and angina catarrhalis, in the above forms, painted on the parts hourly, or in the following as spray: Ichthyol 5, ether and spirit of wine, each 50. He has also employed it in specific catarrh of the urethra. In this affection its principal effect is the relief of pain, and he recommends the addition of corrosive sublimate if a germicide action is desired.

In regard to the undesirable concomitant effects of the local application, Herr Unna has observed only the frequent, but not constant, occurrence of local and general hyperidrosis. He has also observed the frequent eruption of miliaria, from its effect in blocking up the sweat pores.

We have not space to follow our author through the whole of the article, but enough has been said to show that in all probability we have in ichthyol a therapeutic agent of no mean efficacy.

Notes on Current Topics.

Nephrectomy in America.

THE operation of nephrectomy, to which a considerable amount of attention has been devoted both here and on the Continent during the last few years, is becoming in America also a more commonly-adopted method of relief than could at one time have been supposed at all probable. A case is reported in the *Boston Medical and Surgical Journal* in which Dr. S. W. Gross undertook the operation on April 20th last, the patient being a lady, fifty-nine years of age, of spare habit. Three months prior to the date named the patient had commenced to experience

much pain from the presence of an abdominal tumour, which, however, was noticed then for the first time. After careful examination Dr. Gross came to the conclusion that the growth was a cancerous kidney, and proceeded to remove it through a median incision as for laparotomy, the right side being the one affected. The kidney was found to be transformed almost entirely into a cancerous mass, the amount of healthy tissue remaining being very small. At the same operation, the gall bladder being discovered to contain several calculi, cholecystectomy was performed. For a time the patient did well, pulse good, temperature normal, but on the second day peritonitis supervened and death took place.

An Unusual Occurrence.

At a recent meeting of the Philadelphia College of Physicians and Surgeons a patient was exhibited on whom Dr. John Rhea Barton performed resection of the radius so long back as 1828, or fifty-five years ago. The patient, a woman, is now 64 years of age, and has used the arm ever since the operation was performed.

Kairine.

ANOTHER new drug has been recently introduced to the notice of the profession, which from published reports appears well worthy of being brought prominently before our readers. On the present occasion the first account of its properties comes from Vienna. Last year an attempt or many attempts were made to find a substitute for quinine, and these resulted in the synthetic manufacture of chinoline, which, as many of our readers will be aware, was formed artificially out of aniline, nitro-benzol, glycerine, and sulphuric acid. The drug thus made had anti-febrile properties. Other experimental efforts were subsequently made, and Otto Fischer, Koenigs, Bedal, and others succeeded in producing out of chinoline a preparation technically described as methoxychinolintetrahydride, but to which they gave the name of Kairine. It is an oil that unites with hydrochloric acid. Professor Ludwig gave the above account at a recent meeting of the Royal Medical Society of Vienna, and further gave some account of the results of his own observations and of those of others. One striking effect of taking kairine was shown in the urine of the person taking it. It became brown, or olive green, and more rarely grass green. It appeared as if some kairine went over in the urine unchanged; it becomes still darker by exposure to air. The kairine urine constantly contained bacteria in considerable quantities, so that it would almost seem as if the drug afforded a good soil for their growth.

Professor Drasche, who introduced the drug into Vienna practice, then spoke, and gave the results of a series of observations. In large doses—0.5 grain every two hours, up to 3 grains in the twenty-four—a considerable fall of temperature took place, but accompanied by shivering and grave symptoms of collapse, so that he afterwards gave it in 0.2 grain doses until 2 grains had been given in twenty-four hours. The dose of 0.3 grain caused a fall of 3.4° C. in a case of pneumonia, and in another a dose of 0.3 grain reduced the temperature 4.3 C. degrees. In two cases of erysipelas the temperature was also much reduced by

bi-hourly doses of 0.5 and 0.2 grains. Somewhat similar doses produced similar effects in the pyrexia of phthisical patients. The drug was also administered hourly or bi-hourly in 0.2 grain doses in a severe case of typhoid with bloody stools. During the first days of administration, the temperature was reduced on the average scarcely 1° C., but some days it fell to 38° C. (100.2 F.), and remained at this point several hours. Later, the daily average diminution of temperature reached 2° C. If the kairine was temporarily omitted, the temperature immediately rose. Doses of 0.3 grain gave rise to rigors, collapse, and feebleness of cardiac action. Professor Drasche considers that kairine is superior to all other drugs as a promptly-acting anti-pyretic, and believes that it has a great future before it.

Clinical Society's Committee on Spina Bifida.

AN announcement was made by the President of the Clinical Society on the 25th ult., to the effect that the Committee appointed to consider and report on Spina Bifida and its Treatment had not yet concluded its labour. In consequence, therefore, its report will not be presented during the current session, which ended on Friday last; nor can it be included in the next issue of the Society's Transactions. The Committee have accumulated a very large and valuable amount of information, and are anxious to make their report as complete and exhaustive as possible. They desire to have it generally known that any gentlemen who may have cases they are willing to communicate will do so without delay, and that specimens will be especially acceptable in illustration of the subject.

Students and the Medical Bill.

ON Friday last Mr. Mundella received a deputation from the Medical Union Society in favour of the new Medical Bill. The objects of the deputation, which was introduced by Dr. Farquharson, M.P., were briefly explained by the Honorary General Secretary of the Society, Mr. Charles H. Wade, who expressed the gratitude felt towards the Government by students of medicine for the improvements promised by the Bill. It was especially urged, however, that the interests of students demanded the restoration of the "title clause," and that amendment of the Bill in this direction would be no more than an act of justice to the many young men who, by-and-by, would be influenced by the operation of the Act. In reply, Mr. Mundella said that, although he had received many deputations on the Bill, none had interested him so much as this, for he felt that in a question so deeply affecting students themselves the expression of their particular views was of value and importance. He said he was much impressed by the statement Mr. Wade had made, and held forth considerable hope that the concessions sought for might eventually be granted; certainly the matter in question had been put before him more clearly and forcibly than at any time previously. The deputation then, after thanking the Vice-President of the Council for the attention he had given to it, withdrew; and the Society may be congratulated on having very satisfactorily advanced the views of its members.

Murchison Memorial Scholarship.

THE examination for the Murchison Memorial Scholarship, held this year in Edinburgh, has resulted in its award to Mr. G. C. Dickson, M.B., C.M., House Physician at the Royal Infirmary. The examination for the scholarship was partly written and partly oral, and included examination of patients, with reports and commentaries on the cases, problems in treatment and pathology, and descriptions of specimens. The successful candidate graduated at Edinburgh University in 1882, having gained honours of the second class.

The Royal Red Cross.

A LIST has recently been published in the *Gazette* of ladies on whom the new order of the Royal Red Cross has in the first instance been bestowed by the Queen. Six members of the Royal Family head the list, and after them come five-and-twenty other recipients of the order, including Miss Florence Nightingale, Mrs. Deeble, lady superintendent at Netley, Lady Strangford, and Lady Lloyd-Lindsay. In the institution of this distinction for the women who by devotion and self-sacrifice have done incalculable good to the cause of humanity, a step has been taken which is thoroughly significant of the deep interest always taken by Her Majesty in the welfare of her people, and her appreciation of the valuable nature of the labours of those who essay to relieve the pangs of sickness and to soften the horrors of war.

The Unqualified Assistant again.

MR. EVANS, surgeon, of Pontlottyn, and his unqualified assistant, have been prosecuted, at the instance of the Registrar-General, for unlawfully and wilfully making a false certificate of the death of a child who had been attended by the assistant and had not been seen by the principal, in consequence, it was alleged, of his being suddenly called away on the day of the child's death. It was admitted that the certificate was filled up by the assistant, but that the signature was the principal's. The stipendiary, while convicting the assistant and fining him £5, declined to convict the principal on the ground that the evidence was insufficient to show that he was a party to giving and making the false certificate. He admitted that it was a reprehensible act to leave blank certificates about signed by the principal. But this did not necessarily involve the offence named in the summonses. A case for a superior court was granted.

Small-Pox in Dublin.

WE regret to learn that a case of small-pox arrived in the Liffey on Monday last on board a foreign barque. At once the Superintendent Medical Officer of Health, Dr. Cameron, took the most active steps to prevent the dissemination of the disease. The patient was at once taken to the floating hospital at Ringsend—which it was recently most foolishly proposed to sell—and the ship in which he arrived was put into strict quarantine. A special surgeon was engaged to remain on board the floating hospital night and day. Up to the period of our publication there has been no indication of a spread of the disease.

Death of Dr. Wilbur.

INFORMATION comes from America of the death of one of the most eminent and widely-known of asylum superintendents in the States, and a physician who was familiar, by name at least, to a not inconsiderable number of the profession here. Dr. H. B. Wilbur, Superintendent of the New York State Idiot Asylum at Syracuse, died on May 1st, after a service of no less than thirty years in the post left vacant by his decease. As a pioneer in the theory that care and kindness combined would suffice to effect improvements, in the condition of the unfortunate beings in his charge, Dr. Wilbur earned and has received the grateful thanks of an appreciative number of his followers, and in the work accomplished by him in the particular line he made his own especial study he has laid claim to be remembered as a benefactor of the first order. To his friends and acquaintances his loss will be a severely-felt blow, and all will regret that he has so soon, at 63 years of age, been cut off from the continuance of the labours he turned to so good account.

The Royal Medical Benevolent College.

THE annual general meeting of the Royal Medical Benevolent College was held in the Committee Room, Soho Square, on Thursday last. The treasurer occupied the chair, and the secretary read out the list of successful candidates, when it appeared that the recommendation of the committee of examination as to the most urgent and deserving cases had met with the almost unanimous approval of the body of Governors, both the vacant pensionership and Morgan annuitant being respectively elected, together with seven out of the nine foundation scholarships. The Report stated that the working of the school was now all that could be desired, many of the boys having taken honours and obtained scholarships in and out of the College, and one or more had passed directly from the school into the Universities. It is a subject of much regret to find the funds of the College are still in a languishing condition. The expenses of the institution exceed the receipts by several hundreds of pounds—a fact, we hope, which needs only to be made known to ensure a ready response from the wealthier members of the profession.

The Clinical Society of London.

JUDGED by the attendance of members at the extraordinary meeting of the Clinical Society on Friday evening, the experiment of having an extra "clearing" night was not a success. In other ways, however, it probably answered all expectations, for quite a succession of papers was read, but little discussion being indulged in. Possibly a larger gathering might have been secured had longer notice of the additional meeting been given; but as it was arranged with a view to enabling a clearance of all the papers in hand with a view to publication in the annual volume of Proceedings, no doubt all that was required was obtained. It would, however, be well for the Council of the Society to remember that discussion is a very valuable part of the programme of its meetings, and that a precedent of the kind encouraged by Friday's occurrence may, if unduly strained, result in a certain disadvantage.

Oxalurea.

WHETHER the presence of oxalate of lime crystals in the urine is a primary cause of a very unsatisfactory train of symptoms, or is itself only a symptom of a constitutional state, the conditions under which it occurs are sufficiently troublesome to deal with to demand our earnest and close attention. The cases in which it occurs usually progress very slowly towards restored health. Even the best text-books upon abnormal states of the urine pass lightly over its true significance as a symptom, and are very meagre in their directions as to treatment, &c. Dr. J. L. Bauer, of St. Louis, reports the details of a case of this nature that lately came under his notice at some length. The patient had been for many years the subject of venereal excesses, both by self abuse and sexual concourse, and had induced a highly irritable condition of the urethral membrane and prostate gland. The lips of the meatus were reddened and everted, the passage was highly sensitive, micturition was frequently painful, muco-gelatinous discharges took place from the urethra, and the urine presented mucous flakes. The prostate gland was enlarged and tender. The patient suffered from indigestion, hypochondria, general pains, constipation, and partial impotence. The patient's attention had never been drawn to the presence of a sediment in the urine until some time after coming under Dr. Bauer's notice, when he passed a large quantity of small concretions, which were found to be composed of oxalate of lime. The hyperæsthetic condition of the genital organs was overcome by the administration of a mixture, as follows:—

R Potass. acetatis, ℥iiss.;
Ext. buchu fluidi, ℥ss.;
Ext. hyoscyami, gr. xij.
Syr. gentianæ, ℥j.
Aqua destil. ad ℥vj.

M. A tablespoonful every third hour; and the passage daily into the urethra of a suppository containing grs. x. of iodoform and grs. v. of eucalyptol oil (Landers).

After the passage of the small calculi the patient was placed on five-drop doses of the dilute nitro-muriatic acid three times a day, to be increased to toleration; and his bladder was washed out with a solution of grt. 1½ of pure nitric acid in ℥ij. of water. The treatment was followed by perfect recovery.

OWING chiefly to the magnificent weather of the past three weeks, the mortality throughout the United Kingdom has been steadily declining, and in most of the large towns last week it was much below the average. The highest annual death-rates from diseases of the zymotic class were—From whooping-cough, 1·2 in Cardiff and 2·4 in Birkenhead; from measles, 1·9 in Liverpool and 2·1 in Newcastle-upon-Tyne; from scarlet fever, 1·8 in Derby and 1·9 in Sheffield; and from "fever," 1·2 in Hull and 1·3 in Sunderland. The 28 deaths from diphtheria included 14 in London, 5 in Glasgow, 2 in Edinburgh, and 1 in Dublin. Small-pox caused 2 deaths in Birmingham, 2 in Newcastle-upon-Tyne, and one each in London, Liverpool, Leeds, and Sunderland.

menced, and continued to such an extent that after a few weeks the child was able, not only to move its legs, but make an attempt to stand. It unfortunately caught whooping-cough, and had to leave. The fifth and last case occurred in a child two years old. The disease came on insidiously, is confined to one leg, which, on admission, Feb. 4th, 1883, was shrunken and paralysed, with loss of reflex contractility. This patient is also having the moxa, and is now, without any other medicine, able, not only to stand, but to walk a little as well.

These cases, I may safely state, practically illustrate the value of the moxa, though I do not forget that it is open to say that something is due to the belladonna, nuxvomica, &c., contemporaneously administered.

But when we remember the chronic character of the disease, and the undoubted expenditure of the *vis medicatrix nature*, and the certainty in the first and third cases, and the probability in the second, that these or similar drugs had a fair trial and failed, it is impossible not to be convinced that the complete cure in one case, the great improvement in two cases, and the expected cure in the fourth case is due to the moxa.

I might conclude here, were I not anxious to show that the use of the moxa, which is undeservedly neglected, and which is not even mentioned by most of our popular therapeutic writers, can be supported as strongly by theory and argument as it has been just illustrated by practice.

It may, I think, be granted that counter-irritation in some form is frequently advantageous in the degenerations and chronic morbid states under review.

But it may nevertheless be useful to pause and ask ourselves what is the *rationale* of its curative power. In fact, for my purpose of showing the superiority of the moxa to other forms, it is necessary to do so.

Counter-irritation, broadly speaking, is of two kinds. The first may be likened in its effects to a kind of local depletion, as when a large fly blister is applied for a considerable duration of time, as in the early stage of acute inflammation, for example, over the lungs in pneumonia. The serum of the blood is withdrawn, and the subjacent congestion relieved. The second is similar in its action to the stimulating effects of strychnia and electricity, and is adapted to chronic morbid conditions, in the anæmic states of the system, and for the dissipation of old fluid collections. Its action may be illustrated by the use of firing in joint disease, and that of the moxa in the diseases in question. In both kinds the stimulant influence is exercised primarily through the nervous system, acting secondarily on the vessels of the part morbidly affected. Thus in the very early stage of acute inflammation we can easily understand the depleting effect of a good blister, the vessels still retaining some functional power.

The following experiment of Nauman will illustrate the reflex stimulant action of the second form of counter-irritation when applied to sclerosis of the cord. The head of frog was removed the medulla intact, and its mesentery exposed, and one thigh, after ligation of the blood-vessels, was separated from the body, leaving only the sciatic nerve unimpaired. On applying a mild galvanic stimulus to the web of the prepared extremity, and examining the vessels of the mesentery, the current in the vessels was observed to be quickened, and rendered continuous instead of wavy. A through current caused the vessels to separate from each other, and to appear more distinct. At the conclusion of the experiment the blood current assumed its *original rate*. In this way the vaso-dilator nerves are at first stimulated, and then, becoming tired, resume their normal state of quiescence, showing that, whatever form of counter-irritation is used, it must be reapplied at intervals. This experiment explains not only the action of electricity—an agent of the greatest utility in chronic spinal affections—but which sometimes, as in some of the present cases, failed (I may here state that I did not try electricity, as I wished to give the moxa a fair trial, but it was tried before by others); but it has a wider significance, explanatory of all cutaneous irritation on the circulation

through the action of the nervous system by a reflex operation.

If the stimulating action of electricity is similar to that of the moxa and some other forms of counter-irritation, in what, then, it may fairly be asked, does the superiority of the moxa consist? Having noticed the advantage of the moxa where electricity had failed, owing probably to the impairment of the receptivity of the nerve fibres or centres allotted to the conduction and presidence of electrical force, as shown by the want of electrical contractility, it appears to me not unreasonable to contend (and the slight and often non-impairment of common sensation confirms this view) that the centres and fibres associated with common sensation and the sensation of *heat and cold often remain intact*, while those connected with electricity are, in chronic cases, usually diseased. Even in loco-motor ataxy the often normal condition of the *superficial reflex excitability* is remarkable when we remember the total absence of the patella and other tendon reflexes. In this disease, also, the sensibility to heat and cold, &c., usually remains to the last. These things, at any rate, show the rarity of nerve fibres, and that consequently a therapeutic agent, whose ultimate result is the same, may differ greatly in power, owing to the freedom or blockage of the channels along which it is distributed. Thus far I have tried to explain the theory of the stimulating action of cutaneous irritation in general. I will now discuss the special advantages of the moxa, first saying a few words descriptive of this agent, including its history.

History and Description of the Moxa.

The physicians of Greece and Rome, who all used some form of counter-irritation, were not, as far as I can find out, familiar with the moxa, which would appear to be of Eastern origin. It was introduced into the West by the Portuguese soon after their earlier Eastern conquests, whether from India or China is not clear, though I may say that when in India I was informed by an intelligent Portuguese Eurasian that it was first carried to Europe by the physician of Albuquerque, the conqueror of India. The great surgeon Larrey became aware of its value during his Egyptian campaigns, and spoke highly of its utility; but in all the works on materia medica which I have referred to, except that of Stillé, who gives a good account of it, the moxa finds no place. Even the homeopaths, so prolific on the treatment of disease, have forgotten to make it conform to their great axiom.

The moxa may be made of many substances, such as the down of the various species of the artemesia, the agaric of the oak, flax or hemp impregnated with inflammable matter, or linen saturated with nitrate of potash. Larrey's moxa was an inch long and half-an-inch broad. This I consider too short, as its action would be too rapid and severe, and of the other forms above alluded to I have no experience. That which I myself use consists of a piece of brown paper about 15 inches long and 4 broad. This is saturated in a solution of nitrate of potash in proportion of ʒj. to ʒj. of water. A stronger solution, or one of chlorate of potash, is not advisable, as it is liable to burn with a flame, which should be avoided. This paper is dried and rolled into a cylinder, and is then ready for application. It resembles a short cigar without the tapering ends. To apply it, one end is set on fire and the other placed on the skin in the vicinity of the subjacent disease. The neighbouring parts should be protected with alum paper with a central hole, while the degree of heat can be moderated to any degree by the moxa holder or forceps, and freshened if necessary by blowing upon it. I always remove it before the burning part comes in immediate contact with the skin. In this way no scar or sore is ever produced, and it can be reapplied as often as necessary.

During its application the first degree of heat is attended with an agreeable sensation, which gradually increases, but is rarely severe, and has never been much objected to by my patients, who, on the contrary, seem rather pleased at the idea of the application, as the pene-

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE SCOTCH CORPORATIONS AND THE UNIVERSITIES.—At present a severe contest is going on between the Corporations and the Universities, and as usual much may be said on both sides. The Corporations claim that they existed before the Universities, and were the first to institute an examination in arts, condemned especially by the University of Edinburgh. This statement is especially true, especially on the part of the College of Surgeons. The Universities claim that they are *bond fide* teaching bodies: this is only partly true. The Edinburgh Corporations have always, though in a somewhat half-hearted way, fostered medical education. They have required the teachers of the medical school to pass an examination in the branch of study proposed to be taught, which examination is recognised by the Universities. For the professors in the University no such test is required, the only requirement for a professorship being the amount of interest he can procure, the methods of obtaining this being in many cases not the most creditable to the parties concerned. The Universities charge the Corporations with selling their diplomas. This is a dangerous weapon in the hands of both parties. Readers of old plays not well known to the present generation will have read of a certain Dr. Pangloss who obtained a doctorate from an ancient northern university, and the memories of St. Andrews have not quite died out. There is, however, one charge which the Corporations can bring against the Universities which is irrefutable, and that is, that the Universities, by allowing their teachers to examine their own pupils, have permitted a species of extortion which in some cases is simply disgraceful. The system has been disastrous in more ways than one. It has stamped men with high-sounding titles who were simply crammed with the crotchets of their teachers, and whose mental growth was dwarfed by the very institutions whose duty it was to enlarge the understandings of their *alumni*. The system has sapped the manliness from the students by turning them into cringing hypocrites and servile imitators. The Corporations, on the other hand, whatever may have been the failings in their examinations, have always allowed a wider field for their candidates, and the candidate and examiner have met on a broader platform. The abuses just mentioned could easily be met by taking the examining power out of the hands of both parties—that is, as far as the minimum State examination is concerned.

THE FUTURE OF THE EXTRA-MURAL SCHOOL, EDINBURGH.—If the Medical Amendment Bill becomes law, the outlook of the Extra-Mural School is dark enough, and medical education in Scotland will suffer a fatal blow. To make this statement clear, we will mention the facts of the case as they will stand if the Bill passes in its present form. The final examination in medicine, surgery, and midwifery is alone to be conducted by the new Board. The examinations in the primary subjects are to be conducted by the Corporations and Universities, to which latter the great bulk of the students will, as now, be attached. The professors enjoying their right of examining will fill their classes by demanding a knowledge of their crotchets, the result being that the Extra-Mural teachers will have to close their lecture-rooms, and the whole monopoly of teaching will be thrown into the hands of the Universities. There being no rivalry, the teaching will soon degenerate. Those who have at heart the welfare of medical education in this country will take care lest the evil we have pointed out become an established fact.

A COUNTERBLAST FOR SIR WILFRID.—In the course of his examination before the Crofters' Commission at South Uist, Dr. Donald Black, the parochial medical officer, said that the public health was pretty good, but in spring and winter there were numerous cases of chest diseases due to the reduced state of the body. Pulmonary complaints and chronic rheumatism were common ailments; scrofulous affections were not common. The idea that consumption was much more rare in the island formerly than it was now was, he believed, owing to the fact that in former times they were less able to diagnose properly. There was a considerable liability to fevers, such as typhus, owing to the close proximity of the houses to cattle, and the bad drainage. The children were, upon the whole, fairly clothed. "*Giving tea to the children was quite prevalent, and, in his opinion, injurious.*" Milk, of course, was the best thing they could get, but in the event of their not being able to get it, *he would recommend a cheap beer*, beginning with children at from one to two years of age.

ANTI-VIVISECTION CONFERENCE IN EDINBURGH.—At a thinly-attended conference of those opposed to vivisection, held in Edinburgh on the 26th ult., a resolution in which the conference viewed with alarm the statement by the Home Secretary, that he had accepted the assistance of the "Association for the Advancement of Medicine by Research" in carrying out the duties imposed on him by the Vivisection Act, 1876, and disputed the statement that under the Act demonstrations in illustration of lectures were prohibited, was adopted.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 26th ult., were at the rate of 83 per 1,000 per annum, against 35 in the preceding week, and 28, 22, and 27 in the corresponding periods of 1882, 1881 and 1880.

UNIVERSITY OF EDINBURGH.—The following scholarships have been awarded:—The three Vans Dunlop Scholarships in the Faculty of Medicine were awarded to—one in natural history, including geology and botany, to George L. Gulland, M.A., B.Sc.; one in anatomy, physiology, materia medica, and pathology, of £100 a year, tenable for three years, to Fourness H. Simmons; and one in the same subjects to M. S. Altounian, which had been resigned by its former holder. The Charles Murchison Scholarship in clinical medicine has been awarded to George Cecil Dickson, M.B., C.M.

THE HEALTH OF EDINBURGH.—The mortality of Edinburgh for the week ending with Saturday the 26th ult., was 94, and the death-rate 21 per 1,000. There were 18 deaths under 1 year, and 23 above 60, of which 7 were above 80. Diseases of the chest accounted for 29 deaths, and zymotic causes for 6, of which three were due to measles, and 1 to scarlatina. The intimations of these diseases were 42 and 25.

UNIVERSITY OF EDINBURGH BUILDINGS COMPLETION FUND.—At the meeting last week of the Society of Writers to the Signet £250 was unanimously voted as a contribution to this fund.

MEETING OF THE PROFESSION IN SCOTLAND AT THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

LAST Wednesday afternoon a meeting of members of the medical profession was held in the Hall of the Royal College of Physicians, Queen Street. The meeting was called by a circular and public advertisement. There was a large attendance of members from all parts of the country, but principally of those in and around the capital.

Dr. Balfour, President of the College of Physicians, was called to the chair. He announced that he had received a letter from Professor Fraser, in which he said that he and his

colleagues declined to attend. A letter of apology had also been received from Professor Struthers, of Aberdeen.

The Chairman said they had not a single word to say against the principles of the Bill; but with regard to the provisions there were considerable differences of opinion. After describing the constitution of the Boards which the Bill proposed to establish, Dr. Balfour remarked that the treatment of the Corporations amounted to a gratuitous insult.

Dr. Smith moved the following resolution, which was seconded by Mr. Imlach:—

“While approving generally of the objects of the Medical Amendment Bill, this meeting is of opinion that in the constitution of the Medical Board for Scotland the representation proposed to be assigned to the corporations is quite inadequate, and ought to be increased.”

He pointed out that, as the Bill at present stood, the corporations would not have their fair share of representation on the Medical Council, so that, if an appeal were made from the Board to the Council, it would practically be an appeal from the Board to the Board, and the complete control of medical education in Scotland would be transferred to the Universities. Why this should be so seemed mysterious. The talk on the other side of the border about the low standard of qualification in Scotland could only be ascribed to jealousy. It would be very hard if the fate of the Scottish corporations should be decided by the reports circulated by a few Englishmen.

Dr. Brakenridge proposed, as an addition to the original motion, the words, “Further, that by equality of representation or otherwise provision be made to ensure that one of the two members of the Medical Council elected by the Medical Board for Scotland shall be a representative of the corporations.”

Dr. Smith intimated his willingness to accept the addition, but recommended the omission of the words, “by equality of representation or otherwise.”

After a few remarks by Dr. Argyll Robertson, Dr. Charles Bell, Mr. Joseph Bell, Dr. Dickson, and Dr. Balfour,

Dr. Haldane moved, “That all candidates for the final examination of the Medical Board in Scotland be required to pay a uniform fee.” In supporting this resolution, he referred with satisfaction to Dr. Struthers' announcement that the Universities were willing that Scotland should be specially excluded from the operation of that part of the Bill to which his resolution referred. Dr. Struthers' letter was instructive, because it admitted what was an open secret before, that the Universities had been consulted before the Bill was brought before Parliament.

Dr. Keiller seconded, and the motion was carried.

Dr. Duncan moved, “That provision be made that at the final examination of the Medical Board no student shall be examined by his own teacher.”

Considerable discussion ensued on this resolution, which was eventually carried, after two amendments had been rejected, and the meeting closed with a vote of thanks to the Chairman.

THE MEETING AT THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE annual assemblies of the Fellows of the College and of the Irish Medical Association came off on Saturday and Monday last, and were occasions of very special interest. The Fellows assembled at 3 p.m., the chair being occupied by Mr. Barton, the President, and proceeded to the consideration of the annual report, the details of which, however, did not give rise to any debate. Arising out of the report, motions of much importance were presented to the Fellows. Dr. Thornley Stoker moved the proposition foreshadowed in our last issue, to the effect “that in the opinion of this College the present method of electing professors and examiners is unsatisfactory, and that the Council be recommended to seek for such alterations in the charter as shall enable these elections to be made by the vote of the entire Council, or such part of it as may

be present; not less than two-thirds of the whole number, including the President or Vice-President, to constitute a quorum for election purposes.”

The resolution was seconded by Dr. Whistler, of Bray, and was opposed by a section of the Fellows, who urged that the existing system had worked sufficiently well, and who moved as an amendment that any proposition involving a change of charter should be the subject of a notice of motion and a special meeting. It was pointed out *contra* that any motion arising out of the annual report was usually discussed without notice, and, furthermore, that the effect of remitting a subject to a special meeting was to limit its settlement to the metropolitan Fellows, inasmuch as the provincial members of the College could not be expected to come to town for such special occasion. Eventually the amendment was negatived, and the motion passed without a division by a large majority.

Dr. Jacob then moved the following resolution:—

“That this College approves of the determination evinced by the Council to ensure the *bond fides* of attendance on courses of medical study, but is of opinion that attendances purporting to be given by persons who are engaged during the usual hours of medical study in other engrossing avocations is not a *bond fide* fulfilment of the four years of study required by the General Medical Council, and therefore ought not to be recognised by this College as sufficient qualification for the Letters Testimonial of the College.”

Dr. Jacob proceeded to give the history of the establishment, in 1879, of night lectures by the Ledwich School and the Carmichael College for students who are engaged in offices and shops during the day, and the action of the Council thereon. He stated that previous to that date something more than strong suspicion had existed that persons presented themselves for the College examinations on the faith of fictitious certificates of attendance on courses of study at which it could not be pretended that they had been present, considering that they were compelled to be elsewhere all day and every day; and he adduced one case out of many in which a student, who had been engaged up to a few months previously in a bank, was passed upon the faith of a full supply of these false certificates, and immediately elected surgeon to one of the chief hospitals of the city, where he had responsible charge of the lives and health of the inmates in less than a year after his descent from the office stool. These abuses, Dr. Jacob observed, had been long suspected, but they were not acknowledged or proved until these schools publicly advertised that they were catering for such students by means of lectures delivered at night. At once the Council of the College had taken action and condemned the system, with the result that the Carmichael College immediately abandoned the practice. The Ledwich School, however, though it stated its willingness to conform to the wish of the College, and, though it had since been reminded by a second resolution of the Council, had continued the system, and had encouraged this class of students to set the College at defiance.

Dr. Jacob stated the object of his motion to be to induce the Fellows to strengthen the hands of the Council in putting down this traffic in fictitious certificates; and he urged that it was dishonest and discredit-

to follow her calling as domestic servant, on account of the difficulty in breathing, which was greatly aggravated on exertion, and became—by her own account—paroxysmal at times. There was no exophthalmos. As all the ordinary means of relieving the condition had failed, Mr. Barker removed the tumour on August the 24th, 1881. This was done with all Listerian precautions as to asepticity. A median incision, about four inches long, gave access to the tumour, which was cautiously dissected out as much as possible with blunt instruments. It proved to be the enlarged right lobe of the thyroid body, the left lobe and isthmus being normal. The latter was ligatured and divided, and the left lobe was not removed. During the dissection the vessels were tied with double ligatures, and divided between the latter. In this way seventeen silk and six catgut ligatures were used and left in the wound. Hardly any blood was lost, and the important structures around were not interfered with in the dissection. A drainage tube and gauze packing completed the operation. The next morning all the dressings were found to have slipped and become loose during the night, and salicylic wool was substituted without the spray. The wound healed almost entirely by first intention and without any inflammatory reaction, and the patient left the hospital well on September 14th. On her return from the country she was found to be quite relieved of her former trouble. The patient has been under constant observation now for nearly two years, and has had none of her former distress though she has returned to service. She has had some neuralgia in the neighbourhood of the wound at one spot which is also a little tender to the touch. Not one of the ligatures left in the wound has ever come away or shown signs of its presence, unless the neuralgia alluded to be taken as such. As the patient suffers from amenorrhœa, however, neuralgia might well be due to other causes. The author suggests the importance of collecting evidence as to the behaviour of aseptic silk in wounds of parts easily accessible to examination, seeing that as regards security and uniformity of texture most surgeons would prefer it to catgut; and if it be shown to be tolerated by the tissues as well as the latter the choice of ligatures would be simplified. This case offers in this direction several points for reflection. The author further points out that this is one of those cases which are probably far less uncommon than is supposed where small bronchoceles have produced very serious symptoms. He draws attention to other cases recorded or referred to where small tumours of the kind have produced fatal attacks of dyspnoea, and he concludes by suggesting much earlier operation for such bronchoceles than has hitherto been customary.

Mr. SYDNEY JONES described a mode of operation in these cases adopted by himself with much success, in imitation of Continental surgeons. The operation consisted in the removal simply of the isthmus of the thyroid body, ligatures being first applied on each side. In the case of a boy treated in this manner, and in which, from approximation of the mass of the trachea, introduction of a tube would have been very difficult, a complete and speedy cure was obtained, the most remarkable sequel to the operation being the atrophy of the lobes of the thyroid which followed it. Mr. Jones strongly advised that recourse should be had to this operation rather than to one involving such an amount of risk as that of removing the whole gland.

Mr. HOWARD MARSH related the history of a distressing case recently admitted into St. Bartholomew's Hospital. The patient, a man, *æt.* 21, was suffering from extreme dyspnoea, which was induced by the enlarged thyroid. Tracheotomy about the level of the isthmus was done, the trachea being found flattened antero-posteriorly, and lending difficulty to insertion of the tube. Relief was obtained by the means adopted, and subsequent operation for removal was contemplated. An attack of dyspnoea, however, carried off the patient in the night. Mr. Marsh approved the plan suggested by Mr. Sydney Jones, and thought that Mr. Barker's case would tend to convince surgeons of the necessity for immediate radical measures in these cases to relieve the dyspnoea. Respecting the silk ligature, he could add from his own experience of ligaturing the subclavian artery with that substance that most of it was retained without inconvenience. Mr. Lister was in the habit of leaving even the thick silver wires with which he sutured fractured patellæ, and with no ill consequence.

Mr. PEARCE GOULD remarked on the superiority of the operation recommended by Mr. Sydney Smith as compared

with extirpation, on account of the support given by the gland substance left behind, and thus preventing the forward dropping of the head which sometimes occurs in these cases from softening of the trachea. He asked whether such condition of the tube existed in Mr. Barker's patient; a small goitre did not usually set up such an amount of dyspnoea. Mr. Gould's experience of silk as a ligature confirmed the previous observations made on the subject.

Mr. PARKER referred to a case in which he had assisted to remove the whole thyroid gland from a child without any relief being thereby afforded to the patient. He had also under observation four women with laterally enlarged thyroids. He suggested that dyspnoea in these cases might sometimes be due less to pressure than to the mere presence of the tumour, or to interference with the inferior laryngeal nerve.

Mr. HAWARD observed that dyspnoea was usually associated with small bronchoceles, and that it ought, therefore, to be ascribed to the nature and position of the tumour. Small goitres were usually fibrous in character, and pressed tightly on the trachea and laryngeal nerves. Mr. Haward's experience led him to think dyspnoea was not often associated with lateral pressure, and in such cases the operation recommended by Mr. Jones would give relief.

Dr. LEE referred to the probable differences existing between thyroid enlargements in cretins, and in, *e.g.*, a girl of 15 or 16. Pathological differences were of great importance. He described a case in which at his recommendation a goitre treated for three or four years in vain and in various ways was reduced by repeated hot fomentations; wherefore he concluded it was unscientific to treat all cases of bronchocele on the same plan.

Mr. BARKER agreed that pressure was not essential to the production of dyspnoea, and was glad to be supported in the opinion that such condition of breathing was commonly associated with small tumours. He had found improvement follow employment of iodine internally and externally. In the case he had recorded, successive attempts at treatment were made altogether in vain: only one lobe of the gland was enlarged, and it alone was removed. The trachea was unaltered; but before the operation Dr. Poore had noticed a backward pressure on its anterior wall. The incision was purely median, and permitted the enlarged lobe to be readily shelled out. While fully agreeing with Mr. Jones that a mild form of operation was much to be preferred, he thought a much larger number of cases of the new operation must be observed before its real merits could be gauged. In his own case the structure of the growth was essentially fibrous.

DR. HABERESHON ON A CASE OF

ULCERATION AT THE PYLORUS, SITUATED AT THE VALVE, THE FLOOR OF THE ULCER BEING FORMED BY THE NECK OF THE GALL BLADDER.

It occurred in a gentleman, *æt.* 60, who began to suffer about nine months before death from pain at the stomach and vomiting; the pain was very severe in character, but most irregular in its onset, and the point of great clinical interest in the case was that "at no time during his illness did food aggravate the pain." The words were quoted from a letter of his medical attendant, Dr. Archibald. There were considerable intervals of relief, and after some weeks of comparative comfort, he was suddenly seized, after taking luncheon with his family, with intense pain in the abdomen, followed by collapse and death in about fourteen hours. The ulcer had extended through the coats into the peritoneum, and thus extravasation of the gastric contents caused fatal peritonitis. The absence of one of the most prominent symptoms of gastric ulcer—*viz.*, pain produced by food, was remarkable. It was stated that the pain of gastric ulcer ceases from varied causes, such as the healing of the ulcer, the relief of congestion from hæmorrhage, the division of the nerve from sloughing, or from the position of the patient. In the case narrated there was no evidence of hæmorrhage, nor was there any destruction of the nerve connection. The ulcer was situated at the pylorus itself, and it was doubtful at first whether it was on the duodenal or the gastric side of the valve. It was divided into two parts by a central contraction as if there had been a healing process, or as if the ulcer had been double. The base of the ulcer was formed by the neck of the gall bladder, and it was at this part that perforation had taken place. The walls of the stomach were not thickened, as if there had been pyloric obstruction. It was suggested that the situation of the ulcer had to do

with the absence of pain, and that when food was taken the pylorus contracted and the pain ceased.

Dr. MAHOMM inquired whether a symptom observed by himself in the subjects of gastric ulcer, and consisting of a ball rising up in the epigastrium, had been noticed by Dr. Habershon.

Dr. DREUIT suggested that gastric ulcers were of frequent occurrence, but were undiagnosed among hospital patients.

Dr. HADDEN asked whether the relief to pain experienced by Dr. Habershon's patient might not have been due to separation of the ulcerated surfaces following ingestion of food?

Dr. MONEY thought the ulcer might be due to lesion of trophic nerves.

Dr. HABERSHON had frequently recognised the ball phenomenon mentioned by Dr. Mahomed, and attributed it to its proper cause—*flatus*. In the particular case recorded, however, it had been absent. He was inclined to ascribe the greater number of gastric cases to nervous disturbance rather than to ulcerative changes. He thought Dr. Hadden's suggestion a very probable explanation of the facts, and had intended to imply such a theory of causation in his paper.

THE UNQUALIFIED ASSISTANT SYSTEM

AND THE

ILLEGAL SIGNING OF DEATH CERTIFICATES.

(Continued from page 468.)

THE RISE AND PROGRESS OF THE SYSTEM OF EMPLOYING ASSISTANTS.—(Continued.)

MR. GRAHAM, coroner in the County of Durham, in a letter, says: "I have felt considerable surprise at this state of things having been allowed to exist so long as it has without any action being taken in the interest of properly qualified medical men."

The employment of uncultured persons as assistants is unfair to those who are subjected to the companionship of this class of colleagues. It prevents their getting into more congenial society, and has been known in some instances to lead to the adoption of low and immoral habits. Our correspondents who have been unqualified assistants in early life invariably speak of it as their "misfortune." Several of the large employers of assistants state that the majority of young men they have had under them have been "emphatically gentlemen," and to offer grocers' or druggists' shopmen as colleagues to such worthy representatives of the profession is a gross abuse of influence and opportunity.

It is this latter class of unqualified assistants who (as may be learnt from advertisements) "would live in the kitchen or outdoors at a nominal salary," and who show their fitness for the place assigned to them sometimes by choosing a wife among their master's domestics. They commence as mere dispensers, pick up some minor surgery by looking on, and end by making themselves popular among patients of the class they belong to, and useful as general helps. A very exceptional master may now and then be found who cares to take up one of this sort and aim at making a gentleman of him; but as a rule, a surgeon has neither the leisure nor the inclination nor the inducement of interest to do so, especially as success is far from sure.

The lowering of the social position of assistants is peculiar to recent times; for the old-fashioned apprentice, whom the unqualified man replaces, was a rough school-boy often enough, but had at least the making of a gentleman in him.

5. The employment of unqualified assistants is an impediment to systematic education.

Both in London and in the provinces general practitioners are in the habit of seeking for assistance among the most industrious of the hospital students, and often apply to the deans and secretaries of the schools to recommend young men of good character. The students also find their own way to such engagements by advertisement and otherwise, in defiance of the warnings of their authorised teachers.

The unqualified assistants *in statu pupillari* are described as "neglectful of their clinical studies," backward and irregular in their clerking, and slow to profit by it. They are apparently "anxious to learn, but with minds otherwise pre-occupied." They hang about the school for years and years after the natural period of becoming qualified, and are not

unfrequently tempted away from their original ambition of being recognised practitioners. A few of the better and wiser among them slide off into other means of livelihood, the greater number remain as they are, a few defy the law, and practise for themselves without diploma. Yet even these last sometimes retain a touching attachment to their old school, displaying, "framed and glazed, the certificates of lectures" they failed to attend, and tickets of admission to the wards of which they had no time to avail themselves.

The authorities of hospital schools are entirely at one in condemning this abuse as subversive of their influence over education. Though I have sought diligently, I have not been able to find one dissentient voice to the unanimous opinion of the present teachers of schools that, "until the qualifying examination has been passed, there is no period in which a man could hold an assistantship without prejudice to his education" (Dr. Andrew, senior physician of St. Bartholomew's). "The pupils' studies are unquestionably retarded, because the time for study and reading are limited" (Dr. Phillipson, Newcastle College of Medicine). "We should strongly discourage the practice" (Dr. Wadham, Dean, St. George's). It makes the pupil's work harder, and interferes with his studies" (Dr. Scott, Warden, London Hospital). "Such men lose in proportion to the time they subtract from their hospital studies" (Dr. Taylor, Guy's). "Such men rarely go into the wards" (Dr. Morgan, Manchester School).

Dr. Leech, of Owens College, says of unqualified assistants *in statu pupillari*: "These men are the bane of a medical school. They are irregular in their habits, often idle and immoral. We have, like many other schools in the provinces, an undue proportion of these fellows, and we find them a source of unmixed evil."

The clearest justification of their coming to this conclusion is afforded by the following statistics of one year, taken from the records of St. Bartholomew's Hospital, by Dr. Norman Moore:—

"Excluding an American, who stayed only a few months, and students who entered for a single course, and for whose education the school was not responsible, there were entered in 1874—

Students for full curriculum	101
Of these there died	2
There have become qualified in the course of the eight years which have gone by	72

Of the remaining twenty-seven, eighteen got no further than the preliminary examination in arts, and have disappeared outside the scope of the present inquiry. Nine have passed some sort or part of the professional examination, but two of these have been led into more remunerative pursuits.

"The remaining seven still go on at the school, hoping ultimately to obtain some kind of qualification. They have all been unqualified assistants"; and it seems fair to conclude that it is this method of carrying on their studies which has uselessly protracted the period of education, and, at the same time, deteriorated its quality. Four of the best years of their lives have been wholly, irretrievably wasted.

The experience of other Medical Schools, such as those at Leeds, Newcastle and Bristol, Westminster, Middlesex, King's College, and St. Thomas's, is similar in its condemnation of the employment of unqualified assistants during their pupillage in private practice.

It is probably impossible to prevent this abuse by coercive measures directed against the students themselves; and, in fact, on their behalf a powerful plea is urged on philanthropic grounds. Those who take places as unqualified assistants are always poor, for all who can afford to live during their pupillage without this occupation know well how obstructive it would be to their progress and what a false economy. It is on the ground of pecuniary need that the main defence of the system rests. It offers a means by which needy youths, possibly destined to be an honour to our profession, may support the expense of their training. A case has been laid before the Committee of a dispenser, without any education but that of a national school and a chemist's shop, who was possessed with the ambition of being a medical man. He had no friends and no money. But he worked away with the aid of a fellow assistant, and got enough Latin, &c., to pass his preliminary. He remained a dispenser three years, saving every sixpence of a small salary, then got a place as assistant in a town where he could attend lectures, and passed, a few months ago, after seven or eight years of self-denial and hard work, his first professional examination. He now has taken an assistant

ship in the North of England, "until such time as he can save enough money to pay his fees for his qualification."

The training above described has been needlessly tedious, and for all those whose abilities, industry, and previous education fit them to fulfil a high destiny, ample provision is made by scholarships, exhibitions, bursaries, and paid appointments at the schools and hospitals, not to mention a few endowments at the Universities. To show how complete this provision is, take the instance of the youngest of the metropolitan schools at which a man can enter. It has no invested capital, and was built by private enterprise with money raised on debenture bonds. The annual entries have as yet rarely exceeded twenty; yet it is enabled, by the help of the staff and hospital governors, to distribute in scholarships and hospital and school appointments upwards of £840 a year by competition among those of the twenty students who are in need of it, the wealthier being usually restrained by worthy motives from competing, except for hospital appointments. This instance is selected in preference to some older and larger school with endowments, which possibly may give more, but does not so well represent the policy of the present time. Such open-handedness seems quite sufficient to aid effectually all those who are ever likely to justify the aid by aiding themselves in after-life; in fact, all poor students of superior or even average abilities. Dr. Tirard, Dean of King's College, also writes; "Of our really successful pupils, by far the larger proportion are men who from poverty have been led to work hard for scholarships in College and University. I cannot remember one, during my connection with King's College, who has taken a good position as a result of working as an unqualified assistant."

Moreover, some scholars can employ their evenings in mechanical literary work, such as translating, indexing, correcting proofs, reviewing, reporting, &c., which does not interfere with their presence in lecture-room or hospital.

Other modes of adding to their incomes might be enumerated, more open to objection perhaps than those above mentioned, but still far less grossing than the toil of an assistant.

The protraction of systematic technical education is a serious abuse. It breaks the natural connection of the elementary and practical parts by interposing an interval between them. For example, if a pupil's knowledge of anatomy has had time to grow rusty, he is less able to profit by clinical instruction. And this failure reacts also upon the retention of the science, for if he does not fully profit by his clinical instruction, he does not have the half-forgotten anatomy impressed upon his memory, as at an earlier period it might have been impressed.

If a young man is naturally dull, and has not compensated his dulness by industry, and is at the same time in narrow circumstances, it cannot be any boon to himself or others that he should be enabled to enter the medical profession. It would surely be better that, like unsuccessful barristers, artists, soldiers, sailors, and those who are rejected from the Civil Service, &c., he should embark in another and less responsible pursuit for a livelihood. Yet there is no doubt much to be learnt in the position of an assistant—much that is very valuable in after-life to a practitioner—much that cannot be taught in a hospital. It would be a firm step forwards in professional education if students had the advantage of both the two schools of mental training, without either impeding the good influence of the other.

To put this matter in various lights, the opportunity is taken of introducing the opinions of several persons, either actually engaged in education, or otherwise officially interested in the promotion of professional skill among junior practitioners. The opinions have been given in answer to letters addressed to them on the subject.

Dr. Shepherd, Dean of St. Mary's School, says: "As to the question you put to me whether it would be well to insist upon an assistantship, or a position of responsibility at a public institution before registration, it settles itself. Very few indeed from our school go without some introduction of the kind into practice. The best men get it through hospital appointments, house-surgeons, &c.; others by a partnership—happy if they don't pay for it—for a time. The University of London insists upon a six months' responsibility of hospital or workhouse patients before candidates can offer themselves for the M.B. Others go to sea."

Mr. G. A. Brown, Surgeon to Tredegar Iron Works, writes: "In order that newly-qualified men may be better fitted for their duties as curers of disease, some modified form of pupillage should be enacted or (which would perhaps be the better course) diplomas should be withheld until

evidence could be afforded that some experience in medical practice had been obtained."

Dr. Eddison, late Secretary of Leeds Medical School, writes: "I do not think it would be viewed as a hardship if an assistantship, after qualifying, were made compulsory, provided that a year's house-surgeony or house-physiciancy were admitted in place of it."

Dr. Andrew, Senior Physician to St. Bartholomew's Hospital, says: "My friends among our students often ask what they ought to do for the first year after qualifying. If they can afford it, and can trust their industry, I advise them to go abroad for a year. If they cannot do this, then to take a good assistantship."

Dr. Andrew questions the wisdom of making this advice compulsory, from a fear that there are not enough places vacant for all the candidates who pass. There probably, however, would be sufficient, if Dr. Eddison's plan of utilising the resident posts at the provincial and metropolitan hospitals were to be systematically adopted.

Mr. Morratt Baker thinks the practical knowledge to be acquired by familiarity with disease, on a less formal footing than that on which it is seen in the wards connected with a school, is very important. He suggests that it might be gained at a provincial hospital before entering at a recognised medical school.

Mr. George Johnson says: "I have no doubt that the spending a few months as an assistant after the final examination would be useful to most men. But I think it would be a hardship in many cases to make it compulsory."

Dr. Norman Moore, Warden of St. Bartholomew's College, thinks "it desirable that candidates, after qualification, should hold some resident medical appointment. If the vast opportunities of workhouses and sick asylums were properly used, this might easily be done. I think any resident appointment better than an assistantship."

"If all the possible resident appointments in London, in cases where there is no school, were tabulated, and the appointments to them apportioned numerically to the several schools in proportion to the number of students qualifying, I think it would be possible for every London student to hold such a post before registration. . . . The third summer seems to me the easiest time for attendance on midwifery."

Dr. Moore gives a sketch of a complete curriculum, concluding with "end of fourth summer, qualifying examination. Then resident appointment six months, then registration."

Dr. Tirard, King's College, London, writes: "It would certainly be desirable for candidates to spend a certain time as assistants, or as residents in town or country hospitals, before registration. The present rule, which allows a man of private means to take a practice as soon as he is qualified, is not, in my opinion, calculated to improve the standing of the profession or the welfare of the public. . . . For the majority who qualify it is well that circumstances often compel them to commence work as assistants or residents, thus forcing them to be still, to a large extent, under the guidance of seniors."

Dr. Scott, Warden of London Hospital College, writes: "Our students are strongly urged to press on and get qualified before seeking employment."

Dr. Allchin, Dean of Westminster Hospital School, approves the plan of requiring attendance for (say) six months as assistant to a general practitioner after the period of hospital study, "after the qualifying examination, but before registration. . . . It would effectually meet the present difficulty and objection to unqualified assistants. . . . The knowledge men would get by such a plan," he says, "they cannot get in an hospital, and yet it is most essential, for the want of it seriously diminishes the practical capabilities of men when starting in practice for themselves."

(To be continued.)

A NEW process for meat preserving has been discovered by Signor Pavesi, who is said to have succeeded in keeping pieces of meat for years without their flavour being impaired. During the whole time that it is required to preserve the meat, it is to be kept in a pickle consisting of water slightly acidulated with nitro-muriatic acid; and when required for use, the meat is dried at a temperature of about 60° Fahr. To avoid a slightly brown colour, the meat may be steeped in plain water before being dried.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JUNE 6, 1883.

LORD MORLEY'S COMMITTEE ON THE ARMY MEDICAL DEPARTMENT.

THIS important Report, to which we referred in our last, has now been issued, and will naturally be read with much interest by medical officers of the Army as well as those connected with them in civil life. While the medical officers have obtained general and warm praise for their care and removal of the sick and wounded from the field of battle, many serious and disagreeable facts have been brought to light in the general nursing and cooking arrangements for the proper care of the sick, very much as they were in the Crimean war, apparently the result of War Office checks and counter-checks, and the administrative deficiencies of some. Medical officers cannot regret that such facts are brought to light should the result be a final and common-sense arrangement of departmental duties in the future. The Committee believe that many of the inconveniences complained of were rather the result of the way in which the departmental system was worked than the fault of the system itself. Can this be wondered at when, as does sometimes occur, men are promoted as they come to the top of the list to be senior departmental medical officers with little or no regard to professional ability or merit beyond that of pure seniority? We assert without fear of contradiction that, as long as there is no system of non-selection of such individuals, administrative failures must follow, and with this the depreciation in the estimation of the Army and

the public of the credit and *prestige* of the medical staff. The whole gist of Lord Wolseley's evidence tends to show that in his opinion the members of the Medical Department did not assume to themselves in emergencies the full responsibilities which their position involved, and expressly stated that “if an officer in the position of a medical officer in charge of a hospital finds that the patients in his hospital are not receiving what they ought to receive in accordance with his ideas of what the sick and wounded ought to have, if it is possible for him to obtain it in any way, it is his bounden duty to do so.” To this we say—How could a medical officer, as a matter of fact, take upon himself of his own initiation to ignore and over-ride the regulations of the Service? Simply he could not if he dared, and dared not if he could. All he could do was to represent to the commanding officer the condition of things. It was for the latter to issue the required orders on the subject.

We are glad to find that individual control over a hospital is to be still vested in what in future, we hope, will always be a specially-selected medical officer, in whose prudence and common sense the Director-General may confidently rely. The regular and systematic inspection of an hospital under such an officer can only redound to his credit and that of the department. Punishment for minor offences will remain with medical officers, the more grave offences being relegated to military authority—a system which prevails in India, and appears to work well. The Quartermaster and Steward are to have their duties more clearly defined; medical officers are to exercise a personal supervision over the hospital subordinates; and the medical officer in charge is to live as near his hospital as possible; and in the larger hospitals there is to be a resident surgeon. We must say that the system which exists at some stations, apparently with the tacit sanction of principal medical officers, of allowing medical officers in charge of military hospitals to live sometimes miles away, is most detrimental to the good of the service and of the institution over which they preside. Nursing sisters are to be employed in hospitals with over one hundred beds to superintend the orderlies. Medical officers appointed to attend officers and their families are to have quarters in barracks, or reside as near the barracks as possible. The medical service of the Household Troops is to be assimilated to that of the rest of the army. Opportunity of practice with war equipment during peace is to be afforded. The evacuation principle, under which sick are constantly sent to the base, is to be checked, and each regiment is to be supplied with a pair of field panniers and surgery tent, a corporal and private of each battalion assisting the medical officer, and soldiers are to be trained for this service. Bearer companies are to be reduced to one-half their establishment, sections attached to field hospitals, and provision made for mounted bearer companies. Field hospitals are to be distributed by brigades, and the nursing staff increased to 1 to 7 patients, and all packages are to be capable of being transported on mules. Medical officers are to be held responsible for procuring the best quality of supplies procurable. Civilian cooks may be hired to superintend cooking. But it is not indicated how or where they are to be obtained on the field, or before the enemy.

We are glad to see that the Committee recommend that the examination for promotion is to be restored, a reform which will do much to raise the professional reputation of the service, especially if gentlemen who fail to keep up their professional knowledge are retired with the gratuity of their rank as in the combatant branch. The Army Hospital Corps are to be amalgamated with the Medical Department into a Royal corps, and the uniforms assimilated, a most important recommendation, which, if carried out, will do much to foster *esprit de corps*. As there appears to be a strong feeling in favour of the traditional scarlet of the old medical staff amongst medical officers, we trust the system of levelling up, and not levelling down, will be adopted, and opportunity taken of getting rid of that most antiquated and unsuitable of head-gears, the cocked hat, and the helmet substituted. We also hope no long-winded title will be adopted. Of the many suggested, Royal Surgeons, Royal Medical Staff, or Royal Medical Corps appear to be the most appropriate. We also think the opportunity should be taken of conferring on medical officers ranking as Lieutenant-Colonels of some distinctive designation, such as Senior Surgeon-Major, as proposed originally by the meeting of medical officers at Aldershot some years ago, and that measures for quickening promotion to the rank of Brigade-Surgeon will be devised. It is not an unreasonable demand upon the part of the senior qualified Surgeons-major that this rank should be reached not later than the completion of twenty-five years' service, the late War Office Committee having recommended that they should attain it at twenty-two and a-half. These reforms, with limit of tenure of administrative appointments to five years, or up to sixty years of age in cases only of exceptional merit, specially recommended by the Director-General, would undoubtedly add much to the efficiency of the Medical Department and render it still more popular.

CONCEALMENT OF DISEASE UNDER COMPULSORY NOTIFICATION.

(Continued.)

DR. CARTER, of Liverpool, writing on the effect of compulsory notification as a factor in producing concealment of disease, to a contemporary, says:—

Arguing from what seems to us to be the inevitable tendency of human nature, we believe that the exercise of the powers in question must lead to the concealment of disease; that the heads of business houses—and especially of small businesses—dreading the notification that must follow if a medical man be called in, and which may lead to their children being forcibly removed from their homes, and their business diverted into other channels, will not summon medical aid; and that, in the absence of those precautionary measures which, by the private medical practitioner's directions, are all more or less taken, disease will spread; though it may spread under other names than those of scarlet and typhus fevers. But we shall, of course, be told that to argue from the inevitable tendencies of human nature would be to show ourselves theorists, that your practical men must have facts. To facts, therefore, we will turn; and, difficult though in the nature of things it must be to prove concealment, I think that the evidence that it does exist is overwhelming.

Firstly, let me ask your consideration of a few figures,

taken from such reports of medical officers of health as have come to my hand. In Blackburn, during 1881, there were 103 notifications of scarlet fever, and 23 deaths, or 1 in every 4. In Bolton, during the fifteen months ending December 31st, 1880, there were 702 cases reported, and 112 deaths, or one in every 6.2. Or, turning to another disease: in Bolton, during the same period of fifteen months, there were 102 notifications of typhoid fever, and 23 deaths, or 1 in every 4.4. In Blackburn, during 1881, there were 281 notifications, and 68 deaths, or one in every 4.2. Now, I would ask any medical man here, whatever his practice may be—even if it be among the very lowest and poorest of the land—if he has ever known, in the most serious and fatal epidemic, such ghastly mortalities as these? The deaths from typhoid fever in Blackburn and Bolton were half as high again as at the London Fever Hospital, where, from reasons given by the late Dr. Murchison, they must always be exceptionally high. The only conclusion that seems possible from such figures as these is, either that many cases are concealed, and hence the mortality is made to appear high; or that the diseases themselves, if at all of a severe type, are fearfully fatal to the individual, where such powers as those possessed by Bolton are carried out.

But there is unexceptionable evidence of a different kind that concealment prevails. Thus, a medical officer of health for one of these towns writes: "No. 2 was a case where there were three other children in the house, but two of them were removed in the night, after I had given my certificate." From another gentleman I learned that a certain course was adopted, because parents would "wriggle out of giving notice in mild cases of scarlet fever, declaring it measles."

Again, we find that in Dublin, although no law exists to compel the physician to notify, the effect of such a law is foreshadowed by the result of a limited notification. The dispensary district medical officers are the *ex-officio* district medical officers of health and the servants of the Town Council, and, as such, they are under orders to report infectious cases to the Public Health Committee. They have done so, and the Corporation disinfectors have thereupon been sent to adopt the necessary sanitary precautions, and have been obliged to do so with every consideration for the feelings and the interests of the patient's family, inasmuch as no special powers existed to effect sanitation or isolation by force. Nevertheless, it is notorious that the result of this very limited system of notification in Dublin has been to exclude the dispensary district medical officers from practice amongst the poorer classes, and to throw the treatment of infectious cases into the hands of "club" doctors, who, not being corporate officers, are not obliged to notify, and, in fact, do not do so. The infected poor of Dublin, in many instances, even deny themselves the necessaries of life in order to be able to pay a private practitioner, rather than resort to the dispensary doctors, and the Public Health Committee of the Corporation have publicly stated this fact in their official reports. They say—

The attention of the Public Health Committee was drawn to the fact of concealment of infectious disease, and the serious consequences of neglecting to call in medical aid until the illness is of several days' duration. A child recently took ill with fever in Church Street, and no medical man was summoned to see the patient; two grown persons have since contracted fever in the same room from the child, and they are now dangerously ill, so much so that the cases could not be removed with safety in the hospital cab, but had to be conveyed on a stretcher to the Hardwicke Hospital. The last two cases were ten or eleven days ill before any medical man saw them, and if

left in the room would probably have died, as no person in the house would attend to them. The fear of incurring the censure of the landlords of tenement houses in many instances appears to be the chief reason for not seeking medical advice in time; with others the dread of removal to hospital is the motive.

We say advisedly, that in towns in which compulsory notification is the rule, concealment does take place to a very serious extent, and we ask the advocates of compulsory notification by the physician, can you prove by statistics of the number of persons who died *unattended by a qualified medical practitioner*, within towns in which notification is compulsory on the medical attendant, that the system has not caused concealment of disease, or driven the population into the arms of quacks or prescribing chemists?

The following are the regulations relating to death registration:—

a. Every registered medical practitioner in attendance on deceased must give to the person who is to give the information for registering the death a certificate of the cause.

b. The person who gives the information must deliver the certificate to the Registrar, under penalty of 40s.

c. The Registrar must state cause of death when so certified in his record; but when the deceased has been attended by no one, or by an *unqualified practitioner*, he must enter the death as "uncertified."

d. The Registrar must give, gratuitously, a certificate for burial.

e. Every such certificate must be handed to the person who buries, under penalty of 40s.

f. If no burial certificate is produced, the person who buries must at once inform the Registrar-General thereof.

g. No child's body shall be buried as still-born without special precautionary certificates.

Under the law of death registration, every information desired is available, and it is, therefore, easy for a medical officer of health to compare, day by day and year by year, the mortality from any class of disease, and to illustrate the actual results from notification by proving that zymotic deaths have been reduced in number by its agency. Moreover, an examination of the death certificates would show to what extent persons dying from infectious disease had been attended by quacks or prescribing chemists, or left without attendance; and if it appeared upon investigation that the percentage of persons who died without the ministrations of a qualified practitioner had materially increased as a sequence of the introduction of the notification system, we should then be entitled to assert that the public had been driven to resort to unqualified practitioners, who are not amenable to notification law, in order to conceal the existence of the infection, and, *ergo*, that the disease was being secretly disseminated in spite of the notification law.

We again invite medical officers of health to test the soundness of our conclusions, and the truth of the statements which we have quoted above, by showing that the proportion of persons who have died without the attendance of a physician has not increased as a sequence of compulsory notification, by which means only can they satisfy the public that wholesale concealment and dissemination of infection is not the actual outcome of the system, as it is obviously the natural result.

ICHTHYOL.

A NEW drug has been recently introduced to the notice of pharmacologists which bids fair to prove of considerable value. It has been described by G. P. Unna, of Hamburg, a well-known investigator in the domain of therapeutics, as a tarry-looking substance of the consistence of vaseline, and as possessing a peculiar odour. For reasons which will be presently stated, it has received the name of Ichthyol. It is said to be partly soluble in ether and partly in alcohol, and totally in a mixture of the two. It forms an emulsion with water, whilst with vaseline and fat it may be mixed in any proportions. It contains a considerable proportion of sulphur—about 10 per cent., which is so intimately united to the remaining constituents that it can only be separated by destruction of the ichthyol.

According to Rudolf Schroeter (*Deutsch Med. Zeit.*, 17/83), it is obtained from a bituminous mineral found in the neighbourhood of Seefeld in Tyrol. The colour of the stone from which it is obtained is a clear brown and brownish black; its percentage of bitumen varies between 10-60. In the matrix in which the stone is found are a great number of fossil imprints of fishes, and some petrified fish were even met with. In consequence of this, Professor Fritsch has concluded that the bitumen is the animal remains of ancient marine animals and fishes,—whence the name.

The bituminous stone is subjected to dry distillation in iron retorts, the result of the process being the production of a tarry like substance of a peculiarly disagreeable odour. From this after long standing a thin fluid oil is separated. After thorough purification it is treated with concentrated sulphuric acid. The superfluous sulphuric and sulphurous acids have then to be separated from the sulphate thus formed.

Unna has made numerous experiments with the substance thus prepared, both in skin and other diseases.

From a paper contributed to the *Monatsch für Pract. Dermatol.*, 11 & 12/82, and noticed in the *Deutsche Med. Zeit.* above quoted, we learn that it has been employed with good results in every form and stage of eczema, care being taken, as soon as its characteristic effects have been produced, to gradually reduce the strength of the application employed, exactly as when sulphur preparations are made use of. It must be used in a more diluted form in the case of children than is necessary in adults (10-20 per cent. in ointment for children, 40-50 in adults). He has used the following form in an obstinate case:—

Lythargyri, 10,0;
Coque c. aceti, 30,0;
Ad reman., 20,0.

Adde—

Olei olivar., adipis, ana 10,0;
Ichthyoli, 10,0.

M. Ft. ung.

In acne rosacea he saw good results from its employment, but nothing special in psoriasis.

In a later communication to the last-named paper he gives his observation on its employment in other forms of disease. Of its employment in cases of acute

are well known, and from its publication may be dated the reforms which have been productive of much advantage both to our own and foreign armies, and to the civil population as well. The paramount influence of foul air in the production of lung disease was proved to demonstration, and the art of ventilation was placed upon a secure foundation. The Barrack Hospital Committee, of which Dr. Sutherland and Captain Douglas Galton were the active members, laid down a series of regulations for the construction of barracks and hospitals, which have been followed with the utmost benefit both at home and abroad. Following this came the Indian Commission, which did for that vast dependency what the Home Commission had done for the rest of the empire. The mortality in India was found to be inordinate, and it was equally clearly traced to insanitary habits and surroundings. To recognise an evil and its cause is half way to curing it, and after a lapse of a quarter of a century we can point, not certainly to perfection, but to such an improvement as might fairly at one time have been looked upon as chimerical. The death-rate of the Army at home is only two-fifths of what it was before the Crimean war; the death-rate in India is only one-third, and the death-rate in the West Indies one-tenth.

In civil life it has recently been shown that the improvements of later times have resulted in a diminution of 2 per 1,000 in the general death-rate, and with the knowledge we now have of the causes of disease we may be sure that a general death-rate of not more than 15 per 1,000 may be confidently looked for. The remarkable immunity of soldiers and prisoners in the last epidemic shows what can be done when people can be compelled to lead fairly hygienic lives.

Although there are many names I might refer to as great writers in hygiene, abroad as well as at home, there is one which we cannot omit in a lecture like this, more especially as it is the first delivered in this museum which has been founded to his memory. Edmund Alexander Parkes did more than any other one man in this or any age to make hygiene a positive fact, a practical science, based upon not only philosophical conceptions, but actual experiments. Starting in life as an army medical officer he was able to produce during his short service in India and Burmah works upon dysentery and cholera, which will always be of the greatest value. Retiring into civil life he became eminent as a physician and teacher, and in 1855 he undertook the organisation of the hospital at Renkisi, in the Dardanelles, which was a perfect model of successful hygienic administration. Struggling with distressing and dangerous disease he continued to lead a life of intellectual activity not often accomplished by the most robust; and when, in 1860, the Army Medical School was established by Lord Herbert of Lea, Sir James Clerk had no hesitation in advising that Dr. Parkes should be secured if possible as the Professor of Hygiene. How excellent the foresight of that eminent physician was we all know, for Dr. Parkes was not only the first professor of the science in this country in point of time, but also the first in every sense of the word. The publication of his well-known "Manual of Practical Hygiene" gave us for the first time a work on the subject, which was not merely a string of opinions and surmises, but at every point brought opinion to the test of figure and experiment, where it was possible, and thus laid the foundation for a real science in the future. Similarly with his teaching he pressed upon the Government to establish practical laboratories for his pupils, where they could do for themselves as much of the experimental work as time and opportunity allowed; and he impressed upon them who studied under him the necessity of testing everything by actual investigation and bringing all statements to the proof of figures before accepting them as true. There was never probably a man of calmer and more judicial mind, a man more rigidly critical of his own work, or more kindly disposed to allow every credit to the work of others. Having known him personally for many years, during thirteen of which I was his assistant and colleague, I can bear confident testimony to

the exceeding beauty of his character, in which "sweetness and light" were never more truly displayed, and the scrupulous accuracy and care with which every investigation of his was carried out. The science of hygiene could have no purer and better founder, and its votaries no brighter and more spotless example.

URIC ACID: ITS PHYSIOLOGY AND ITS RELATION TO RENAL CALCULI AND GRAVEL. (a)

By ALFRED BARING GARROD, M.D.,
F.R.C.P., F.R.S., &c.,
Consulting Physician to King's College Hospital, London.

LECTURE I. (continued).

LET us pass on to another point in the physiology of uric acid. How can we explain the fact that, in proportion to the weight of their bodies, some animals excrete so large a quantity of such an insoluble principle as uric acid, or even as urate of ammonium, the one requiring 8,000, the other 2,400 times its weight of water at the body-temperature to dissolve it? The human subject excretes on an average in the twenty-four hours about one part of uric acid for each 120,000 parts of his weight; or, estimating the weight of a man at about ten and a-half stone, throws out about eight grains of this acid daily. This is an average arrived at from a very large number of observations, which you will find detailed in Dr. Edmund Parkes's valuable work.

In the case of the lower animals, I could find no facts on record relating to this subject, and therefore had to undertake to supply them for myself by means of observations and experiments.

In pursuit of this subject, I made observations on the relation between the daily weight of the uric acid excreted and the weight of the renal organs themselves. In the case of a lark, I found that the ratio of the weight of bird to that of kidneys was 125 : 1; in that of a linnet, 118 : 1; in that of a turkey, 172 : 1; but this latter bird was in a fattened condition, so the ratio may be somewhat misleading. Taking the lark and linnet, therefore, after calculating their daily excretion of uric acid, we find that it amounts to more than the weight of the kidneys of the same birds. Let us reflect on these facts. Is it possible to conceive, if we assume that the uric acid first exists in the blood, that the amount of this fluid passing through the renal organs could excrete as much of this principle as we have found, as a fact, to be thrown out? True, in the case of man, who excretes only one-thousandth part of the uric acid thrown out by birds, we could easily imagine this to be the process; but the more we consider the facts about birds, the more difficult does it become to believe in this explanation; and, if we go further, and hold it impossible, then the first view as to the formation of uric acid appears to me to fall to the ground.

As this question is of the utmost importance to physiology, and as its decision must necessarily be followed by weighty consequences, it is essential that nothing should be left undone which might help us to the truth. With this object before us, there arise many points which must be determined; and, first of all, we must ascertain the condition of the blood of various animals, especially with regard to the presence or absence of uric acid. I have obtained many such data from observations made during a long course of years. I have several times examined the blood of man in health, and many hundred times in various diseases; and the conclusion at which I have arrived is this: that, in absolute health, the uric acid in the blood is inappreciable by our tests, and that that fluid does not contain the one hundred thousandth part of its weight of the acid; while, in gout, the blood is very rich in this principle, as I showed in 1847; that

(a) The Lumleian Lectures for 1883. Delivered before the Royal College of Physicians of London.

bi-hourly doses of 0.5 and 0.2 grains. Somewhat similar doses produced similar effects in the pyrexia of phthisical patients. The drug was also administered hourly or bi-hourly in 0.2 grain doses in a severe case of typhoid with bloody stools. During the first days of administration, the temperature was reduced on the average scarcely 1° C., but some days it fell to 38° C. (100.2 F.), and remained at this point several hours. Later, the daily average diminution of temperature reached 2° C. If the kairine was temporarily omitted, the temperature immediately rose. Doses of 0.3 grain gave rise to rigors, collapse, and feebleness of cardiac action. Professor Drasche considers that kairine is superior to all other drugs as a promptly-acting anti-pyretic, and believes that it has a great future before it.

Clinical Society's Committee on Spina Bifida.

AN announcement was made by the President of the Clinical Society on the 25th ult., to the effect that the Committee appointed to consider and report on Spina Bifida and its Treatment had not yet concluded its labours. In consequence, therefore, its report will not be presented during the current session, which ended on Friday last; nor can it be included in the next issue of the Society's Transactions. The Committee have accumulated a very large and valuable amount of information, and are anxious to make their report as complete and exhaustive as possible. They desire to have it generally known that any gentlemen who may have cases they are willing to communicate will do so without delay, and that specimens will be especially acceptable in illustration of the subject.

Students and the Medical Bill.

ON Friday last Mr. Mundella received a deputation from the Medical Union Society in favour of the new Medical Bill. The objects of the deputation, which was introduced by Dr. Farquharson, M.P., were briefly explained by the Honorary General Secretary of the Society, Mr. Charles H. Wade, who expressed the gratitude felt towards the Government by students of medicine for the improvements promised by the Bill. It was especially urged, however, that the interests of students demanded the restoration of the "title clause," and that amendment of the Bill in this direction would be no more than an act of justice to the many young men who, by-and-by, would be influenced by the operation of the Act. In reply, Mr. Mundella said that, although he had received many deputations on the Bill, none had interested him so much as this, for he felt that in a question so deeply affecting students themselves the expression of their particular views was of value and importance. He said he was much impressed by the statement Mr. Wade had made, and held forth considerable hope that the concessions sought for might eventually be granted; certainly the matter in question had been put before him more clearly and forcibly than at any time previously. The deputation then, after thanking the Vice-President of the Council for the attention he had given to it, withdrew; and the Society may be congratulated on having very satisfactorily advanced the views of its members.

Murchison Memorial Scholarship.

THE examination for the Murchison Memorial Scholarship, held this year in Edinburgh, has resulted in its award to Mr. G. C. Dickson, M.B., C.M., House Physician at the Royal Infirmary. The examination for the scholarship was partly written and partly oral, and included examination of patients, with reports and commentaries on the cases, problems in treatment and pathology, and descriptions of specimens. The successful candidate graduated at Edinburgh University in 1882, having gained honours of the second class.

The Royal Red Cross.

A LIST has recently been published in the *Gazette* of ladies on whom the new order of the Royal Red Cross has in the first instance been bestowed by the Queen. Six members of the Royal Family head the list, and after them come five-and-twenty other recipients of the order, including Miss Florence Nightingale, Mrs. Deeble, lady superintendent at Netley, Lady Strangford, and Lady Lloyd-Lindsay. In the institution of this distinction for the women who by devotion and self-sacrifice have done incalculable good to the cause of humanity, a step has been taken which is thoroughly significant of the deep interest always taken by Her Majesty in the welfare of her people, and her appreciation of the valuable nature of the labours of those who essay to relieve the pangs of sickness and to soften the horrors of war.

The Unqualified Assistant again.

MR. EVANS, surgeon, of Pontlottyn, and his unqualified assistant, have been prosecuted, at the instance of the Registrar-General, for unlawfully and wilfully making a false certificate of the death of a child who had been attended by the assistant and had not been seen by the principal, in consequence, it was alleged, of his being suddenly called away on the day of the child's death. It was admitted that the certificate was filled up by the assistant, but that the signature was the principal's. The stipendiary, while convicting the assistant and fining him £5, declined to convict the principal on the ground that the evidence was insufficient to show that he was a party to giving and making the false certificate. He admitted that it was a reprehensible act to leave blank certificates about signed by the principal. But this did not necessarily involve the offence named in the summonses. A case for a superior court was granted.

Small-Pox in Dublin.

WE regret to learn that a case of small-pox arrived in the Liffey on Monday last on board a foreign barque. At once the Superintendent Medical Officer of Health, Dr. Cameron, took the most active steps to prevent the dissemination of the disease. The patient was at once taken to the floating hospital at Ringsend—which it was recently most foolishly proposed to sell—and the ship in which he arrived was put into strict quarantine. A special surgeon was engaged to remain on board the floating hospital night and day. Up to the period of our publication there has been no indication of a spread of the disease.

Death of Dr. Wilbur.

INFORMATION comes from America of the death of one of the most eminent and widely-known of asylum superintendents in the States, and a physician who was familiar, by name at least, to a not inconsiderable number of the profession here. Dr. H. B. Wilbur, Superintendent of the New York State Idiot Asylum at Syracuse, died on May 1st, after a service of no less than thirty years in the post left vacant by his decease. As a pioneer in the theory that care and kindness combined would suffice to effect improvements, in the condition of the unfortunate beings in his charge, Dr. Wilbur earned and has received the grateful thanks of an appreciative number of his followers, and in the work accomplished by him in the particular line he made his own especial study he has laid claim to be remembered as a benefactor of the first order. To his friends and acquaintances his loss will be a severely-felt blow, and all will regret that he has so soon, at 63 years of age, been cut off from the continuance of the labours he turned to so good account.

The Royal Medical Benevolent College.

THE annual general meeting of the Royal Medical Benevolent College was held in the Committee Room, Soho Square, on Thursday last. The treasurer occupied the chair, and the secretary read out the list of successful candidates, when it appeared that the recommendation of the committee of examination as to the most urgent and deserving cases had met with the almost unanimous approval of the body of Governors, both the vacant pensionership and Morgan annuitant being respectively elected, together with seven out of the nine foundation scholarships. The Report stated that the working of the school was now all that could be desired, many of the boys having taken honours and obtained scholarships in and out of the College, and one or more had passed directly from the school into the Universities. It is a subject of much regret to find the funds of the College are still in a languishing condition. The expenses of the institution exceed the receipts by several hundreds of pounds—a fact, we hope, which needs only to be made known to ensure a ready response from the wealthier members of the profession.

The Clinical Society of London.

JUDGED by the attendance of members at the extraordinary meeting of the Clinical Society on Friday evening, the experiment of having an extra "clearing" night was not a success. In other ways, however, it probably answered all expectations, for quite a succession of papers was read, but little discussion being indulged in. Possibly a larger gathering might have been secured had longer notice of the additional meeting been given; but as it was arranged with a view to enabling a clearance of all the papers in hand with a view to publication in the annual volume of Proceedings, no doubt all that was required was obtained. It would, however, be well for the Council of the Society to remember that discussion is a very valuable part of the programme of its meetings, and that a precedent of the kind encouraged by Friday's occurrence may, if unduly strained, result in a certain disadvantage.

Oxalurea.

WHETHER the presence of oxalate of lime crystals in the urine is a primary cause of a very unsatisfactory train of symptoms, or is itself only a symptom of a constitutional state, the conditions under which it occurs are sufficiently troublesome to deal with to demand our earnest and close attention. The cases in which it occurs usually progress very slowly towards restored health. Even the best text-books upon abnormal states of the urine pass lightly over its true significance as a symptom, and are very meagre in their directions as to treatment, &c. Dr. J. L. Bauer, of St. Louis, reports the details of a case of this nature that lately came under his notice at some length. The patient had been for many years the subject of venereal excesses, both by self abuse and sexual concourse, and had induced a highly irritable condition of the urethral membrane and prostate gland. The lips of the meatus were reddened and everted, the passage was highly sensitive, micturition was frequently painful, muco-gelatinous discharges took place from the urethra, and the urine presented mucous flakes. The prostate gland was enlarged and tender. The patient suffered from indigestion, hypochondria, general pains, constipation, and partial impotence. The patient's attention had never been drawn to the presence of a sediment in the urine until some time after coming under Dr. Bauer's notice, when he passed a large quantity of small concretions, which were found to be composed of oxalate of lime. The hyperæsthetic condition of the genital organs was overcome by the administration of a mixture, as follows:—

R Potass. acetatis, ʒiiss.;
Ext. buchu fluidi, ʒss.;
Ext. hyoscyami, gr. xij.
Syr. gentianæ, ʒj.
Aque destil. ad ʒvj.

M. A tablespoonful every third hour; and the passage daily into the urethra of a suppository containing gr. x. of iodoform and gr. v. of eucalyptol oil (Landers).

After the passage of the small calculi the patient was placed on five-drop doses of the dilute nitro-muriatic acid three times a day, to be increased to toleration; and his bladder was washed out with a solution of gtt. 1½ of pure nitric acid in ʒij. of water. The treatment was followed by perfect recovery.

OWING chiefly to the magnificent weather of the past three weeks, the mortality throughout the United Kingdom has been steadily declining, and in most of the large towns last week it was much below the average. The highest annual death-rates from diseases of the zymotic class were—From whooping-cough, 1·2 in Cardiff and 2·4 in Birkenhead; from measles, 1·9 in Liverpool and 2·1 in Newcastle-upon-Tyne; from scarlet fever, 1·8 in Derby and 1·9 in Sheffield; and from "fever," 1·2 in Hull and 1·3 in Sunderland. The 28 deaths from diphtheria included 14 in London, 5 in Glasgow, 2 in Edinburgh, and 1 in Dublin. Small-pox caused 2 deaths in Birmingham, 2 in Newcastle-upon-Tyne, and one each in London, Liverpool, Leeds, and Sunderland.

The Professorship of Practice of Medicine in the Irish College of Surgeons.

THE election of a Professor in the room of Dr. James Little, resigned, took place on last Saturday, at one o'clock. In conformity with the terms of the Charter, seven members of Council were chosen by lot to elect, and the duty fell upon Messrs. MacNamara, Tufnell, Bennett, Porter, Smyly, Denham, and Clapton. The candidates were Dr. A. W. Foot and Dr. John William Moore, Lecturers on Medicine respectively in the Ledwich School and the Carmichael College, both gentlemen being physicians to the Meath Hospital. The electors having retired and deliberated, announced that they had elected Dr. Foot.

The new Professor is a Licentiate of the College of Surgeons of 1862, a Fellow of the College of Physicians, and an M.D. and Diplomate in State Medicine of the University of Dublin. He enjoys a very high character as a teacher.

Modern Circumcision.

AN interesting illustration of the progress and direction of modern thought is given in an official circular of instructions, issued under date of January 10th, 1883, to the Israelitish communities of Baden. It sets forth that the only persons who are to be permitted for the future to perform the rite of circumcision shall be such as shall be authorised by the Jewish Supreme Council. The persons thus authorised are to observe accurately a series of directions, from which we notice the following:—The knife employed in the operation must be freshly polished for each circumcision, and the forceps used properly purified. 6. The quadrangular pillow employed, as well as the sausage-shaped ring, must be frequently renewed, and, before every circumcision, covered with new gutta-percha tissue or new sarsenet. 7. The operator immediately before the operation must carefully wash his hands with soap, and cleanse the nails with a good hair brush, taking peculiar care that no dirt be allowed to remain under the nails, more especially under those of the thumbs. The hands must in addition be washed in a 5 per cent. solution of carbolic acid. The operator is no longer to suck the wound nor irrigate it with wine ejected out of the mouth. Instead of this the blood is to be removed by gently wiping the wound with pledgets of purified lint boracic lint dipped in wine. The wound is to be closed by being enveloped in a strip of 10 per cent. boracic lint. The further removal of fluids and blood clots is only to be effected by means of a new sponge previously soaked in a 5 per cent. carbolic solution or by salicylised lint. A medical man must be immediately called in if hæmorrhage be considerable and cannot be at once stopped, or if it be from an artery. Such authorised persons are forbidden to perform the rite if suffering from any infectious disease, and until complete recovery has taken place. Every operator must send in to the district Rabbi once in six months a list of the persons on whom the rite has been performed. Such list to give the name, to state whether the circumcision was performed on the eighth day, if not, why not; whether any accident occurred during the performance, particu-

larly with regard to excessive hæmorrhage; results, &c. Any neglect in carrying out these instructions is punishable by law, and also entails the withdrawal of the certificate of authorisation of the offender if the Supreme Council decide upon such a step being desirable. We see in this circular the far reaching effects of modern science in thus modifying in accordance with its teachings the most ancient religious rite of which we have any knowledge, and of the spirit of progress that pervades a religious community, generally considered to be very conservative in all that pertains to its ritual.

It is decided that the *conversazione* to be given by the Royal College of Physicians shall take place at the College on Wednesday, July 4, at nine o'clock.

THE Harveian Oration of the Royal College of Physicians will be delivered at the College by Dr. Habershon on the afternoon of Wednesday, June 27, at four o'clock.

WE are requested by the treasurer of the British Medical Benevolent Fund to state that he has received a second donation of £100 from Dr. James George Beaney, of Melbourne, towards the funds of the Society.

A NOVEL method of collecting funds for a hospital was adopted last Sunday week by the Friendly Societies of Kentish and Camden Towns, who paraded the principal streets in procession, and by the aid of collecting boxes obtained the handsome sum of £150 in aid of the new wing recently added to the North-West London Hospital.

THE annual dinner of the Army Medical Department took place, at the Inns of Court Hotel, on May 25th. One hundred and eleven officers—past and present—sat down, under the presidency of the Director-General, T. Crawford, M.D.; the vice-chair was occupied by Inspector-General R. Lawson (retired). The guests were Sir J. W. Reid, K.C.B., Director-General of the Navy; and Sir Joseph Fayrer, K.C.S.I., of the Indian Medical Service.

It has been decided henceforth, the Cairo correspondent of the *Standard* says, to use Mount Troodos, in Cyprus, as a health station for the troops serving in Egypt. This station, which is distant only 30 hours by sea from Alexandria, presents many advantages to invalids, and is specially suited to the wives and families of officers, its nearness to Egypt representing a great saving of time and expense.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 30, Bombay 29, Madras 34, Paris 28, Geneva 41, Brussels 22, Amsterdam 25, Rotterdam 26, The Hague 23, Copenhagen 23, Stockholm 25, Christiania 19, St. Petersburg 40, Berlin 27, Hamburg 29, Dresden 30, Breslau 36, Munich 34, Vienna 35, Prague 47, Trieste 24, Rome 28, Venice 21, Lisbon 29, Philadelphia 22, Baltimore 19.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

THE SCOTCH CORPORATIONS AND THE UNIVERSITIES.—At present a severe contest is going on between the Corporations and the Universities, and as usual much may be said on both sides. The Corporations claim that they existed before the Universities, and were the first to institute an examination in arts, condemned especially by the University of Edinburgh. This statement is perfectly true, especially on the part of the College of Surgeons. The Universities claim that they are *bona fide* teaching bodies: this is only partly true. The Edinburgh Corporations have always, though in a somewhat half-hearted way, fostered medical education. They have required the teachers of the medical school to pass an examination in the branch of study proposed to be taught, which examination is recognised by the Universities. For the professors in the University no such test is required, the only requirement for a professorship being the amount of interest he can procure, the methods of obtaining this being in many cases not the most creditable to the parties concerned. The Universities charge the Corporations with selling their diplomas. This is a dangerous weapon in the hands of both parties. Readers of old plays not well known to the present generation will have read of a certain Dr. Pangloss who obtained a doctorate from an ancient northern university, and the memories of St. Andrews have not quite died out. There is, however, one charge which the Corporations can bring against the Universities which is irrefutable, and that is, that the Universities, by allowing their teachers to examine their own pupils, have permitted a species of extortion which in some cases is simply disgraceful. The system has been disastrous in more ways than one. It has stamped men with high-sounding titles who were simply crammed with the crotchets of their teachers, and whose mental growth was dwarfed by the very institutions whose duty it was to enlarge the understandings of their *alumni*. The system has sapped the manliness from the students by turning them into cringing hypocrites and servile imitators. The Corporations, on the other hand, whatever may have been the fallings in their examinations, have always allowed a wider field for their candidates, and the candidate and examiner have met on a broader platform. The abuses just mentioned could easily be met by taking the examining power out of the hands of both parties—that is, as far as the minimum State examination is concerned.

THE FUTURE OF THE EXTRA-MURAL SCHOOL, EDINBURGH.—If the Medical Amendment Bill becomes law, the outlook of the Extra-Mural School is dark enough, and medical education in Scotland will suffer a fatal blow. To make this statement clear, we will mention the facts of the case as they will stand if the Bill passes in its present form. The final examination in medicine, surgery, and midwifery is alone to be conducted by the new Board. The examinations in the primary subjects are to be conducted by the Corporations and Universities, to which latter the great bulk of the students will, as now, be attached. The professors enjoying their right of examining will fill their classes by demanding a knowledge of their crotchets, the result being that the Extra-Mural teachers will have to close their lecture-rooms, and the whole monopoly of teaching will be thrown into the hands of the Universities. There being no rivalry, the teaching will soon degenerate. Those who have at heart the welfare of medical education in this country will take care lest the evil we have pointed out become an established fact.

A COUNTERBLAST FOR SIR WILFRID.—In the course of his examination before the Crofters' Commission at South Uist, Dr. Donald Black, the parochial medical officer, said that the public health was pretty good, but in spring and winter there were numerous cases of chest diseases due to the reduced state of the body. Pulmonary complaints and chronic rheumatism were common ailments; scrofulous affections were not common. The idea that consumption was much more rare in the island formerly than it was now was, he believed, owing to the fact that in former times they were less able to diagnose properly. There was a considerable liability to fevers, such as typhus, owing to the close proximity of the houses to cattle, and the bad drainage. The children were, upon the whole, fairly clothed. "*Giving tea to the children was quite prevalent, and, in his opinion, injurious.*" Milk, of course, was the best thing they could get, but in the event of their not being able to get it, *he would recommend a cheap beer*, beginning with children at from one to two years of age.

ANTI-VIVISECTION CONFERENCE IN EDINBURGH.—At a thinly-attended conference of those opposed to vivisection, held in Edinburgh on the 26th ult., a resolution in which the conference viewed with alarm the statement by the Home Secretary, that he had accepted the assistance of the "Association for the Advancement of Medicine by Research" in carrying out the duties imposed on him by the Vivisection Act, 1876, and disputed the statement that under the Act demonstrations in illustration of lectures were prohibited, was adopted.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 26th ult., were at the rate of 33 per 1,000 per annum, against 35 in the preceding week, and 28, 22, and 27 in the corresponding periods of 1882, 1881 and 1880.

UNIVERSITY OF EDINBURGH.—The following scholarships have been awarded:—The three Vans Dunlop Scholarships in the Faculty of Medicine were awarded to—one in natural history, including geology and botany, to George L. Gulland, M.A., B.Sc.; one in anatomy, physiology, materia medica, and pathology, of £100 a year, tenable for three years, to Fourness H. Simmons; and one in the same subjects to M. S. Altounian, which had been resigned by its former holder. The Charles Murchison Scholarship in clinical medicine has been awarded to George Cecil Dickson, M.B., C.M.

THE HEALTH OF EDINBURGH.—The mortality of Edinburgh for the week ending with Saturday the 26th ult., was 94, and the death-rate 21 per 1,000. There were 18 deaths under 1 year, and 23 above 60, of which 7 were above 80. Diseases of the chest accounted for 29 deaths, and zymotic causes for 6, of which three were due to measles, and 1 to scarlatina. The intimations of these diseases were 42 and 25.

UNIVERSITY OF EDINBURGH BUILDINGS COMPLETION FUND.—At the meeting last week of the Society of Writers to the Signet £250 was unanimously voted as a contribution to this fund.

MEETING OF THE PROFESSION IN SCOTLAND AT THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

LAST Wednesday afternoon a meeting of members of the medical profession was held in the Hall of the Royal College of Physicians, Queen Street. The meeting was called by a circular and public advertisement. There was a large attendance of members from all parts of the country, but principally of those in and around the capital.

Dr. Balfour, President of the College of Physicians, was called to the chair. He announced that he had received a letter from Professor Fraser, in which he said that he and his

the clonic contractions. A safe and permanent contraction following the expulsion of the secondaries might in this way be usually secured in from ten to twenty minutes. The chief error at present consisted in mistaking constant irritation for support of the uterus.

The PRESIDENT said the paper raised several questions of deep interest, as to the time at which the placenta should be removed, the danger on the one hand of being too precipitate, and on the other of leaving in the placenta too long; how far hæmorrhage was sometimes induced by a too speedy removal and at other times by leaving the placenta too long in the uterus, and also as to the danger of leaving in portions of the membranes.

Dr. HARLEY objected altogether to premature pressure over the fundus of the uterus for the purpose of pressing off the placenta. He also objected to exercising pressure on the cord at any period.

Dr. W. J. SMYLY stated that in the Strasbourg Hospital, where the patients were as a rule left to Nature during the third stage of labour, it had been observed that the placenta was most frequently expelled in the manner described by Schultze. He believed that Credé's method of exciting the uterus to contraction had been confounded with the hasty expulsion of the placenta. Credé himself never advocated the immediate expression of the placenta, but rather the immediate excitation of the uterus by irritation and friction through the abdominal walls, and then usually with the third or fourth contraction the expression of the afterbirth. The immediate expression of the placenta was very liable to be followed by the retention of the membranes and post-partum hæmorrhage.

Dr. MACAN said that since the time of Hippocrates there had been ebbs and flows of opinion as to whether expulsion of the placenta should be left entirely to Nature, or should be immediately effected by the accoucheur, either by passing the hand into the uterus, as the older authorities recommended, or by the more modern treatment of expression. Hence he thought that a happy mean between these two methods was probably the best way, for if the uterus was well contracted there need be no fear of hæmorrhage, and therefore no cause for hurry, while if the uterus was relaxed with hæmorrhage the removal of the placenta tended certainly to increase the hæmorrhage by removing all pressure from the mouths of the uterine sinuses, unless the means used to remove it at the same time caused the uterus to contract. The great advantage claimed at the present day by the adherents of the plan of leaving the whole process to Nature was that a much larger proportion of the decidua came away with the placenta than when the placenta was immediately removed. When two such authors as Dr. Matthews Duncan and Professor Schultze differed as to the mechanism of the separation and expulsion of the placenta, it was pretty certain that there was more than one way, and that both their views were probably right. If they adopted the expression plan, which might, he thought, be called "the Dublin Method," they should be careful not to allow the placenta to be suddenly expelled on to the bed, for a sudden strain was thus put on the membranes, and a portion might easily be torn off and left behind in the uterus. This had been looked on as a very serious accident, but he was inclined to think that the mere presence of a portion of the membranes in the uterus for some days after delivery could not be looked on as dangerous unless air had been allowed to enter and set up decomposition. He also thought that it was very often during the efforts made to remove a piece of retained membrane that the air was caused to enter the uterus. He had often seen a piece of the membrane expelled some days after the delivery without being accompanied with the slightest fever, or giving rise to the least fever; indeed, it seemed to him probable that in hospital practice at least the danger from retention of a portion of the membrane was less than the danger of infection from the hands of the operator in his efforts to remove it. He always waited a quarter of an hour before attempting to press off the placenta, and considered that light friction over the fundus with the tips of the fingers was a much more powerful method of inducing contraction than merely holding the fundus in the hands.

Dr. NEVILLE having also spoken,

Dr. R. HENRY briefly replied; and

The Section adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE INTERNATIONAL MEDICAL CONGRESS.

At the usual monthly meeting of this Society, held on Friday, the 4th inst., Dr. E. HART VIXER in the Chair, Dr. THUDICHUM, who had attended the recent International Medical Congress at Wiesbaden, stated that that body had met with a view of advancing medicine to the level of the natural sciences. The question of the extermination of infectious disease was fully discussed, but no new theory of particular value was advanced. Naturally, in a city where there were continual experiments in chemistry on a large scale—in the chemical factory in that city thirty professors confined their attention to theoretical chemistry—great attention was paid to the action of medicines on the human system. It was acknowledged that the chemistry of the body was badly understood, and that definite results from the action of medicinal agents could not be looked for at present. A clinical professor from Berlin gave an interesting account of the result in 40 cases of the treatment of tuberculosis with corrosive bichloride of mercury by means of the syringe, but although benefit was said to have been derived by some of the patients, he regarded phthisis as being left where it was, and could not recommend its adoption. In some of the German hospitals he found that tubercular disease of the lungs was being treated surgically. A rib was excised, and with every antiseptic precaution the diseased portion removed. Patients so treated had recovered in some cases. He hoped to continue his remarks at a future meeting.

Dr. BRUCE CLARKE read a paper on

THE PRACTICE OF THE BONESSETTER,

In which, after briefly alluding to the variety of cases that found their way to the bonesetter, and derived benefit from his treatment, he alluded to the pathology of stiff joints, and showed from observations of severe cases which he had been able to examine after removal of the limb, that adhesions were usually found outside joints and tendon sheaths, and were due to contractions of the limb. Adhesions were rarely found inside the tendon sheaths or joints. When they were the disease was far more serious, and rarely yielded to treatment. In cases of old stiff joints, the skin, and probably the subcutaneous tissues, became weakened and atrophied by disease, and were so rendered more liable to injury—in proof of which he cited several examples of tearing and laceration of the skin without the employment of undue violence. The usual history of the class of cases that came under the hands of the bonesetter was this: The patient met with an injury resulting in a dislocation or fracture, or perhaps, only a severe bruise or sprain. He readily recovered up to a certain point, but when an inflammation had subsided, there remained a stiffness accompanied by pain on movement. In other cases there were periodical attacks of synovitis. The treatment in all such cases was active movement with or without chloroform, which was usually accompanied by a click or crack, ascribed by the bonesetter to the replacement of the bone, but which was due to the freeing of the corrective tissue bands. In slight cases one violent flexion might cure the trouble of months. In severe cases the treatment would be measured by months rather than minutes. The pathology of such cases was as well marked as that of iritis; when there was the advantage of seeing the adhesions not only form, but rupture and disappear. He expressed his obligation to Mr. Wharton Hood's lecture, which had induced him to study this subject. The difficulty with these cases was the selection of time for rupture. Signs of inflammation were their guide in that matter. Rest should be relegated to its proper position in surgery, and should not be kept up when it increased instead of abating the patient's troubles.

Mr. KERTLEY thought Mr. Clarke could hardly have chosen a more interesting subject. Undoubtedly, the bonesetter frequently earned great credit by the manipulations which broke down adhesions outside a joint, and at the same time removed the cause of inflammation; for in these cases there was no contraction of membrane. Where there was an osseous fibroid band, the case was of strumous origin—it was due to the presence of organisms. In such cases the joints became adhered, and there was great danger from the rough usage of the bonesetter. In the treatment of such joints he had put on ice for several days with great advantage, and had repeatedly put them straight. When once

convalescent, a joint rarely again became strumous. There was much bewilderment with regard to the value of rest, which was only a negative factor. It was the natural tendency of a colony of germs to die as the joint became healthy.

Dr. ALDERSON related the case of a knee which became enlarged fourteen days after confinement, but without pain. He called on Dr. Hewitt, who ordered rest, the knee to be rubbed with salad oil. He also used Scott's dressing. Subsequently, at Brighton, a seaweed poultice was used. The treatment was successful. He had also known an enlarged ankle which was caused by the use of lotion and embrocation, proving that there was no fracture.

Dr. ALLDEN OWLES had seen several cases confirmatory of the opinions advanced in the paper. One was a shoulder, the manipulation of which caused agony to the patient, but in which motion was regained. Another, regarded at first as a strumous joint was eventually cured by somewhat violent manipulation.

Dr. VINEY referred to the case of an officer of the 60th regiment, who sustained a compound fracture below the knee whilst playing at football in India. The bones were set by some naval surgeons who were watching the game, but in consequence of the leg being deformed the adhesions were broken, and the limb was re-set. The ankle then remained fixed, and the patient's health suffered. However, Mr. Erichsen was called in, he broke the adhesions, and the patient recovered so thoroughly that he was enabled to rejoin his battalion in the Transvaal.

Dr. BRUCE CLARK, in reply, pointed out the necessity of distinguishing chronic cases, as such were usually made worse by movement.

THE UNQUALIFIED ASSISTANT SYSTEM AND THE ILLEGAL SIGNING OF DEATH CERTIFICATES.

(Continued from page 492.)

THE RISE AND PROGRESS OF THE SYSTEM OF EMPLOYING ASSISTANTS.—(Continued.)

In his introductory lecture at St. Thomas's Hospital in 1873, Dr. J. Harley suggested the attaching to each hospital an out-patient department, which might take charge of patients too ill to come out, and precluded by the nature of the disease, or other circumstances, from admission to the wards, and who might be seen at home by students *in their last year, after lectures, &c., had been fully attended.* Superintendence by the seniors of the staff is implied. (a)

This is quoted not from its having been taken into separate consideration, but as showing how important this part of training is considered by those interested in medical schools.

Dr. Theodore Acland, M.B. Oxon, writes: "There seems to be no doubt that much valuable experience might be gained by those who are about to enter practice, if they were compelled to hold a resident appointment in some hospital recognised by the examining boards; or, failing this, to occupy the post of assistant to some registered practitioner, after having obtained a diploma, but before being allowed to place their names on the Register."

Mr. Marcus Beck, in his introductory address at University College Hospital this year, recommending his pupils to study with a dispensing practitioner as a sequel to hospital work, thinks that "six months of such experience would be quite sufficient."

Dr. Redwood, of Rhymney, county Durham, writes: "It would undoubtedly be a great boon to medical men, and a decided benefit to themselves, if candidates were required, after passing the qualifying examination and before being registered, to act as assistants for six months at least. They would then not only be better able to prescribe, attend casualties, &c., but would have some practical knowledge of, and be more handy at dispensing, besides being more neat and methodical in their work altogether. I have found some assistants very deficient in these respects."

Dr. Leech, of Owens College, is of opinion that "education

for general practice is not complete unless a man has worked under a general practitioner."

There seems to be no doubt in the minds of teachers, pupils, and practitioners, who communicate their views, that in addition to the systematic school teaching, a young man should go through a certain probation, involving partial charge of patients, before he enters on independent practice. It would be very desirable to give to all that which the wisest teachers recommend to their most industrious friends, who in point of fact least of all need it. If it is of use to the cultured and intelligent, of how much more use might it be to the average student, of how much more to those whom John Milton calls "the stocks and stubs" of the school, who are trembling on the verge of becoming burdensome or profitable to the community, and for whom the scale inclines one way or the other, according to the mode in which they pass the first few months after the final examination. What appears to be desired is something equivalent to the "title for orders" in the English Church; that is to say, service as a curate for a certain time after examination, but before full ordination to professional work, which service is required of every secular priest. The plan is found to operate satisfactorily, and, although troublesome to some candidates, has not been complained of as a hardship.

There really is no valid reason against requiring a candidate for registration to spend at least six months after final examination, but before being registered, as assistant to a registered practitioner recognised by an examining board, or in some equivalent public post where he would be under supervision.

And the suggestion that this end should be obtained by the licensing body keeping the issue of the diploma in abeyance till the assistantship shall have been served, is well worthy of consideration.

The period of assistantship before registration would be a good time for that attendance upon pregnant women which is required of candidates by nearly all the licensing bodies in the kingdom.

It is obvious that hospital students, who before their final examination give obstetric aid, do so as unqualified assistants. Their employment in that capacity is open to objection, and occasionally leads to serious evils, and to dissatisfaction among the tens of thousands (a) annually trusted in the hands of these students. It is also an inconvenience, to say the least, to the school staffs; and is found to be "the portion of the course of instruction which is, practically, by far the most difficult to carry out," as Dr. Arthur Farre informed the Council in 1869. (b)

Nevertheless, the greatest objection to this abuse in the eyes of a Council of Education will probably be that it so completely occupies the body and the mind of the student as to be a serious interruption to other engagements. Dr. Norman Moore finds at St. Bartholomew's that attendance on women in labour "makes most men for the time quite unfit for any other occupation."

The question naturally arises whether enforced attendance on women during their confinements, or even in labour, is, as a means of gynecological education, worth the sacrifice it entails. It would hardly appear to be so; for as a matter of fact, training for midwifery with charge of women and infants does not so readily fit a man to show himself competent for practice as training for medicine without charge of patients. At the London College of Physicians, there have been rejected from the examination for licence during twenty years, 367; on the score of medicine alone, 62; on the score of midwifery alone, 109; on the score of both together, 136; leaving a balance of 75 per cent. against the midwifery. Previous to this examination, attendance on twenty labours is required.

In Scotland, where six is the number required, there does not appear to have been observed any notable difference between the numbers of rejections on the score of midwifery and of other subjects. In fact, at Edinburgh, according to the report of Dr. Simpson, none have failed in midwifery who have not failed in other subjects also. It is noticed, however, by a late examiner at Glasgow, that candidates who have come up chiefly from English provincial schools (which are largely frequented by unqualified assistants employed in attending pregnant women and their offspring) were "shockingly ignorant of midwifery."

(a) Germans call this course of study "Poliklinik"; probably some such term as "Home-wards" or "Home-visiting" would be more agreeable to English ears. It would of course rank as an assistantship.

(b) If an average of twenty labours is required for each candidate for diploma, the 1000 who pass the examination have had 40,000 labours and women in their charge.

(c) See Report of the Committee on Professional Education, p. 27.

That there exists an unexpressed want of confidence in the desirability of attempting to instruct pupils by employing them prematurely in work, is shown by the great diversity in the numbers of accouchements required at the several examining boards to have been conducted by the candidate. At the King's and Queen's College of Physicians, and at the College of Surgeons of Dublin, it is thirty; at the College of Physicians in London, it is twenty; at the Queen's University, Ireland, it is ten; at Edinburgh, Aberdeen, and Glasgow, it is six; at the German Students' Examination it is four; at the University of Oxford it is none.

Independently of all evidence derived from experience, it might have been expected that, during the period devoted to the acquisition of knowledge, to call upon the pupil to exercise that knowledge as if it were complete, would check its further development. It stunts the growth of the mind, just as too early toil stunts the growth of the body, and leads a young man to think his education accomplished, and that he is already furnished with all the requisites for practical life.

There is not the same want of confidence in the other means of education, such as definite courses of lectures, clinical instruction, and preliminary studies, the quantity of which called for by each licensing body varies very little indeed.

It must be always remembered that the taking charge of these patients of the obstetric department is enforced solely as a *means of education*; for it is not supervised by an examiner, which must be done where it is made a *test* of efficiency, as in the German Staats-examen. In the last-named examination the "necessary operations," in one selected instance, have to be "performed under the eye of an examiner," and a written report of the progress of the case for nine days handed in for inspection. (a)

(To be continued.)

Special.

THE NATIONAL HEALTH SOCIETY'S EXHIBITION.

POPULARISATION of reforming habits has by common consent become a legitimate part of society work, and not a few of modern associations have been founded with a view to carrying out reforms having for their object the general welfare of the people: Such unselfish labour is eminently praiseworthy, and deserves to receive every kind of encouragement that can properly be given to it; for, although a good many hobbies are ridden, at times to a desperate extent even, by more enthusiastic supporters of such societies, still the aggregate good they accomplish suffices to bury far out of sight such harmless indiscretions as are sometimes committed by too zealous reformers. Especially may this be said in connection with the National Health Society, which, although it is sometimes committed to seeming absurdity by its members, is nevertheless slowly accomplishing valuable work by popularising at least the consideration of domestic and personal hygiene. Little soever as it may be, every little done in this direction is so much absolute gain in a national sense, that the amount of interest taken in the exhibition of hygienic dress, sanitary appliances, &c., now on view at Humphrey's Hall, Knightsbridge, is an excellent indication of advancing opinion on subjects of importance to the home and the individual, both hitherto too lightly regarded.

The Exhibition is not an extensive one, but it is sufficiently representative to be well worthy a visit of inspection. Prominence is of course given to "the dress of the future," several stalls being set apart for the display of garments cut in the approved form advocated by Lady Harberton and her disciples. Here and there, too, in the building may be seen living wearers of the much-derided costume, and certainly as a mere matter of elegance and beauty, the unreformed eye finds difficulty in admitting the superiority of appearance possessed by the hygienic costume, however ready the observer may be to admit its

unquestionably greater healthfulness. Possibly, by-and-by, when the new dress is universally or very generally worn, the absence of contrast will lead to the evolution of more accurate notions of the beautiful in the masculine mind; and then in all probability we shall unanimously despise our own distempered judgments, which lead us now to look more favourably on the shapely dress than on the shapeless costume which hangs on those who exhibit it in use at the Exhibition.

A prominent position facing the entrance way is occupied by a stall filled with a large collection, of drugs, &c., exhibited by the well-known firm of Burroughs, Wellcome, & Co. Among the novelties to be found on this stand (Block B.), the most recently introduced improvements in pharmacy are "the Burroughs elixoids." These comprise an elegant and agreeable series of liquid medicines in the production of which, success has been carried to a very high degree of perfection; the process of preparation having effectually disguised the taste of a number of drugs, against the administration of which their unpalatableness is often a serious objection. Bromides of potassium and sodium, colisaya bark, iodide of potassium, and biniodide of mercury, and a number of other remedies and combinations are offered in this improved shape, which is unquestionably a very great advance on the older forms. Messrs. Burroughs & Wellcome show also a most deliciously fragrant perfume, to which the appropriate name of "edenia" has been given, and which, for purity and exquisite odour, is altogether matchless. It has a most refreshing effect moreover, and for the use of delicate invalids it is likely to become a favourite scent. Compressed tablets of potassium permanganate, each containing two grains, have been added to the familiar "Wyeth" series, and will be found of much service for general internal use, and in many affections of the mouth and teeth; this form of the drug, moreover, admits of ready and convenient employment under any circumstances. "Hazeline, Florida Water," MacKesson & Robbins' capsuled pills, and other well-known specialities for which the house of Burroughs & Wellcome is famous, are also shown, but need not be further mentioned here.

At the opposite end of the hall to that occupied by Messrs. Burroughs and Wellcome's stall will be found that of Messrs. P. and P. W. Squire (No. 53), who show several novelties that are worthy of more than passing attention. Among these a recently added improvement to the well-known medicine chests manufactured by this firm calls for especial notice. This ingenious arrangement consists in a patent spring lid, by means of which the stoppers of bottles contained in the case are, when it is closed, kept securely in place, thus obviating the necessity of fastening them by means of a cover or cap. Such a contrivance has long been a desideratum, and the provision of it will be a most useful addition to many a hard-working practitioner; for the invention can be applied to cases of any size, and for all purposes. Messrs. Squire have also introduced a new malt extract, termed by them "superdiastatic," and which, it is claimed, possesses unusual digestive powers. It is certainly a most pleasant and palatable form of extract, and will doubtless be very favourably received by the profession. Among the elegant preparations exhibited on the stall none are more interesting than those in which the antiseptic agents, eucalyptics and thymol are presented; and particular mention must be made of the toilet requisites into the composition of which these valuable agents enter. The soap tablets are very agreeable and healthful. Several forms of lozenges also are shown, among them those containing eucalyptics; and a cheap but efficient respirator made for hospital use deserves notice.

So much favourable notice has already been given to the Maltine Manufacturing Company's speciality, and the preparation is so universally recognised as an invaluable therapeutic agent, that little more than mention of the fact that it is shown in the exhibition need be said concerning it. We must, however, refer to another important

(a) Belgel and Bruce. Report on Prof. Education. 1889.

article introduced by the same firm, and which, as "Reed and Carnrick's Beef Peptonoids," have within a short time won the unanimous approval of those who have employed them. These peptonoids consist of concentrated powdered beef extract, *partially digested*, and in combination with gluten in equal amount. For economy and palatableness this preparation is unrivalled, while also it is a valuable clinical assistant. We hope soon to publish reports of the experience gained after extended trial of the peptonoids in cases of disease.

Messrs. Allen and Hanburys' stall contains samples of most of the "well-known A. & H." preparations, among them the "tasteless" castor oil, "perfected" cod-liver oil, &c., by the introduction of which they have achieved a well-deserved reputation. The "A. & H." malt extract and farinaceous foods also demand attention.

An important collection of the preparations of natural digestive ferments with which Mr. Bengler's name will always be inseparably connected is shown on Stand 7. The already widely known and appreciated "liquor pancreaticus," and "liquor pepticus," with the "peptonised beef jelly," and "self digestive food," are all exhibited; and it is highly probable that every medical man who visits the exhibition will mentally reflect on the advantages derived in his own practice from the admirable and effective assistance lent to his efforts by the results of Mr. Bengler's long-continued labours. Certain it is that few modern improvements in pharmacy have done so much as Bengler's preparations to assist the physician in his treatment of the sick; and it is in the highest degree satisfactory to learn that steady progress is being made, not only in the direction of perfecting these invaluable remedial agents, but also in the extent to which they are appreciated and employed.

In the way of creature comforts pure and simple the exhibition is fairly well supplied, among the evidences that hygienic principles extend even to material blessings being the array of wines and other liquors of the kind that cheer and even inebriate if too freely indulged in. In this respect, however, the samples exhibited by the Australian Wine Company (Stand 28) might well tempt the most careful to somewhat unusual "tasting;" for some of the brands introduced from the Antipodes compare even more than favourably with European wines of similar class. It is easy to comprehend, after once making trial of them, why public taste is rapidly approving these newly-introduced vintages, for they possess a wholesomeness and agreeableness which can be the accompaniment of purity and quality alone. Added to their excellent qualities the comparatively low price at which the wines of Australia are put on the market must inevitably tend to bring them very generally in demand among those who regard the properties rather than the source of their wines. The "Muscat" sold by the Australian Wine Company at 42s., and the Hermitage at 36s., a dozen is, altogether apart from its price, one of the choicest liquors we have ever tasted; and many of the cheaper white Australian wines are infinitely superior to much of the expensively-rated produce of Continental vineyards sent to the English market.

Mr. James L. Denman shows a selection of pure Greek wines, which also deserve the careful attention of connoisseurs. Reasonable in price, choice in flavour, and of guaranteed purity, there is every reason why these, like the Australian growths just noticed, should be admitted to replace the deteriorated vintages of France and Germany. We would especially recommend trial to be made of the "St. Elie" (white), "Como" (red), "Noussa" (red), Greek wines.

The exhibition includes a large number of other objects to which we should, if space permitted, willingly draw attention. "Mellin's Infants' Food," "Feltos's Lime Juice," "Maignen's Filtre Rapide," "Cleaver's Terebent Preparations and Soaps," improved cowls, water-closets, ventilators, &c., &c., all deserve attention, and the visitor will do well to spend some time in examining them.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 13, 1883.

LORD MORLEY'S COMMITTEE.

(Second Notice.)

A FURTHER perusal of this very voluminous report of 771 pages gives us an insight into the prevailing opinions of the military and medical chiefs of the Army on Army medical organisation. His Royal Highness the Commander-in-Chief considers that young medical officers would best learn discipline by being attached for at least three, and if possible, five years to a regiment; while all the senior medical officers concur in the necessity for the re-introduction of the examination for promotion. Professor Longmore's evidence upon this point must carry the greatest weight. He tells the Committee that in the German service—in consequence of finding the necessity for it in the Franco-German war—the following, among other regulations, were issued to ensure that medical officers kept up their knowledge. He has to go through a three-fold examination. He has first to write an essay on a subject that is sent to him from the war office; next he is subjected to an oral examination and a practical examination as follows, viz., three important surgical operations: 1. An amputation; 2. Ligature of one of the intricate arteries; 3. The resection of a joint. If he fails in the performance of one of these he may select for himself another of a corresponding kind. If he fails and is allowed

colleagues declined to attend. A letter of apology had also been received from Professor Struthers, of Aberdeen.

The Chairman said they had not a single word to say against the principles of the Bill; but with regard to the provisions there were considerable differences of opinion. After describing the constitution of the Boards which the Bill proposed to establish, Dr. Balfour remarked that the treatment of the Corporations amounted to a gratuitous insult.

Dr. Smith moved the following resolution, which was seconded by Mr. Imlach:—

“While approving generally of the objects of the Medical Amendment Bill, this meeting is of opinion that in the constitution of the Medical Board for Scotland the representation proposed to be assigned to the corporations is quite inadequate, and ought to be increased.”

He pointed out that, as the Bill at present stood, the corporations would not have their fair share of representation on the Medical Council, so that, if an appeal were made from the Board to the Council, it would practically be an appeal from the Board to the Board, and the complete control of medical education in Scotland would be transferred to the Universities. Why this should be so seemed mysterious. The talk on the other side of the border about the low standard of qualification in Scotland could only be ascribed to jealousy. It would be very hard if the fate of the Scottish corporations should be decided by the reports circulated by a few Englishmen.

Dr. Brakenridge proposed, as an addition to the original motion, the words, “Further, that by equality of representation or otherwise provision be made to ensure that one of the two members of the Medical Council elected by the Medical Board for Scotland shall be a representative of the corporations.”

Dr. Smith intimated his willingness to accept the addition, but recommended the omission of the words, “by equality of representation or otherwise.”

After a few remarks by Dr. Argyll Robertson, Dr. Charles Bell, Mr. Joseph Bell, Dr. Dickson, and Dr. Balfour,

Dr. Haldane moved, “That all candidates for the final examination of the Medical Board in Scotland be required to pay a uniform fee.” In supporting this resolution, he referred with satisfaction to Dr. Struthers' announcement that the Universities were willing that Scotland should be specially excluded from the operation of that part of the Bill to which his resolution referred. Dr. Struthers' letter was instructive, because it admitted what was an open secret before, that the Universities had been consulted before the Bill was brought before Parliament.

Dr. Keiller seconded, and the motion was carried.

Dr. Duncan moved, “That provision be made that at the final examination of the Medical Board no student shall be examined by his own teacher.”

Considerable discussion ensued on this resolution, which was eventually carried, after two amendments had been rejected, and the meeting closed with a vote of thanks to the Chairman.

THE MEETING AT THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE annual assemblies of the Fellows of the College and of the Irish Medical Association came off on Saturday and Monday last, and were occasions of very special interest. The Fellows assembled at 3 p.m., the chair being occupied by Mr. Barton, the President, and proceeded to the consideration of the annual report, the details of which, however, did not give rise to any debate. Arising out of the report, motions of much importance were presented to the Fellows. Dr. Thornley Stoker moved the proposition foreshadowed in our last issue, to the effect “that in the opinion of this College the present method of electing professors and examiners is unsatisfactory, and that the Council be recommended to seek for such alterations in the charter as shall enable these elections to be made by the vote of the entire Council, or such part of it as may

be present; not less than two-thirds of the whole number, including the President or Vice-President, to constitute a quorum for election purposes.”

The resolution was seconded by Dr. Whistler, of Bray, and was opposed by a section of the Fellows, who urged that the existing system had worked sufficiently well, and who moved as an amendment that any proposition involving a change of charter should be the subject of a notice of motion and a special meeting. It was pointed out *contra* that any motion arising out of the annual report was usually discussed without notice, and, furthermore, that the effect of remitting a subject to a special meeting was to limit its settlement to the metropolitan Fellows, inasmuch as the provincial members of the College could not be expected to come to town for such special occasion. Eventually the amendment was negatived, and the motion passed without a division by a large majority.

Dr. Jacob then moved the following resolution:—

“That this College approves of the determination evinced by the Council to ensure the *bond fides* of attendance on courses of medical study, but is of opinion that attendances purporting to be given by persons who are engaged during the usual hours of medical study in other engrossing avocations is not a *bond fide* fulfilment of the four years of study required by the General Medical Council, and therefore ought not to be recognised by this College as sufficient qualification for the Letters Testimonial of the College.”

Dr. Jacob proceeded to give the history of the establishment, in 1879, of night lectures by the Ledwich School and the Carmichael College for students who are engaged in offices and shops during the day, and the action of the Council thereon. He stated that previous to that date something more than strong suspicion had existed that persons presented themselves for the College examinations on the faith of fictitious certificates of attendance on courses of study at which it could not be pretended that they had been present, considering that they were compelled to be elsewhere all day and every day; and he adduced one case out of many in which a student, who had been engaged up to a few months previously in a bank, was passed upon the faith of a full supply of these false certificates, and immediately elected surgeon to one of the chief hospitals of the city, where he had responsible charge of the lives and health of the inmates in less than a year after his descent from the office stool. These abuses, Dr. Jacob observed, had been long suspected, but they were not acknowledged or proved until these schools publicly advertised that they were catering for such students by means of lectures delivered at night. At once the Council of the College had taken action and condemned the system, with the result that the Carmichael College immediately abandoned the practice. The Ledwich School, however, though it stated its willingness to conform to the wish of the College, and, though it had since been reminded by a second resolution of the Council, had continued the system, and had encouraged this class of students to set the College at defiance.

Dr. Jacob stated the object of his motion to be to induce the Fellows to strengthen the hands of the Council in putting down this traffic in fictitious certificates; and he urged that it was dishonest and discredit-

"That the College, instead of passing any order at the present meeting regarding night lectures, request the incoming Council to forward a copy of the arrangements for securing the attendance of students at lectures and hospital to every lecturer and clinical teacher recognised by the Council with a request that they will aid in carrying out these arrangements."

On this amendment being moved, Mr. Stoker, of the Ledwich School, withdrew his frugal proposition to remit the subject to the incoming Council, and seconded it; and it was thereupon passed by a majority of 28 to 16, Dr. Jacob's motion being therefore superseded, and not put from the chair.

This narrative of what did really occur becomes necessary, in consequence of the publication in the newspapers of a totally untrue statement that Dr. Jacob's resolution against night lectures was negatived by a large majority of the Fellows. In fact, no resolution against night lectures was submitted, nor did the night lecture party venture to take the voice of the College which, they say, was in their favour, nor was the resolution against sham study (which they seem to consider applicable to night lecturing) voted upon by the Fellows.

Dr. Kidd's amendment, which was eventually adopted, could not be objected to by the opponents of sham study, except on the ground of its weakness. It was clearly the duty of the Council to circulate its certificate regulations, and it has already done so. If there is anything to be gained by a further circulation backed by an appeal to teachers to be honest in observance of the rules, by all means let the Council repeat the issue.

But we do not in the least believe in the efficacy of remonstrance against practices which are ingrained by long years of custom, and which have the additional charm of paying right well. The large majority of the Dublin teachers who would be likely to regard the appeal of the Council, have already, we believe, ceased from issuing fictitious certificates; the minority will not cease earning money in this way as long as those certificates are permitted to pass current. It is easy to comply in the letter with the suggestion of the College that a roll shall be called, and to evade the spirit of that suggestion by taking no care whether the name is answered for by the student himself or by a single student for half-a-dozen others; it is equally easy to fulfil the order by keeping an hospital attendance book, but to take no cognisance of the fact that the said book is signed at 9 a.m. by students who are hard at work in office or shop at 9.30.

The College has failed and will fail to make teachers honest by persuasion, and so long as it continues gravely to receive as genuine the proofs that a student who is in a place of business at a given period is also beside his hospital teacher at the same moment, so long will certificates that he is in both places at the same time be saleable and sold.

The next business of the Fellows was the following motion by Dr. Kidd, with reference to the Medical Bill:—

1. That the incoming Council be recommended to have the Medical Acts Amendment Bill further amended, so as to establish and maintain a closer supervision over medical education on the part of the College than the present Bill proposes to do.

That it appears to the College this could best be done

by defining in the Bill that all previous examinations should be conducted by the "medical authorities."

2. That the Board examination should be accepted by each of the medical authorities for the final examination.

3. That candidates who have passed the previous examinations of any medical authority and the final examination by the Board, should receive the qualifying diploma of such authority, and be registered in right thereof.

This motion, though heralded by a violent denunciation of the Medical Bill, was in no sense hostile to the measure, and, being a wise and sensible proposition for amendment, was at once accepted by the College and passed *nem. dis.*

(To be continued.)

EXECUTIONS AND THE PUBLIC PRESS.

WHEN, some years ago, the Home Office decided that for the future executions should be carried out in private instead of in public, as heretofore, most right-minded people experienced a sense of relief, from the thought that from that time the eye and the senses generally would be less offended by the parading of revolting details before the public. Such people were, however, disappointed. Since then a portion of the daily press has done its best to frustrate the wholesome intention of the Government. Every scrap of information, every disgusting little detail, that it has been able to collect respecting the horrors of an execution has been made public with an effusiveness and an unctuousness that savour very much of gloating, and mercenary gloating to boot. And these gentlemen are not satisfied that they are excluded from executions; they would fain be admitted, "if only to protect the interests of the public." Who wishes them "to protect the interests of the public?" Are not the public already efficiently represented by their duly authorised representatives—the sheriff, the chaplain, the gaol surgeon, the governor, and the warders? These are more trustworthy protectors of the "interests of the public" than irresponsible reporters, and less likely to offend the public by offensive details in the daily papers.

These thoughts are prompted by the remarks of our Scottish correspondent on the recent executions in Glasgow, and by a paragraph which appeared in the columns of a provincial daily. We give the paragraph (omitting names) exactly as it appeared, and leave it to our readers to judge for themselves whether they ever saw a piece of sillier (because bare-faced) special pleading:—

"The decision of the visiting justices . . . not to admit reporters to witness the execution of . . . will not improbably call greater attention than before to this somewhat delicate question. The balance of opinion appears to be that, without in any way wishing to encourage sensational writing upon such dismal affairs, the presence of reporters is desirable, if only to protect the interests of the public. Many a London journalist could, if he would, tell somewhat startling stories as to the bungles which at one time or another have marked the efforts of public executioners; and one of these functionaries was never allowed again to operate after a terrible blunder—seen by the reporters, and duly noted—which he perpetrated at Leeds some six years since. But what chance would there have been of this becoming known if the only witnesses had been those

personally interested in keeping it quiet? The present haphazard system of leaving the question of admitting reporters to the discretion of the high sheriff or the visiting justices is provocative of much friction, and might, in certain instances, prove a veritable premium upon bungling."

The question of money-making under the guise of philanthropy is always a "delicate" one. What the writer means by "balance of opinion" is, no doubt, the balance of his own opinion and of that of other reporters. That it is a fact that the balance of public opinion is in favour of private executions being made public for the benefit of reporters and their employers we indignantly deny. Even if public taste were so degraded, it would be the duty of the leaders of public opinion to elevate it, and not to pander to it by acting the part of procurers. If, however, these gentlemen honestly think themselves the protectors of the "interests of the public," and if they honestly believe that their presence at executions would really prevent this "veritable premium upon bungling," we see no objection to their fulfilment of a sacred duty, provided they are first sworn to spare the public a repetition of those degrading details to which they have been hitherto prone. One more part of the paragraph deserves notice—viz, that relating to the haphazard system of admitting reporters or not, according to the whim or discretion of the high sheriff or visiting justices. We would suggest that the haphazard system be improved away, and that the admission of reporters to executions be placed upon a satisfactory basis—i.e., that the Home Secretary take from the high sheriff and visiting justices the discretion of admission. "Much friction" would doubtless be avoided by this simple proceeding.

Notes on Current Topics.

Pleasant for Jack.

THE advocates of unrestrained infection have just enjoyed what will probably be to them a delightful proof of the wisdom which has animated them to pursue a course resulting in the virtual repeal of the Contagious Diseases Acts. In a letter to the *Daily Telegraph* on Friday last Dr. A. Conan Doyle, of Portsmouth, has given irrefutable evidence of the all too certain efficacy of the method which Mr. Stansfeld and his followers will by and bye receive the credit of having introduced, for national deterioration of physique. The following extract from Dr. Doyle's letter speaks volumes for the effect which that thrice ill-advised motion in the House of Commons is producing:—"Last week a large transport entered Portsmouth Harbour with time expired men from India. Upon the same day thirty diseased women left the hospital with the avowed intention of meeting that transport, and there was no law to prevent it." Divested of all additional details this bare statement of a fact contains a more crushing exposure of the fatuous proceeding of sentimentalists than the most eloquent exposition of the evils to which society is exposed to by their wretched meddling with questions involving scientific considerations.

Dr. Doyle's comments on the action of the Contagious Diseases Acts opponents are, however, well worthy of

reproduction. He continues:—"I say that, if an unfortunate soldier coming home to his native land after an absence of years, and exposed to such temptation should yield to them, and entail disease upon himself and his offspring, the chief fault should not lay at his door. It surely emanates logically from those enlightened legislators who set loose those thirty bearers of contagion, and their like, upon society. For fear delicacy should be offended where no touch of delicacy exists, dreadful evils are to result, men to suffer, children to die, and pure women to inherit unspeakable evils. Loose statements and vague doctrines of morality may impose upon hasty thinkers, but surely when the thing is reduced to its simplest terms, it becomes a matter of public calamity that these Acts should be suspended for a single day, far more for an indefinite period. The apostles of free-trade in infection have worked to such good purpose that within a few weeks the streets of our naval stations have become pandemonia, and immorality is rampant and self-assertive where it lately feared to show its face. Property has much depreciated near our public houses since the suspension of the Acts on account of the concourse of vile women, whose uproar and bad language make night hideous. I venture to say that, were the old laws enforced again to-morrow, there would still in a hundred years time be many living who could trace inherited mental or physical deformity to the fatal interregnum which the champions of the modesty of harlots had brought on." Other places than Portsmouth tell the same tale, as witness the following resolution of the Dover Town Council, a copy of which has been forwarded to the Home Secretary—"The Dover Town Council views with deep regret the suspension of the Contagious Diseases Acts, and trusts that their full operation may be reinstated at an early date."

Careless Patronage.

MUCH regret will be experienced at the announcement now being made public, that the President of the Royal College of Surgeons, Sir Spencer Wells, Bart., has permitted his name to be used in connection with an institution that is at least regarded by many members of the profession with suspicion. We refer to the St. John's Hospital for Skin Diseases, in Leicester Square, the management of which has been very unfavourably commented on in the past, and in aid of which a bazaar is about to be held under the patronage and in the presence of, among others, the eminent surgeon named above. Such a proceeding on the part of Sir Spencer Wells, is somewhat unfortunate, for it necessarily commits the distinguished College he so worthily represents to approval of a special hospital, the best that can be said about which is that it occupies a position of questionable stability; and we cannot refrain from an expression of very sincere regret at the association of a leader of English surgery with an institution which fails to command universal respect and sympathy.

THE President of the Royal College of Surgeons of London—Sir Spencer Wells—has issued cards of invitation to a *conversazione* at the College, at nine p.m., on Wednesday, June 20th.

The Dublin Sham Certificate Trade.

STIMULATED, probably, by the agitation against fictitious certificates which has been growing in strength for the last two years, the Board of the University of Dublin has issued the following notice:—

NOTICE is hereby given that, in future, Students in Arts of Trinity College, who have entered the Medical School during or since 1880, will not be required to produce certificates of attendance on lectures previous to admission to the Medical Examinations, but will be required, instead, to fill up, and lodge with the Medical Registrar, forms of Notice which will be issued before each examination. There will, therefore, be no general issue of Certificates by the Professors; but those students who may require them for presentation to other examining boards, can obtain them by application to the Medical Registrar. Students who have matriculated before 1880 will have to produce their certificates as heretofore.

N.B. Only those students who have attended three-fourths or upwards of the Courses of Lectures for which they have entered can present themselves for examination.

By order of the Medical School Committee,
HENRY W. MACINTOSH, Medical Registrar.
March 16th, 1883.

We trust that the example of Dublin University will be followed by every College or University throughout the Kingdom. Certificates have ceased to have any value, except, as the Reverend Dr. Haughton says, as receipts for money paid. They are not required by the English licensing bodies, and certainly the specific statement as to attendance which appears on the face of a schedule is far more reliable than any quantity of purchaseable certificates of "diligent" attendance.

Dalrymple Home for Inebriates.

AT the meeting held on May 31st at the Mansion House, for the purpose of advocating the cause of the Dalrymple Home for Inebriates, there was a considerable attendance of influential friends of the movement, the Lord Mayor, Mr. Alderman Knight, presiding. In the course of his remarks, the chairman urged that at least £6,000 should be raised for the committee to be able to carry out the object in view; towards this one member had offered £500, provided nine similar amounts were forthcoming, either in single sums or in small amounts; and the Lord Mayor added that a friend of his own had promised to give £25, if nineteen others would come forward with a similar amount. In conclusion, he said that he felt convinced, after much experience as a magistrate, that there was such a person as an habitual drunkard, utterly unable to resist the temptation to drink, and he should be glad to see a Home founded and at work, to which such unfortunates could be taken. As a magistrate, he would like to have power, under an Act of Parliament, when habitual drunkards came before him, to send them to such a home, where they could be taken care of, and reformed from the dread habit of drunkenness, not only for the benefit of the drunkard himself, but also for society at large. During the meeting a letter was read by Dr. Norman Kerr, in which the writer, Mrs. Dalrymple, widow of the late Dr. Dalrymple, stated her willingness to increase her donation from £500 to £1,000, in the hope that the whole amount required might thereby be sooner subscribed. Dr. Farquharson, M.P., moved, and Dr. Alfred Carpenter seconded, a resolution to the effect that "The diseased state of many inebriates calls for their residence in some

institution where they can be placed under curative treatment, where the surroundings will be favourable to cure, and where there will be no temptation from the presence of intoxicating liquor." Several other resolutions were carried, and the meeting was altogether a very successful and encouraging one.

The Irish Prisons Board and its Medical Officers.

OUR readers may remember that some months since we recounted the history of an attempt by the Irish Prisons Board to dismiss one of the medical officers of the Dublin city prisons because he was indisposed to answer questions which the Board—contrary to law—was seeking to put to him. That officer, when threatened with dismissal, set the Board at defiance, and the Board, after much bluster and a remarkable display of ignorance of its own law, was obliged to cave in and leave the officer undisturbed. The experience thus acquired has not, it would appear, taught the Board to be wise, for it has recently attempted to superannuate another surgeon of the City of Dublin prisons as a punishment for his having refused to examine civil servants as to the condition of their health unless he be paid for doing so. That duty is a perfectly new one, thrust upon the prison surgeons in defiance of the 27th section of the Irish Prisons Act of 1878, and is a service entirely outside prison duties, performed for persons who are able to pay and who are not prison officers.

The second attempt of the General Prisons Board has resulted in greater misfortune than the first, for that Board has been obliged to withdraw its superannuating order, and leave the officer in possession of his office and full pay.

If permitted to offer a little advice to the Irish Prisons Board and the Local Government Board, we would recommend them to save themselves these public humiliations by employing some competent person to read their Acts of Parliament, and—when read—by striving to restrain themselves within the limits of those Acts.

A Too Successful Experiment.

IMMEDIATE explanation should be given of the facts surrounding the statement made in the House of Commons in reply to a question from Mr. Hopwood. The truth about the matter is that an official of the National Vaccine Establishment, Dr. Cory, of St. Thomas's Hospital, who entertains the view that inoculation from a true Hunterian chancre is not possible, has submitted himself to experiment with a view to testing the theory. After four times failing of success, he has at length, unfortunately, succeeded too well, a hard chancre on the arm being the result. Notwithstanding that the sore has been cut out, secondary and tertiary symptoms have followed in due course, and now we regret to say Dr. Cory is wholly incapacitated from regular work. Of course, capital will be made out of this event by anti-vaccinators, but with what small cause the history will prove.

THE Staines Urban Sanitary Authority have been fined £20, and ordered to pay 10s. costs, for causing or suffering offensive matter to flow into a watercourse communicating with the Thames.

Hospital Sunday in London.

THE annual collection at the various churches and chapels in the metropolis took place last Sunday, and in the Jewish synagogues the day previous, and, judging by the sums already sent in to the Mansion House, the prospect of a larger amount in the aggregate than heretofore is almost assured. Last year the total was between £35,000 and £36,000, which was considerably higher than that for any previous year. On the present occasion everything was in favour of the fund—the weather brilliant, without excessive heat, London full, and the State attendance of the Lord Mayor and suite both at St. Paul's Cathedral and Westminster Abbey. The only drawback is the discovery of an attempted fraud by persons at present unknown, who at the last moment sent a forged circular round to the various places of worship in the Lambeth district, intimating that collectors from the Mansion House would call for the amounts collected in order to save the trouble of remittance to head-quarters. Fortunately the police had timely warning, and it is hoped that no sums were paid over to these *soi-disant* representatives of the Hospital Sunday Fund before the police had time to give the necessary warning.

The Tenure of Office of Irish Workhouse Surgeons.

THE Council of the Irish Medical Association has followed up its remonstrances against the attempt of the Irish Local Government Board to put the union officers under the foot of the guardians by a communication which it has sent to every workhouse medical officer in Ireland. This communication states the case, and gives the reiterated opinion of Mr. Purcell, Q.C., as to the illegality of the General Order promulgated by the Board, and proceeds as follows:—

“The Council of the Association has in vain solicited the Board to amend the objectionable articles of the recent General Order, or to submit the legality of their action for confirmation by the Law Officers of the Crown; but having been advised that the validity of the General Order can be tested at law only by an officer who has been dismissed or suspended by a board of guardians, the Council, therefore, is prevented taking the necessary steps to set aside the rules in question by application to the Court of Queen's Bench.

“From Mr. Purcell's opinion it follows that a dismissal or suspension by a board of guardians is wholly invalid; and that an officer is entitled (notwithstanding the General Order of the 18th of December, 1882, or any vote of the board of guardians founded thereon), to continue in his office, and to receive and recover at law, all his emoluments until he is formally removed by the Local Government under section 33 above quoted, the legal responsibility of such removal devolving solely upon that Board.

“The Council is prepared to consider the case of any officer dismissed or suspended by a board of guardians under this Order, with a view to proceedings to contest such dismissal at law where the circumstances appear to justify such action.”

We trust that an opportunity will arise before long to enable the Association to set aside this act of the Irish Local Government Board, for it would, in our opinion, be a disaster if the Board were permitted to shift its responsibility for dismissal to the guardians, or any one else.

It appears to us somewhat discreditable to the Board that we find it following the example of the Irish Prisons Board in attempting to override the Act of Parliament to the disadvantage of its own officers. If the Board is really in any doubt that its act is *ultra vires* and invalid it can readily obtain an opinion on the subject; but if it will not take that course, we think the Irish Medical Association should, as it proposes, do so on the very earliest occasion.

The Social Science Congress.

WE are informed that the subjects selected for discussion in the Health Section at the forthcoming annual meeting of the Social Science Congress, which is this year to be held at Huddersfield in October, are—

1. Is the modern system of education exerting any deleterious influence upon the health of the country?
2. Is it desirable to take any, and what further measures, to prevent the spread of zymotic diseases through the milk supply of our towns?
3. Is it desirable to amend or extend the Habitual Drunkards Act, and if so, in what direction?

Volunteer Medical Organisation.

THE executive committee of the Volunteer Medical Organisation held a meeting on June 1st, at Charing Cross Hospital, when the secretary reported on the considerable progress being made by the movement. Volunteer surgeons to the number of 51 have already placed their names on the general committee, and all the medical schools in London have now representatives in either the executive or general committee. The secretary was directed to convey to Messrs. Savory and Moore the thanks of the committee for the kind grant of 20 field haversacks complete, for the use of the Ambulance Company at Charing Cross Hospital. The National Aid Society have very courteously allowed the organisation to hold committee meetings at, and to have letters addressed to, their offices, 5 York Buildings, Adelphi. Besides Charing Cross Hospital, where a trained company already exists, St. Bartholomew's is about to take up the movement on a large scale. The London and St. George's are also moving in the matter.

The Council of the Royal College of Surgeons.

THE three members of the Council of the Royal College of Surgeons who retire this year by rotation are—Mr. John Cooper Forster, Vice-President of the College; Mr. John Birkett, President of the College in 1877; and Mr. Prescott G. Hewett, also a past President. Of these Mr. Cooper Forster only will seek re-election; and it is probable that most, if not all, of the following Fellows will be candidates for seats in the Council at the ensuing election:—Mr. George Lawson, of the Middlesex Hospital—Member, August 9, 1852; Fellow, December 17, 1857. Mr. Nottidge Charles Macnamara, of the Westminster Hospital—Member, April 17, 1854; Fellow, June 10, 1875. Mr. Oliver Pemberton, of the Birmingham General Hospital—Member, April 12, 1847; Fellow, April 18, 1875. Mr. Robert Brudenell Carter, of St. George's Hospital—Member, December 12, 1851; Fellow, 1864. Mr. Sydney Jones, of St. Thomas's Hospital—Member, April 4, 1853; Fellow, December 11, 1856. Sir William MacCormac, of

hygiene, to have taken his force so far with such little loss. Nor ought we to omit the name of Herodicus, one of the preceptors of Hippocrates, and the first to introduce gymnastics on scientific principles, not only as a curative, but also as a preventive measure. The works of Asclepiades, who boasted that he would never be sick, and did, indeed, die of a fall, and those of Aretæus, doubtless contained reference to preventive medicine, whilst those of Galen, which extended to 300 volumes, the majority of them now lost, furnished many of the precepts on which later hygiene was based. On the other hand, the myth which makes Health, or Hygieia, the daughter of Asklepios (whom we call Æsculapius) no doubt arose from an instinctive perception of the value of medical science in preserving health as well as in the cure of disease. We may also be permitted to believe that the honours paid to his sons Machaon and Podalirius were due, at least in part, to their hygienic foresight as well as to their medical and surgical skill. Besides the writers already quoted, it would be unjust to omit the name of Aristotle, whose writings include important hygienic precepts. The general life of the Greeks was eminently hygienic, being mostly out-door and under favourable conditions, persons even of high position taking part not only in active occupations, but in labours that might be even considered menial by the unthinking. The honourable place that athletic games held is a point of resemblance between the Greeks and our own countrymen that ought not to be lost sight of. Nothing is more conducive to health of body and mind than active exercise in the open air, and the splendour of Greek literature, art, and knowledge is a sufficient answer to those who are afraid lest athletics should develope the muscles of our youth to the detriment of their brains.

Among the Romans the care bestowed upon the provision of pure water—with which is connected the celebrated name of Frontinus, as *Curator Aquarum*—and their elaborate system of drainage, prove that they had correct ideas on some of the fundamental questions of hygiene. Their fondness for bathing and extensive establishments for that purpose remain monuments of the next to godliness which even at this distance of time we, with all our boasted civilisation, have been unable to emulate. The more recent discoveries in the Campagna have still further shown that they were fully aware of the conditions which alone could make that now pestilential region habitable, as a system of subsoil drainage has been revealed that is a reproach to the ignorance and supineness of modern times. Nor was Rome the only city of antiquity that was efficiently drained, for we have evidence of it at Agrigentum at least; but Rome was certainly among the oldest of which we have actual remains, the beginnings of its great cloaca going back at least five and twenty centuries. Another direction in which the Romans showed great knowledge of the principles of hygiene was in the management of their troops on the march and during war. The rules for encampments given by Vegetius are excellent, and to the great care shown for every detail of sanitation must be attributed the comparatively small loss which the armies of the Romans appear to have sustained. We may say, indeed, of classical times generally, that there was a remarkable absence of devastating epidemics, none of those on record approaching in fatality and intensity the great plagues which swept over Europe down to quite modern times.

In taking a cursory retrospect of the Old World in its medical aspects, I should be inclined to say that on the whole its medicine was as much preventive as curative. Two things seem to indicate this:—1. There was a dread and impatience of disease, so much so that men were known to commit suicide to escape it; like the aged Indian who slew himself at the tomb of Achilles, for fear he should die of disease, from which he had through life been free. 2. The sentiment of pity for the weak and the oppressed appears to have been absent; there was a tendency as we find among animals and among savages to hold a sick man of little account, as useless to the State, and the sooner

got rid of the better. Hence, perhaps, the curious fact that we have no record whatsoever of public hospitals or infirmaries for the sick poor during the classical period—the earliest being as late as the reign of Justinian.

From the time of the decline and fall of the Western Empire the progress of hygiene appears to have been arrested. Some few of the treatises of the Greek and Latin physicians survived, others were known only as translated from the Arabic, &c., whilst wholesome traditions of the hygienic life of Greece and Rome appear to have decayed, and we pass into a dark and dirty period when fanaticism usurped the place of religion, and dirt became the odour of sanctity; indeed, it may be said that no writings on science during this dark period were worth notice, except those attributed to our own Roger Bacon.

One of the first really practical writers on the subject of hygiene was the well-known Ludovico Cornaro, a noble Venetian, who, after a youth of intemperance and excess, reformed his ways and kept so strict a watch over his diet and habits that he prolonged his life to the age of 100 years, dying in April, 1566. Twelve ounces of solid food and fourteen ounces of liquid, in this case wine, were all he allowed himself, but then he led a life that was less life than mere vegetation, for he was careful to avoid heat, cold, fatigue, grief, watchings, and every other excess that could hurt his health. "How," says Sir John Sinclair, "could the business of the world be carried on if every man, like Cornaro, were to begin to follow such a system at the fortieth year of his age?" Yet the value of Cornaro's treatise was very great, for it was an indisputable proof that life might be maintained, and even health, upon much smaller amounts of food than were often taken, and further, that temperance and moderation are the best resources against both disease and accident. He recounts how he had been upset in a carriage, and been in consequence severely bruised and had an arm and leg dislocated. The doctors wished to bleed and purge him, but he confident in his temperate habits, desired merely that his limbs should be set and he himself be let alone, after which he made a rapid and complete recovery. The advanced age to which he lived, and also the great ages of Pope Paul Farnese, Cardinal Bembo, and the Doges Lando and Donato, whom he cites, all of whom were men of regular and temperate lives, contrast remarkably with the short lives of the average of men of the time, old men being very rare, and even those who had passed the half century uncommon.

Of the other writers of the period I will only refer to Thomas Philogus of Ravenna, on account of his strong protest against intramural interment, thus anticipating by some three centuries the happily fruitful labours of our distinguished countryman Edwin Chadwick.

The next writer of eminence was the celebrated Sanctorius, a native of Istria and a professor of Padua. He wrote a work on health, entitled "*Medicina Statica*," and he also began the era of exact observation by his well-known experiments with the weighing-chair, by which he endeavoured to show the weight of the insensible perspiration. His experiments were very crude and inaccurate; but they were in the right direction, and his work may be considered as marking an epoch in the advance of scientific observation. The aphorisms in his book are couched in quaint, and even fantastic, language, but many of them are sound when stripped of the vagueness and mannerism of the time. He is particularly severe upon a certain "*Staticomastix*," who had criticised him, and had asserted that a plentiful perspiration did not take away from the body one ounce of weight.

The writers from the time of Sanctorius down to the end of the seventeenth century call for little attention, as they seem to have added but little to the knowledge of the time. The remarkable physical discoveries of the close of that century and throughout the whole of the next certainly paved the way for more exact observation in medicine, both in its purely medical and etiological aspects. Accordingly, we have the observations of Boerhaave and Haller, and a host of other names of

distinction, all representatives of progressive medicine, either directly or indirectly connected with the advance of hygiene. Sketches of the various writings of this and preceding periods are given by Mackenzie in his "History of Health," by Sir John Sinclair, and by Hallé in his long article on Hygiene in the "Encyclopédie Méthodique."

It is a little difficult in a necessarily restricted lecture to convey any exact idea of the way in which modern hygiene became formulated into so much of a science as it can at present lay claim to; but I will attempt to make a brief sketch of its more salient points. In the eighteenth century there were several important questions inquired into, and to a large extent solved, of which the chief were: (1) The influence of air as a factor in the spread of disease; (2) The true cause and prevention of scurvy; and (3) the prophylaxis of small-pox. Taking the last first, we may say that the introduction of inoculation was a most important step, even although we must admit that it introduced a greater danger to the community at large than could be compensated for by the protection to individuals. But it was the first step on the road which led at the close of the century to vaccination, one of the most signal triumphs of preventive medicine, and in our own time to the magnificent results obtained by the renowned Pasteur, results which seem pregnant with so much hope for the future of our race.

The inquiry into the causes of scurvy was another step in advance of the most signal importance. No one in the present day can form any idea of the ravages that terrible disease produced. All long voyages were imperilled by it, whilst the very existence of England depended upon her fleet, which had frequently to return to port absolutely crippled with scurvy, in some cases as many as 10,000 men being landed from the Channel fleet helpless. Although so far back as the 17th century the efficacy of fruits and fresh vegetables as preventives had been surmised, if not actually noted, it is really to the renowned Captain Cook that the credit is mainly due of having established this important fact. That eminent navigator never lost an opportunity of taking on board fruits and fresh vegetables whenever he could, and the result was that he was able to bring home from a lengthened voyage crews in almost perfect health and condition—a thing never before known.

The recognition of foul air as a factor in disease was certainly begun in the last century, when the brilliant discoveries in pneumatic chemistry made by Lavoisier, Cavendish, Priestley, Black, and Rutherford threw such a flood of light upon a previously obscure subject, and opened the whole immense vista of the boundless science of modern chemistry. It was only then that the physiology of respiration could be even partially understood, and the changes recognised which take place in the respired air from the lungs of man. The great disaster of the "black hole" of Calcutta, and the terrible effects of the gaol fever, investigated by Howard and others, pointed to foul air as a main factor in the propagation of disease and death; and this was further corroborated by the observations made by military surgeons that outbreaks of typhus (or putrid fever) were most rapidly arrested when troops were encamped and scattered widely over the surface of the ground. It was reserved for the later researches of Neill Arnott and other hygienic observers of the present century to prove the still more important fact that foul air is the main cause of the still more general and fatal class of destructive lung diseases, which in this and in other lands cut off so many of the brightest and the best.

Another important discovery of the last century was the determination of the cause of the well-known lead colic by Sir George Baker. This opened up the large field of metallic poisoning which has received so much elucidation and proved of such importance in reference to the water-supply of the communities.

In the present century we have to point to the establishment of the fact of the water carriage of disease, with which the name of Snow is so honourably associated, the

differentiation of continued fevers by Stewart and Jenner, and their connexion with the poison of infected excreta by the labour of Budd and other eminent men. To those we must add the elaborate investigations into the modes of propagation of cholera, dysentery, and other tropical diseases, and the means by which scarlet fever, diphtheria, &c., are carried from place to place by various channels of communication. It would be unavoidable, even if it were possible, to enter into details on this point, but there is one branch of the subject on which we must dwell for a little. No inquiry can assume a scientific form unless it has a numerical basis to work upon, and therefore it behoves us to note the starting-point of such a basis in hygiene, if we can find it. This we do find in the collection of statistics, a beginning of which was made a long time ago in the bills of mortality kept in this country. We know how imperfect those were, and how even the population of this country was not correctly known until within the lifetime of men still living. But still beginnings were made, and the question taken up more and more enthusiastically by enlightened men, until at last the Government Statistical Department was formed, and that remarkable series of reports begun which will immortalise the name of William Farr. From that time the future of hygiene was assured; for there was sound ground to work on, and if we add to that the valuable reports on the health of towns published by the Commission of which the present Duke of Buccleuch was president, we shall have stated some of the most important foundations of modern sanitary science. Those reports disclosed a state of things little dreamt of, and the statistical returns compiled by Dr. Farr showed how much the life and health of the nation were dependent upon the conditions in which its individual members were placed. The establishment of the General Board of Health, under Mr. Chadwick, was one of the valuable outcomes of this remarkable movement. Although the original Board of Health was brought to an end in 1854, yet its work has been continued and expanded under Mr. Simon and his colleagues and successors, in spite of many difficulties and obstacles.

The part which the public services, such as the Army and Navy, played in the progress of hygiene, was very important, as might indeed be expected; for under no other circumstances could bodies of men be so well observed, and the effects of surroundings and conditions upon health noted. Accordingly we have a long roll of names connected with those services which must ever be remembered with honour; in the Navy we have such men as Lind, Blane, Trotter, Burnett, &c.; and in the Army, Pringle, one of the most philosophical physicians who ever lived, Brocklesby, Fergusson, McGregor, and a host of others. The labours of the late Sir Alexander Tulloch, Deputy Inspector-General Marshall, and Assistant-Surgeon (now Surgeon-General) Balfour, in collecting and arranging the army statistics, were of the highest value, and it is not too much to say that the publication of the first army medical statistical report marked an epoch in hygiene, especially in that part that deals with climatology. It exposed the fallacy of the common notions of acclimatisation, of the advantages of a seasoning fever, and similar ideas. It showed also that it was possible for men of temperate habits and in hygienic conditions to live and thrive in the tropics, whilst the death and sickness that were unfortunately so common were due much more to the ignorance and folly of man than the influence of climate in any form. The truth of that is to be seen now when life in the West Indies is actually healthier, especially for young soldiers, than service at home, whereas sixty years ago a tour of service there was looked upon as almost a sentence of death. But perhaps the most remarkable contribution the Army has made to sanitation has been by the evidence given to the Royal Commission of 1857, which met after the Crimean war to investigate the causes of the sickness and mortality of our troops. The results of that Commission

are well known, and from its publication may be dated the reforms which have been productive of much advantage both to our own and foreign armies, and to the civil population as well. The paramount influence of foul air in the production of lung disease was proved to demonstration, and the art of ventilation was placed upon a secure foundation. The Barrack Hospital Committee, of which Dr. Sutherland and Captain Douglas Galton were the active members, laid down a series of regulations for the construction of barracks and hospitals, which have been followed with the utmost benefit both at home and abroad. Following this came the Indian Commission, which did for that vast dependency what the Home Commission had done for the rest of the empire. The mortality in India was found to be inordinate, and it was equally clearly traced to insanitary habits and surroundings. To recognise an evil and its cause is half way to curing it, and after a lapse of a quarter of a century we can point, not certainly to perfection, but to such an improvement as might fairly at one time have been looked upon as chimerical. The death-rate of the Army at home is only two-fifths of what it was before the Crimean war; the death-rate in India is only one-third, and the death-rate in the West Indies one-tenth.

In civil life it has recently been shown that the improvements of later times have resulted in a diminution of 2 per 1,000 in the general death-rate, and with the knowledge we now have of the causes of disease we may be sure that a general death-rate of not more than 15 per 1,000 may be confidently looked for. The remarkable immunity of soldiers and prisoners in the last epidemic shows what can be done when people can be compelled to lead fairly hygienic lives.

Although there are many names I might refer to as great writers in hygiene, abroad as well as at home, there is one which we cannot omit in a lecture like this, more especially as it is the first delivered in this museum which has been founded to his memory. Edmund Alexander Parkes did more than any other one man in this or any age to make hygiene a positive fact, a practical science, based upon not only philosophical conceptions, but actual experiments. Starting in life as an army medical officer he was able to produce during his short service in India and Burmah works upon dysentery and cholera, which will always be of the greatest value. Retiring into civil life he became eminent as a physician and teacher, and in 1855 he undertook the organisation of the hospital at Renkisi, in the Dardanelles, which was a perfect model of successful hygienic administration. Struggling with distressing and dangerous disease he continued to lead a life of intellectual activity not often accomplished by the most robust; and when, in 1860, the Army Medical School was established by Lord Herbert of Lea, Sir James Clerk had no hesitation in advising that Dr. Parkes should be secured if possible as the Professor of Hygiene. How excellent the foresight of that eminent physician was we all know, for Dr. Parkes was not only the first professor of the science in this country in point of time, but also the first in every sense of the word. The publication of his well-known "Manual of Practical Hygiene" gave us for the first time a work on the subject, which was not merely a string of opinions and surmises, but at every point brought opinion to the test of figure and experiment, where it was possible, and thus laid the foundation for a real science in the future. Similarly with his teaching he pressed upon the Government to establish practical laboratories for his pupils, where they could do for themselves as much of the experimental work as time and opportunity allowed; and he impressed upon them who studied under him the necessity of testing everything by actual investigation and bringing all statements to the proof of figures before accepting them as true. There was never probably a man of calmer and more judicial mind, a man more rigidly critical of his own work, or more kindly disposed to allow every credit to the work of others. Having known him personally for many years, during thirteen of which I was his assistant and colleague, I can bear confident testimony to

the exceeding beauty of his character, in which "sweetness and light" were never more truly displayed, and the scrupulous accuracy and care with which every investigation of his was carried out. The science of hygiene could have no purer and better founder, and its votaries no brighter and more spotless example.

URIC ACID: ITS PHYSIOLOGY AND ITS RELATION TO RENAL CALCULI AND GRAVEL. (a)

By ALFRED BARING GARROD, M.D.,

F.R.C.P., F.R.S., &c.,

Consulting Physician to King's College Hospital, London.

LECTURE I. (continued).

LET us pass on to another point in the physiology of uric acid. How can we explain the fact that, in proportion to the weight of their bodies, some animals excrete so large a quantity of such an insoluble principle as uric acid, or even as urate of ammonium, the one requiring 8,000, the other 2,400 times its weight of water at the body-temperature to dissolve it? The human subject excretes on an average in the twenty-four hours about one part of uric acid for each 120,000 parts of his weight; or, estimating the weight of a man at about ten and a-half stone, throws out about eight grains of this acid daily. This is an average arrived at from a very large number of observations, which you will find detailed in Dr. Edmund Parkes's valuable work.

In the case of the lower animals, I could find no facts on record relating to this subject, and therefore had to undertake to supply them for myself by means of observations and experiments.

In pursuit of this subject, I made observations on the relation between the daily weight of the uric acid excreted and the weight of the renal organs themselves. In the case of a lark, I found that the ratio of the weight of bird to that of kidneys was 125 : 1; in that of a linnet, 118 : 1; in that of a turkey, 172 : 1; but this latter bird was in a fattened condition, so the ratio may be somewhat misleading. Taking the lark and linnet, therefore, after calculating their daily excretion of uric acid, we find that it amounts to more than the weight of the kidneys of the same birds. Let us reflect on these facts. Is it possible to conceive, if we assume that the uric acid first exists in the blood, that the amount of this fluid passing through the renal organs could excrete as much of this principle as we have found, as a fact, to be thrown out? True, in the case of man, who excretes only one-thousandth part of the uric acid thrown out by birds, we could easily imagine this to be the process; but the more we consider the facts about birds, the more difficult does it become to believe in this explanation; and, if we go further, and hold it impossible, then the first view as to the formation of uric acid appears to me to fall to the ground.

As this question is of the utmost importance to physiology, and as its decision must necessarily be followed by weighty consequences, it is essential that nothing should be left undone which might help us to the truth. With this object before us, there arise many points which must be determined; and, first of all, we must ascertain the condition of the blood of various animals, especially with regard to the presence or absence of uric acid. I have obtained many such data from observations made during a long course of years. I have several times examined the blood of man in health, and many hundred times in various diseases; and the conclusion at which I have arrived is this: that, in absolute health, the uric acid in the blood is inappreciable by our tests, and that fluid does not contain the one hundred thousandth part of its weight of the acid; while, in gout, the blood is very rich in this principle, as I showed in 1847; that

(a) The Lunnellan Lectures for 1883. Delivered before the Royal College of Physicians of London.

being now in a third edition proves that it is fully entitled. Nor is it difficult to understand why so favourable a reception has been accorded to the volume, for it presents the whole subject in so concise and comprehensive form that it very materially assists the student in remembering the mass of facts he is called upon to show an acquaintance with in examination rooms.

The third edition of Dr. Husband's guide to practice has undergone most careful revision throughout, and in many places important additions have been made to the text, especially in the sections relating to diseases of the nervous system. The compact size of the work necessarily precludes exhaustive or even lengthy descriptions; but in every case salient features of disease, the essentials of treatment, and sufficient details of pathology and etiology are included, and are expressed in clear, accurate, and precise language. There is no burdensome repetition encountered, and in numerous instances a tabular arrangement of the matter lends invaluable assistance to the learner. As a guide to outline knowledge of practical medicine, there is no work more suitable for the use of students than Dr. Husband's "Handbook."

GRAY'S ANATOMY. (a)

It is the fate of few books to achieve an amount of success at all equal to that attained by Gray's classical treatise on anatomy; on the other hand, the number of works at all comparable with it in excellence is likewise of the smallest. Even, however, for such a manual as Gray's Anatomy is universally admitted to be, ten English editions is a very large aggregate issue, to justify which unusual merit can alone be held a sufficient cause. It is gratifying also to know that, notwithstanding the publication of many competing and lesser manuals, this standard treatise still maintains its popularity; for in this fact there is proof that systematic and laborious study is still held to be as important as ever in respect to the anatomical branches of the curriculum. This last edition of Gray's has been carefully revised, and portions of it have been re-written to meet the requirements set up by advances in discovery, especially that part devoted to microscopical anatomy. Throughout, too, there is evidence of the utmost care having been bestowed to secure absolute accuracy; and as a consequence the number of typographical errors is reduced to a minimum. In every respect the new issue of the work is worthy the reputation alike of its predecessors and of its accomplished author and editor.

ST. THOMAS'S HOSPITAL REPORTS. (b)

This volume contains contributions from members of the staff, which occupy the smaller half, and the statistical reports of the various departments, which occupy the larger half of the book. With regard to the former, we are at once struck by the paucity of information contributed by the surgical staff. On looking at the surgical report for the year 1880, we find that the number of patients admitted to the hospital was 2,299; and, again, in 1881, 2,329 patients were treated to a termination, the total number treated in the surgical wards during the two years 1880 and 1881 being 4,628. The surgical staff of the hospital consists of two consulting surgeons, four attending surgeons, three assistant surgeons, and a resident assistant surgeon. The result of such a vast number of patients is the contribution of one paper on "Six Cases of Intestinal Obstruction," treated and written by the resident assistant surgeon, Mr. Bernard Pitts, for the purpose of illustrating the advantage in such cases of making an exploratory incision through the abdominal walls, and, by inserting the hand into the cavity of the abdomen, ascertaining the exact situation and nature of the obstruction, afterwards performing any further operation that may be thought desirable, taking the precaution of waiting for a short time before undertaking the second operation, in order to avoid the occurrence of peritonitis.

Among the medical papers we notice one on "The Use of the Continued Current in Diabetes," by Drs. Stone and Walter J. Kilner. The two recorded cases do not offer much

(a) "Anatomy, Descriptive and Surgical." By Henry Gray, F.R.S. Tenth Edition. Edited by J. Pickering Pick. Longmans and Co., London.

inducement from their results for others to follow this line of treatment. The principle of its action is founded on the hypothesis that diabetes is the result of an essential neurosis, which would offer a reasonable chance of cure by the application of the constant current to the pneumogastric nerve. In the first case cited the current was an ascending one, from the nape of the neck to the forehead, the negative pole being placed in the former region, the positive in the latter. The current was of 1,500 micro-verbers in strength, and was at first continued for seven minutes. The more immediate result was improvement in the eyesight, with rapid recovery of flesh. In the course of three months the quantity of urine passed was reduced from 170 ounces on November 3rd, with sp. gr. of 1045, to 58 ounces on January 22nd. So far, everything was satisfactory, but from this date the patient became much worse, and the termination of the case is here given in the author's words:—"On the 22nd the quantity of urine was 58 ounces. It continued at a comparatively reduced standard until February 9th, on which day a large carbuncular boil began to form at the back of the neck, where the negative pole of the battery had been applied. The use of galvanism was then finally discontinued. The patient became much worse, restless, semi-comatose, with raw, excoriated tongue; unable to take food or stimulants. The quantity of urine rose to 110 and 120 ounces; the temperature remained at 98° 6° Fahr. In this condition he remained until February 21st, when it sank to 96°. On the following day he died."

In the second case the same improvement occurred as in the first, but the patient himself does not seem to have been satisfied with his progress, as we read that he left after about a month to try some other hospital.

In continuation of a former article, entitled "Annotations on Anæsthetics," by Mr. S. Osborne, chloroformist to the hospital, the author adds some further particulars. The conjunctival surface, he remarks, when repeatedly touched, loses its sensibility, and, therefore, to avoid a false impression with regard to the anæsthetised condition of the patient, first one eye, and then the other, should be touched. Dilatation of the pupils is a sign of the anæsthetic having been pushed to a sufficient extent, and the inhaler should be immediately removed from the face. Flaccidity of the limbs is no sign of cutaneous insensibility. The inhalation of ether frequently produces exanthematous patches on the face and upper parts of the body, the origin of which is to be found in paralysis of the vaso-motor nerves by the anæsthetic.

Dr. Henry Gervis believes that the employment of topical applications to the cervix uteri is not in all cases contra-indicated during pregnancy, and that abortion or sterility owing their origin to endometritis or endocervicitis may be successfully treated in this manner. He adds a caution, that in no case is the application to be carried quite up to, and, *à fortiori*, not through the inner os. In his opinion, cases of chronic endometritis may be cured by applications confined to the cervix. The reason of this appears to Dr. Gervis to be that returning health is just as capable of spreading by continuity of tissue as disease is known to spread.

(To be continued.)

Medico-Parliamentary.

SYPHILITIC INOCULATION BY EXPERIMENT WITH VACCINE.

In the House of Commons on Thursday last, Sir L. PLAYFAIR asked the President of the Local Government Board whether it was true that one of the Board's officers, in the course of an investigation into the conditions under which syphilis could be transmitted in the act of vaccination, had infected himself, and had seriously injured his health; and whether the conditions under which he succeeded in infecting himself were such as might occur during legitimate operations of vaccination?

Sir C. DILKE replied that the facts were substantially as stated in the first part of the question. The officer referred to, believing that this disease, although it had very rarely indeed been communicated in any of the operations of vaccination, nevertheless could, under some circumstances, be so communicated, was desirous of

blood of a healthy pig, ascertained by the "thread test" that it was practically free from uric acid, and then proceeded to add to it a concentrated solution of urate of ammonium. The serum was thereupon allowed to remain a short time at the temperature of the body, and subsequently dried on glass and sealed off. On searching for uric acid, it was separated easily in the crystalline form, not, however, as it had been added to the blood-serum as urate of ammonium, but as urate of sodium. All difficulty, therefore, as to the explanation of the change in the salt as it passes from the kidney cells into the blood is at once removed, and it necessarily follows that the tissue deposits which occur in disease must be composed of urate of sodium.

It may, however, be asserted that uric acid exists in the urine of man chiefly as urate of sodium, not as the ammonia salt, and that I have only assumed that it exists as urate of ammonium in the kidney cells. The former of these assertions is doubtless true with regard to the urine of man and the carnivorous mammal. With reference to the latter, I must still ask that the truth of my assumption may be taken on faith for a short time, until I have an opportunity of proving it.

The explanation of the presence of urate of sodium in the urine is most simple, for urate of ammonium, excreted, as it is, in small quantities by man, meets at once with large amounts both of phosphate and chloride of sodium, and with mere traces of any ammonia salt. Hence the same change ensues as when urate of ammonium is dissolved in blood-serum, and it becomes converted almost entirely into urate of sodium. I have made many observations tending to elucidate this subject. If healthy human urine, dense in character, but not giving any deposit on cooling, has a hot, concentrated solution of urate of ammonium added to it, it frequently throws down a copious precipitate on being kept in the cold. This I have found to consist mainly of urate of sodium, thus showing that a similar change ensues whether the ammonia salt is absorbed into the blood, or is sent forwards and united with the other constituents of the urinary excretion.

As I have already said, those who consider that uric acid is formed before it reaches the kidneys, usually look to some other organ as its source, the spleen having been often fixed upon. On this subject, Dr. Michael Foster makes the following remark, in his work on *Physiology*: "The constant presence of uric acid is remarkable, especially since it has been found, even in the spleen of animals, such as the herbivora, whose urine contains none." And again, he says: "No less suggestive is the fact that the increase of uric acid during ague and during ordinary pyrexia seems to run parallel to the turgescence, and therefore, presumably, the activity of the spleen." As I had never examined the spleen for the presence of uric acid, I made the following experiment:—

One thousand grains of the spleen of the ox, and the same amount of the spleens of the turkey and common fowl were dried in a water-bath and reduced to powder. This was afterwards treated with distilled water, first made alkaline with carbonate of sodium, and afterwards dialysed for two or three days into distilled water. The dialysed fluid was then evaporated to a syrupy consistence. A drop of that obtained from the ox was strongly acidified with nitric acid, and evaporated to dryness; a very distinct colour from the production of murexide was obtained, which became intensified by the action of the vapour of ammonia. When the same syrupy fluid was acidified by the acetic acid, and a few drops allowed to dry spontaneously on glass, distinct evidence was obtained of the presence of uric acid crystals, which became unmistakable when polarised light was employed. On treating the concentrated fluids obtained from the birds in the same way—viz., for the production of murexide and for the crystals, it was with the greatest difficulty that any indication of the presence of uric acid could be

detected by either test. These experiments were repeated, and with the same results. Unless the process of dialysis be employed, the uric acid is much masked by a peculiar matter which accompanies it in its solutions. This is at least partially got rid of by dialysis.

If the spleen be the organ in which uric acid is formed, why should not this acid be present in the urine of herbivorous as well as carnivorous mammals? On the same assumption, should we not expect that uric acid would exist in much larger quantities in the spleen of animals whose urinary excretion consists mainly of that principle, than in others whose urine is often devoid of it? As far as my experiments go, the very reverse is the case; for, while uric acid was easily detected in the spleen of the ox, in that of the bird it was most difficult to discover it.

Again, it would naturally be expected that in animals that throw out uric acid, the spleen would be larger, proportionally, than in others; but I am not aware that such is the case. It must also be remembered that uric acid has been asserted by different observers to be present in other organs besides the spleen, as the liver, lymphatic glands, and brain; and from this last W. Müller separated about 1 part of uric acid in 40,000 parts of weight, yet no one would consider that the production of uric acid is one of the functions of the brain.

Assuming that our second view is correct, and that the kidneys are the true formative organs, then an explanation of the presence of uric acid in the spleen, liver, and other parts is not difficult. When, from any cause, there is an appreciable back flow of uric acid from the renal organs, and resorption, then the blood becomes more or less impregnated with that principle, as we find to be the case in disease; and, under these circumstances, it is attracted by various tissues, and becomes united with them. That such attraction or elective affinity does exist for certain poisons I have full proof in a case of arsenical poisoning which came under my care in the hospital about twenty-five years ago. A young man had swallowed a dessert-spoonful of arsenious acid. As he survived this four days there was plenty of time for the poison to be absorbed. I embraced the opportunity of examining the principal organs of the body for arsenic, and found it in all parts, though in very different amounts. The liver appeared to be most rich in the metal, then the spleen and the skin. May it not be the case that, when uric acid exists in the blood, it is attracted differently by different organs, and thus the spleen and liver more frequently contain appreciable quantities than other tissues? Or again, may it not be that in some organs, as the spleen, the substance of which, if not acid during life, rapidly becomes so after death, while the blood remains strongly alkaline, the uric acid becomes less soluble, and more easily retained? Or yet again, may it not be that, being united to these organs, the uric acid escapes certain destructive influences to which, if it remained in the circulating fluid, it might be exposed?

Although I have been drawn, by the force of the arguments in its favour, into regarding the second view of the origin of uric acid as the more sound, yet I do not wish, even in my own mind, to become a partisan of any theory, desiring only to arrive at truth; and I have, therefore, endeavoured equally to seek out and discuss facts which are antagonistic to one or other view, with those which appear to favour it.

Before concluding this, the purely physiological part of our subject, I will state that there are a few facts which demand full explanation under any theory which claims to be accepted as the true one. For instance, the urine of the sucking calf, and of the young of other herbivora, contains uric acid in notable quantities, while that of the adult animal is usually free from it. How can this be reconciled with the view that uric acid is formed in the kidneys? There are also other facts closely allied to these which appear to be equally difficult of explanation by the second theory.

In the course of these lectures, I hope to be enabled

fully to solve these difficulties; and, in so doing, to bring before you many observations, the results of which may prove to be of great service and value, both in pathology and in therapeutics.

HELIGOLAND AS A "CLIMATIC" AND HYDRO-PATHIC STATION.

By Dr. C SCHWARZ, Colonial Physician.

AMONG the numerous health-resorts at which North Sea air and North Sea water are made use of as medicaments, Heligoland justly claims a pre-eminent position. Whilst offering, like other watering-places on the North Sea coast, all the requirements for cold and hot sea-bathing, combined with shower and steam baths, it has in addition a large covered swimming bath, so that sea-bathing can be had in all weathers, also promenades on a soil free from obnoxious exhalations, pure drinking-water, &c. It surpasses every other North Sea bathing place by the purity of its sea air. All the other watering-places are situated either along the coast or on islands, which during low water are scarcely detached from the coast, and are naturally to a greater or lesser extent exposed to land winds, and thus more or less resemble inland salt-bathing or hydropathic establishments.

Heligoland, however, situated as it is 25 to 30 miles from the nearest points of the Continent, is thereby completely removed beyond the deteriorating influence of land winds and the impure water of the coast, and may truly be termed a model North Sea bath: it thus offers not only all the conditions of a hydropathic station, but in a still higher degree those of a climatic health resort. The air of Heligoland, besides its density, is distinguished by the most perfect purity, by its high absolute and comparative constant hygrometric qualities, and the great quantity of ozone and sea-salt which it contains, whilst a further most salubrious influence is caused by the frequent strong breezes which the island from its position and small area cannot help receiving from all sides.

The climate is very unchangeable: the differences in the monthly temperature being very slight, sudden changes from one day to the other are very rare, and a change in the temperature between day and night is generally scarcely felt. The summer, therefore, is temperate and pleasantly refreshing, whilst autumn and winter are surprisingly mild.

The state of health and mortality of the inhabitants is most favourable, as a proof of which statement the following data collected from official records may be quoted:—

Out of 100 cases of death, there occurred in the following ages—

	In Heligoland from 1868-72.	In Prussia in 1877.
From 4—10 years of age	6·706	12·596
" 11—20 "	4·531	6·791
" 21—30 "	4·207	9·668
" 31—40 "	7·120	10·361
" 41—50 "	9·385	12·082
" 51—60 "	9·061	13·503
" 61—70 "	14·563	17·219
" 71—80 "	27·832	13·026
" Over 81 "	16·505	4·754

Contagious diseases, like measles, diphtheria, scarlet fever, whooping-cough, &c., seem never to appear spontaneously in the island, and have, when a case has been brought over from the Continent, never spread here.

The principal physiological influences of the sea air and sea baths of Heligoland on a healthy human frame consist in a tonic animation of the entire nervous system and an enormous rise in the organic change, during which latter the process of increase is much more considerable than the decrease, and therefore, notwithstanding a demonstrable great increase of the excretions, the weight of the body is visibly raised during a stay on the island. The indications for a cure in Heligoland result in part

from the above-mentioned effects on a healthy constitution, in part they are determined by long practical experience—not to mention such diseases as find their cure in other health resorts, or by special medical treatment. We find that the air and water of Heligoland offer a very valuable healing influence for many classes of disease, as nearly without exception truly brilliant results are achieved here, either by simply climatic cures or by the combination of climatic and hydro-therapeutic treatment.

1. In cases of general neurosis, of hypochondriasis, and hysteria, as also in a great number of local disturbances of the functions of the nervous system, above all, nervous dyspepsia and enteropathy (whether combined with persistent constipations or diarrhoea), and nervous interruptions of the male sexual functions.

2. In cases of general interruption of the organic change, caused by defective composition of the blood (anæmia and chlorosis), or by scrofulous and rachitic disposition and abdominal plethora.

3. In cases of hereditary constitutional debility and disposition to such diseases as result therefrom, scrofulous and tuberculous symptoms, want of resistance to rheumatic and other influences.

It is necessary strongly to point out that good results of a cure on Heligoland are, however, dependent on careful medical guidance, as also on a sufficiently long stay of the patient on the island. If the conviction of the eminent and incomparable sanitary value of North Sea air and North Sea baths in the above-enumerated cases has not as yet penetrated as much as might be desired into scientific and lay circles, it is because both the above conditions have been neglected, and finally Heligoland has been blamed for what only resulted from want of proper caution. Attention must further be drawn particularly to the circumstance that cases of hereditary debility, which give rise to a life of uninterrupted suffering, and against which medical treatment in general has proved powerless, are by no means effectually to be overcome by the stay of a few summer months on Heligoland. Such cases require an uninterrupted residence of a year or more.

It may be here remarked that, not only board and lodging are to be had during the winter months as well as in summer, but that also the education of children would not have to suffer, as the standard of the Colonial teachers is sufficiently high to answer any requirements.

The great attraction of Heligoland is undoubtedly the bathing, which takes place on the Düne Sandy Island, a long stretch of the finest conceivable sand without stones or pebbles, a mile from the main island (a high cliff of sandstone rising 140 feet from the sea), hence naturally and at all times of the tide free from any sewage or impurities so common in or near large coast towns and other sea-bathing resorts.

Regular communication with the Continent is kept up by steamers all the year round. In summer no less than twelve regular steamers ply weekly between Heligoland and the ports of Hamburg, Cuxhaven, and Bremerhaven (Bremen)—all ports in direct communication with England.

A good band, theatre, and other amusements are provided; while the inner man is well supplied at the numerous good hotels and restaurants. Boats of every kind, for fishing, shooting, parties, &c., also afford amusement. Hotels and lodging-houses, clean and comfortable, are available at prices to suit all purses, while the fact that Heligoland is a British colony, and that the islanders all more or less speak English is a further inducement to visitors from Great Britain.

A NUMBER of ladies and gentlemen assembled at Willis's Rooms on Friday last to celebrate the anniversary festival of the East London Hospital for Children, the Marquis of Lansdowne in the chair. Subscriptions were announced to the amount of over £800.

Clinical Records.

MIDDLESEX HOSPITAL.

Cases of Herniotomy.

Under Mr. H. J. MORRIS.

From notes by Mr. ROGER WILLIAMS, Surgical Registrar.

THE following four cases of hernia occurred in women of advanced age:—

Case I. was an inguinal hernia, and the operation was followed by excessive and continued diarrhoea. During the night after the operation the bowels were opened four times, by the 3rd day they had acted sixteen times, and by the 6th day twenty-nine times. For several days longer the bowels continued to act twice nearly every day.

I have seen death from the exhaustion due to diarrhoea after herniotomy, the patient dying within 48 hours.

In Cases I., II., and IV. the symptoms had existed, and went on increasing for several days before the operation.

In Cases III. and IV. the sac was removed after transfixing and tying the neck. The advantage of removing the body of the sac is, that the wound healed very quickly, and there is not the risk of reopening of the wound from nervous distension of the inflamed sac when left behind. This has often proved a source of delay in recovery; the skin round has healed rapidly and quietly, but a day or two later it has been broken open by the accumulation of inflammatory fluid secreted by the serous sac.

In the femoral region the sac is easily separated from its areolar tissue surroundings right up to the orural opening at which level its walls should be stitched together, and the body of the sac cut away.

The course of all these cases was uninterruptedly good, the temperature never rising above 99°6'. The dressings in all the cases were the same, terebene and oil on lint, and a pad of absorbent cotton wool over the lint. A drainage tube is in all cases used for the first 36 or 48 hours.

CASE I.—Strangulated inguinal hernia, R.—Excessive and continued diarrhoea after operation—Cured.

H. D., *æt.* 56, charwoman, married. This patient was admitted into the hospital with a strangulated inguinal hernia. Constipation had existed for 13 days. Sickness became fecal the day before admission. Tumour oval in shape, seated in inguinal region, and when thigh was strongly flexed could be seen to be plainly above Poupart's ligament; hard and dull on percussion. Patient was put under chloroform at 8 p.m., October 7th, and the tumour cut down upon and sac opened. The bulk was found to consist of highly congested omentum, which was matted together. There was a small knuckle of small bowel which seemed only slightly congested. The internal ring, at which strangulation was seated, was divided in three different parts—upwards, downwards, and to internal side. The omentum was transfixed and tied in three parts and cut off with scissors. Terebene, oil on lint, and absorbent cotton wool dressings applied to groin.

8th, 10 a.m.—Bowels have been open in the bed at four different times during the night. Evacuations of a darkish brown colour. Slept very well. No great amount of pain, and no sickness whatever. Had $\frac{1}{2}$ of morph. supp. last night. Tongue is dry but not furred. Brandy \mathfrak{z} j. every two hours.

9th.—Wound dressed, some sutures removed, and drainage-tube omitted. Bowels relaxed, frequent evacuations since operation. M. T. 99°, P. 102. E. T. 98°8', P. 98. Tr. opii \mathfrak{m} x., every four hours.

10th.—No nausea or vomiting since the operation. Tongue moist, thick, white fur, except at edges and tip. P. 104, small and weak. Bowels relaxed, two motions this morning. P. 102, F. 98°48'. Last night cough very troublesome. Not much sleep. No abdominal tenderness. Bowels moved sixteen times since operation.

11th.—T. 98°. Bowels open once. Milk diet, custard pudding. motions watery, contained small blood clots.

12th.—Bowels opened five times. No nausea or vomiting.

13th.—Bowels moved five times during night, very loose. P. 90, T. 97°25. Bowels purged again, making 29th time since operation. Brandy \mathfrak{z} ij. daily.

14th.—P. 96, T. 100°. Wound dressed. A little suppuration going on around sutures. Bowels opened twice since yesterday, motions firm, no blood. Took yesterday a little bread and butter. Is to have fish to-day. Milk and beef-tea. E. T. 99°4'.

16th.—T. 97°45. General condition improved. Bowels opened once yesterday, and twice in the night. E. T. 98°68'.

19th.—Bowels have been moved twice during the last 24 hours. Tongue clean, moist. Appetite good. P. 96, small, soft. Sleeps

well. No abdominal pain or tenderness. General condition good. Nov. 11th.—Discharged from hospital quite well.

CASE II.—Femoral hernia, L.—Herniotomy—Sac not opened—Recovery.

A. G., *æt.* 59. Patient has been ruptured for one year. First symptom of constipation came on Friday (29th). On Saturday (30th) she was sick; on Sunday there was hiccough; and on Monday she was relieved by enema and opium pill; though previous to this was advised admission into hospital, but refused. Yesterday, January 2nd, vomiting became distinctly fecal. There is a small tumour the size of a walnut in left groin; no impulse on coughing; not tense or tender.

Jan. 3rd, 1 p.m.—Operation for hernia. An incision along the inner side of the tumour; sac exposed; Gimbernat's ligament divided with herniotome passed along the index finger. Taxis was then applied and the contents of the sac slipped back upon slight pressure upon the bulk of the tumour, and a little kneading at the neck of the sac being applied. The sac, not being opened, was not ligatured or removed. Wound brought together with fishing-gut sutures (3), and dressed with terebene and cotton-wool.

Jan. 4th.—No vomiting since the operation. The pain she previously experienced is much relieved. The bowels have not been moved since the operation, but she has passed flatus. Last night slept fairly well. Nutritive enemata every six hours. Slight abdominal tenderness in the left iliac region. P. 104, full. Tongue rather dry, brownish white, and furred. General condition satisfactory.

5th.—Slept well. No abdominal pain, or vomiting, since the operation. Bowels confined, flatus passed. Tongue cleaning, moist; furred still in middle and at base. P. 100, less full than yesterday.

7th.—Wound dressed; sutures removed; soundly healed. A linear granulating surface along upper half of incision from anterior edges of skin not having been quite accurately adjusted.

8th.—Bowels opened this morning for first time since operation.

9th.—Bowels opened again in night. Patient well.

(To be continued.)

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND.

OBSTETRICAL SECTION.

THE Obstetrical Section met in the Hall of the King and Queen's College of Physicians, Dr. DENHAM, President, in the chair.

Dr. W. NEVILLE, Sectional Secretary, read the minutes of the previous meeting, which were confirmed.

THE THIRD STAGE OF LABOUR.

Dr. R. HENRY read a paper on the importance of the third stage of labour. He commenced by pointing out the various risks, immediate and remote, to which the improper performance of the third stage of labour exposed a woman. These risks would be minimised by a suitable conduction of this most important period of labour. To arrive at any just conclusion on this subject it was necessary in the first place to study Nature's methods in effecting the separation and delivery of the placenta and membranes—by the conjoint action of tonic and clonic contractions, moulding the placenta, as had been described by Dr. Matthews Duncan, or in the different way described by Schultze. In the author's experience, both these methods had been observed, a lateral attachment of the placenta being Duncan's, while a fundal, or nearly fundal one would give Schultze's. The former was the more common method. Dr. Henry quoted Deaman, Smellie, Collins, and others on the question of manual interference in the third stage. In 1786 Dr. Joseph Clarke had advised the practice of pursuing with a hand on the abdomen the fundus uteri in its contractions until the fetus be entirely expelled, and afterwards continuing for some time this pressure to keep the uterus, if possible, in a contracted state. This practice had been largely adopted in Dublin. Dr. Henry adhered to it, believing that in modern practice undue haste to press off the placenta was constantly exhibited. He kept his hand over the uterus during delivery and subsequently, but forbore pressing or actively supporting the uterus until it had itself commenced to contract clonically. Assistance should only be given with

the clonic contractions. A safe and permanent contraction following the expulsion of the secondaries might in this way be usually secured in from ten to twenty minutes. The chief error at present consisted in mistaking constant irritation for support of the uterus.

The PRESIDENT said the paper raised several questions of deep interest, as to the time at which the placenta should be removed, the danger on the one hand of being too precipitate, and on the other of leaving in the placenta too long; how far hæmorrhage was sometimes induced by a too speedy removal and at other times by leaving the placenta too long in the uterus, and also as to the danger of leaving in portions of the membranes.

Dr. HARLEY objected altogether to premature pressure over the fundus of the uterus for the purpose of pressing off the placenta. He also objected to exercising pressure on the cord at any period.

Dr. W. J. SMYLY stated that in the Strasbourg Hospital, where the patients were as a rule left to Nature during the third stage of labour, it had been observed that the placenta was most frequently expelled in the manner described by Schultze. He believed that Credé's method of exciting the uterus to contraction had been confounded with the hasty expulsion of the placenta. Credé himself never advocated the immediate expression of the placenta, but rather the immediate excitation of the uterus by irritation and friction through the abdominal walls, and then usually with the third or fourth contraction the expression of the afterbirth. The immediate expression of the placenta was very liable to be followed by the retention of the membranes and post-partum hæmorrhage.

Dr. MACAN said that since the time of Hippocrates there had been ebbs and flows of opinion as to whether expulsion of the placenta should be left entirely to Nature, or should be immediately effected by the accoucheur, either by passing the hand into the uterus, as the older authorities recommended, or by the more modern treatment of expression. Hence he thought that a happy mean between these two methods was probably the best way, for if the uterus was well contracted there need be no fear of hæmorrhage, and therefore no cause for hurry, while if the uterus was relaxed with hæmorrhage the removal of the placenta tended certainly to increase the hæmorrhage by removing all pressure from the mouths of the uterine sinuses, unless the means used to remove it at the same time caused the uterus to contract. The great advantage claimed at the present day by the adherents of the plan of leaving the whole process to Nature was that a much larger proportion of the decidua came away with the placenta than when the placenta was immediately removed. When two such authors as Dr. Matthews Duncan and Professor Schultze differed as to the mechanism of the separation and expulsion of the placenta, it was pretty certain that there was more than one way, and that both their views were probably right. If they adopted the expression plan, which might, he thought, be called "the Dublin Method," they should be careful not to allow the placenta to be suddenly expelled on to the bed, for a sudden strain was thus put on the membranes, and a portion might easily be torn off and left behind in the uterus. This had been looked on as a very serious accident, but he was inclined to think that the mere presence of a portion of the membranes in the uterus for some days after delivery could not be looked on as dangerous unless air had been allowed to enter and set up decomposition. He also thought that it was very often during the efforts made to remove a piece of retained membrane that the air was caused to enter the uterus. He had often seen a piece of the membrane expelled some days after the delivery without being accompanied with the slightest fever, or giving rise to the least fever; indeed, it seemed to him probable that in hospital practice at least the danger from retention of a portion of the membrane was less than the danger of infection from the hands of the operator in his efforts to remove it. He always waited a quarter of an hour before attempting to press off the placenta, and considered that light friction over the fundus with the tips of the fingers was a much more powerful method of inducing contraction than merely holding the fundus in the hands.

Dr. NEVILLE having also spoken,

Dr. R. HENRY briefly replied; and

The Section adjourned.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

THE INTERNATIONAL MEDICAL CONGRESS.

At the usual monthly meeting of this Society, held on Friday, the 4th inst., Dr. E. HART VINEY in the Chair, Dr. THUDICHUM, who had attended the recent International Medical Congress at Wiesbaden, stated that that body had met with a view of advancing medicine to the level of the natural sciences. The question of the extermination of infectious disease was fully discussed, but no new theory of particular value was advanced. Naturally, in a city where there were continual experiments in chemistry on a large scale—in the chemical factory in that city thirty professors confined their attention to theoretical chemistry—great attention was paid to the action of medicines on the human system. It was acknowledged that the chemistry of the body was badly understood, and that definite results from the action of medicinal agents could not be looked for at present. A clinical professor from Berlin gave an interesting account of the result in 40 cases of the treatment of tuberculosis with corrosive bichloride of mercury by means of the syringe, but although benefit was said to have been derived by some of the patients, he regarded phthisis as being left where it was, and could not recommend its adoption. In some of the German hospitals he found that tubercular disease of the lungs was being treated surgically. A rib was excised, and with every antiseptic precaution the diseased portion removed. Patients so treated had recovered in some cases. He hoped to continue his remarks at a future meeting.

Dr. BRUCE CLARKE read a paper on

THE PRACTICE OF THE BONESSETTER,

In which, after briefly alluding to the variety of cases that found their way to the bonesetter, and derived benefit from his treatment, he alluded to the pathology of stiff joints, and showed from observations of severe cases which he had been able to examine after removal of the limb, that adhesions were usually found outside joints and tendon sheaths, and were due to contractions of the limb. Adhesions were rarely found inside the tendon sheaths or joints. When they were the disease was far more serious, and rarely yielded to treatment. In cases of old stiff joints, the skin, and probably the subcutaneous tissues, became weakened and atrophied by disease, and were so rendered more liable to injury—in proof of which he cited several examples of tearing and laceration of the skin without the employment of undue violence. The usual history of the class of cases that came under the hands of the bonesetter was this: The patient met with an injury resulting in a dislocation or fracture, or perhaps, only a severe bruise or sprain. He readily recovered up to a certain point, but when an inflammation had subsided, there remained a stiffness accompanied by pain on movement. In other cases there were periodical attacks of synovitis. The treatment in all such cases was active movement with or without chloroform, which was usually accompanied by a click or crack, ascribed by the bonesetter to the replacement of the bone, but which was due to the freeing of the corrective tissue bands. In slight cases one violent flexion might cure the trouble of months. In severe cases the treatment would be measured by months rather than minutes. The pathology of such cases was as well marked as that of iritis; when there was the advantage of seeing the adhesions not only form, but rupture and disappear. He expressed his obligation to Mr. Wharton Hood's lecture, which had induced him to study this subject. The difficulty with these cases was the selection of time for rupture. Signs of inflammation were their guide in that matter. Rest should be relegated to its proper position in surgery, and should not be kept up when it increased instead of abating the patient's troubles.

Mr. KEETLEY thought Mr. Clarke could hardly have chosen a more interesting subject. Undoubtedly, the bonesetter frequently earned great credit by the manipulations which broke down adhesions outside a joint, and at the same time removed the cause of inflammation; for in these cases there was no contraction of membrane. Where there was an osseous fibroid band, the case was of strumous origin—it was due to the presence of organisms. In such cases the joints became adhered, and there was great danger from the rough usage of the bonesetter. In the treatment of such joints he had put on ice for several days with great advantage, and had repeatedly put them straight. When once

convalescent, a joint rarely again became strumous. There was much bewilderment with regard to the value of rest, which was only a negative factor. It was the natural tendency of a colony of germs to die as the joint became healthy.

Dr. ALDERSON related the case of a knee which became enlarged fourteen days after confinement, but without pain. He called on Dr. Hewitt, who ordered rest, the knee to be rubbed with salad oil. He also used Scot's dressing. Subsequently, at Brighton, a seaweed poultice was used. The treatment was successful. He had also known an enlarged ankle which was caused by the use of lotion and embrocation, proving that there was no fracture.

Dr. ALDEN OWLES had seen several cases confirmatory of the opinions advanced in the paper. One was a shoulder, the manipulation of which caused agony to the patient, but in which motion was regained. Another, regarded at first as a strumous joint was eventually cured by somewhat violent manipulation.

Dr. Viner referred to the case of an officer of the 60th regiment, who sustained a compound fracture below the knee whilst playing at football in India. The bones were set by some naval surgeons who were watching the game, but in consequence of the leg being deformed the adhesions were broken, and the limb was re-set. The ankle then remained fixed, and the patient's health suffered. However, Mr. Erichsen was called in, he broke the adhesions, and the patient recovered so thoroughly that he was enabled to rejoin his battalion in the Transvaal.

Dr. BRUCE CLARKE, in reply, pointed out the necessity of distinguishing chronic cases, as such were usually made worse by movement.

THE UNQUALIFIED ASSISTANT SYSTEM AND THE ILLEGAL SIGNING OF DEATH CERTIFICATES.

(Continued from page 492.)

THE RISE AND PROGRESS OF THE SYSTEM OF EMPLOYING ASSISTANTS.—(Continued.)

In his introductory lecture at St. Thomas's Hospital in 1873, Dr. J. Harley suggested the attaching to each hospital an out-patient department, which might take charge of patients too ill to come out, and precluded by the nature of the disease, or other circumstances, from admission to the wards, and who might be seen at home by students in their last year, after lectures, &c., had been fully attended. Superintendence by the seniors of the staff is implied. (a)

This is quoted not from its having been taken into separate consideration, but as showing how important this part of training is considered by those interested in medical schools.

Dr. Theodore Acland, M.B. Oxon, writes: "There seems to be no doubt that much valuable experience might be gained by those who are about to enter practice, if they were compelled to hold a resident appointment in some hospital recognised by the examining boards; or, failing this, to occupy the post of assistant to some registered practitioner, after having obtained a diploma, but before being allowed to place their names on the Register."

Mr. Marcus Beck, in his introductory address at University College Hospital this year, recommending his pupils to study with a dispensing practitioner as a sequel to hospital work, thinks that "six months of such experience would be quite sufficient."

Dr. Redwood, of Rhymney, county Durham, writes: "It would undoubtedly be a great boon to medical men, and a decided benefit to themselves, if candidates were required, after passing the qualifying examination and before being registered, to act as assistants for six months at least. They would then not only be better able to prescribe, attend casualties, &c., but would have some practical knowledge of, and be more handy at dispensing, besides being more neat and methodical in their work altogether. I have found some assistants very deficient in these respects."

Dr. Leech, of Owens College, is of opinion that "education

for general practice is not complete unless a man has worked under a general practitioner."

There seems to be no doubt in the minds of teachers, pupils, and practitioners, who communicate their views, that in addition to the systematic school teaching, a young man should go through a certain probation, involving partial charge of patients, before he enters on independent practice. It would be very desirable to give to all that which the wisest teachers recommend to their most industrious friends, who in point of fact least of all need it. If it is of use to the cultured and intelligent, of how much more use might it be to the average student, of how much more to those whom John Milton calls "the stocks and stubs" of the school, who are trembling on the verge of becoming burdensome or profitable to the community, and for whom the scale inclines one way or the other, according to the mode in which they pass the first few months after the final examination. What appears to be desired is something equivalent to the "title for orders" in the English Church; that is to say, service as a curate for a certain time after examination, but before full ordination to professional work, which service is required of every secular priest. The plan is found to operate satisfactorily, and, although troublesome to some candidates, has not been complained of as a hardship.

There really is no valid reason against requiring a candidate for registration to spend at least six months after final examination, but before being registered, as assistant to a registered practitioner recognised by an examining board, or in some equivalent public post where he would be under supervision.

And the suggestion that this end should be obtained by the licensing body keeping the issue of the diploma in abeyance till the assistantship shall have been served, is well worthy of consideration.

The period of assistantship before registration would be a good time for that attendance upon pregnant women which is required of candidates by nearly all the licensing bodies in the kingdom.

It is obvious that hospital students, who before their final examination give obstetric aid, do so as unqualified assistants. Their employment in that capacity is open to objection, and occasionally leads to serious evils, and to dissatisfaction among the tens of thousands (a) annually trusted in the hands of these students. It is also an inconvenience, to say the least, to the school staffs; and is found to be "the portion of the course of instruction which is, practically, by far the most difficult to carry out," as Dr. Arthur Farre informed the Council in 1869. (b)

Nevertheless, the greatest objection to this abuse in the eyes of a Council of Education will probably be that it so completely occupies the body and the mind of the student as to be a serious interruption to other engagements. Dr. Norman Moore finds at St. Bartholomew's that attendance on women in labour "makes most men for the time quite unfit for any other occupation."

The question naturally arises whether enforced attendance on women during their confinements, or even in labour, is, as a means of gynecological education, worth the sacrifices it entails. It would hardly appear to be so; for as a matter of fact, training for midwifery with charge of women and infants does not so readily fit a man to show himself competent for practice as training for medicine without charge of patients. At the London College of Physicians, there have been rejected from the examination for licence during twenty years, 367; on the score of medicine alone, 62; on the score of midwifery alone, 109; on the score of both together, 136; leaving a balance of 75 per cent. against the midwifery. Previous to this examination, attendance on twenty labours is required.

In Scotland, where six is the number required, there does not appear to have been observed any notable difference between the numbers of rejections on the score of midwifery and of other subjects. In fact, at Edinburgh, according to the report of Dr. Simpson, none have failed in midwifery who have not failed in other subjects also. It is noticed, however, by a late examiner at Glasgow, that candidates who have come up chiefly from English provincial schools (which are largely frequented by unqualified assistants employed in attending pregnant women and their offspring) were "shockingly ignorant of midwifery."

(a) Germans call this course of study "Poliklinik"; probably some such term as "Home-rounds" or "Home-visiting" would be more agreeable to English ears. It would of course rank as an assistantship.

(a) If an average of twenty labours is required for each candidate for diploma, the 1000 who pass the examination have had 40,000 infants and women in their charge.

(b) See Report of the Committee on Professional Education, p. 217.

That there exists an unexpressed want of confidence in the desirability of attempting to instruct pupils by employing them prematurely in work, is shown by the great diversity in the numbers of accouchements required at the several examining boards to have been conducted by the candidate. At the King's and Queen's College of Physicians, and at the College of Surgeons of Dublin, it is thirty; at the College of Physicians in London, it is twenty; at the Queen's University, Ireland, it is ten; at Edinburgh, Aberdeen, and Glasgow, it is six; at the German Students' Examination it is four; at the University of Oxford it is none.

Independently of all evidence derived from experience, it might have been expected that, during the period devoted to the acquisition of knowledge, to call upon the pupil to exercise that knowledge as if it were complete, would check its further development. It stunts the growth of the mind, just as too early toil stunts the growth of the body, and leads a young man to think his education accomplished, and that he is already furnished with all the requisites for practical life.

There is not the same want of confidence in the other means of education, such as definite courses of lectures, clinical instruction, and preliminary studies, the quantity of which called for by each licensing body varies very little indeed.

It must be always remembered that the taking charge of these patients of the obstetric department is enforced solely as a *means of education*; for it is not supervised by an examiner, which must be done where it is made a *test of efficiency*, as in the German Staats-examen. In the last-named examination the "necessary operations," in one selected instance, have to be "performed under the eye of an examiner," and a written report of the progress of the case for nine days handed in for inspection. (a)

(To be continued.)

Special.

THE NATIONAL HEALTH SOCIETY'S EXHIBITION.

POPULARISATION of reforming habits has by common consent become a legitimate part of society work, and not a few of modern associations have been founded with a view to carrying out reforms having for their object the general welfare of the people: Such unselfish labour is eminently praiseworthy, and deserves to receive every kind of encouragement that can properly be given to it; for, although a good many hobbies are ridden, at times to a desperate extent even, by more enthusiastic supporters of such societies, still the aggregate good they accomplish suffices to bury far out of sight such harmless indiscretions as are sometimes committed by too zealous reformers. Especially may this be said in connection with the National Health Society, which, although it is sometimes committed to seeming absurdity by its members, is nevertheless slowly accomplishing valuable work by popularising at least the consideration of domestic and personal hygiene. Little soever as it may be, every little done in this direction is so much absolute gain in a national sense, that the amount of interest taken in the exhibition of hygienic dress, sanitary appliances, &c., now on view at Humphrey's Hall, Knightsbridge, is an excellent indication of advancing opinion on subjects of importance to the home and the individual, both hitherto too lightly regarded.

The Exhibition is not an extensive one, but it is sufficiently representative to be well worthy a visit of inspection. Prominence is of course given to "the dress of the future," several stalls being set apart for the display of garments cut in the approved form advocated by Lady Harberton and her disciples. Here and there, too, in the building may be seen living wearers of the much-derided costume, and certainly as a mere matter of elegance and beauty, the unreformed eye finds difficulty in admitting the superiority of appearance possessed by the hygienic costume, however ready the observer may be to admit its

unquestionably greater healthfulness. Possibly, by-and-by, when the new dress is universally or very generally worn, the absence of contrast will lead to the evolution of more accurate notions of the beautiful in the masculine mind; and then in all probability we shall unanimously despise our own distempered judgments, which lead us now to look more favourably on the shapely dress than on the shapeless costume which hangs on those who exhibit it in use at the Exhibition.

A prominent position facing the entrance way is occupied by a stall filled with a large collection, of drugs, &c., exhibited by the well-known firm of Burroughs, Wellcome, & Co. Among the novelties to be found on this stand (Block B.), the most recently introduced improvements in pharmacy are "the Burroughs elixoids." These comprise an elegant and agreeable series of liquid medicines in the production of which, success has been carried to a very high degree of perfection; the process of preparation having effectually disguised the taste of a number of drugs, against the administration of which their unpalatableness is often a serious objection. Bromides of potassium and sodium, colisaya bark, iodide of potassium, and biniodide of mercury, and a number of other remedies and combinations are offered in this improved shape, which is unquestionably a very great advance on the older forms. Messrs. Burroughs & Wellcome show also a most deliciously fragrant perfume, to which the appropriate name of "edenia" has been given, and which, for purity and exquisite odour, is altogether matchless. It has a most refreshing effect moreover, and for the use of delicate invalids it is likely to become a favourite scent. Compressed tablets of potassium permanganate, each containing two grains, have been added to the familiar "Wyeth" series, and will be found of much service for general internal use, and in many affections of the mouth and teeth; this form of the drug, moreover, admits of ready and convenient employment under any circumstances. "Hazeline, Florida Water," MacKesson & Robbins' capsuled pills, and other well-known specialities for which the house of Burroughs & Wellcome is famous, are also shown, but need not be further mentioned here.

At the opposite end of the hall to that occupied by Messrs. Burroughs and Wellcome's stall will be found that of Messrs. P. and P. W. Squire (No. 53), who show several novelties that are worthy of more than passing attention. Among these a recently added improvement to the well-known medicine chests manufactured by this firm calls for especial notice. This ingenious arrangement consists in a patent spring lid, by means of which the stoppers of bottles contained in the case are, when it is closed, kept securely in place, thus obviating the necessity of fastening them by means of a cover or cap. Such a contrivance has long been a desideratum, and the provision of it will be a most useful addition to many a hard-working practitioner; for the invention can be applied to cases of any size, and for all purposes. Messrs. Squire have also introduced a new malt extract, termed by them "superdiastatic," and which, it is claimed, possesses unusual digestive powers. It is certainly a most pleasant and palatable form of extract, and will doubtless be very favourably received by the profession. Among the elegant preparations exhibited on the stall none are more interesting than those in which the antiseptic agents, eucalyptics and thymol are presented; and particular mention must be made of the toilet requisites into the composition of which these valuable agents enter. The soap tablets are very agreeable and healthful. Several forms of lozenges also are shown, among them those containing eucalyptics; and a cheap but efficient respirator made for hospital use deserves notice.

So much favourable notice has already been given to the Maltine Manufacturing Company's speciality, and the preparation is so universally recognised as an invaluable therapeutic agent, that little more than mention of the fact that it is shown in the exhibition need be said concerning it. We must, however, refer to another important

(a) Beigel and Bruce. Report on Prof. Education. 1869.

article introduced by the same firm, and which, as "Reed and Carnrick's Beef Peptonoids," have within a short time won the unanimous approval of those who have employed them. These peptonoids consist of concentrated powdered beef extract, *partially digested*, and in combination with gluten in equal amount. For economy and palatableness this preparation is unrivalled, while also it is a valuable clinical assistant. We hope soon to publish reports of the experience gained after extended trial of the peptonoids in cases of disease.

Messrs. Allen and Hanburys' stall contains samples of most of the "well-known A. & H." preparations, among them the "tasteless" castor oil, "perfected" cod-liver oil, &c., by the introduction of which they have achieved a well-deserved reputation. The "A. & H." malt extract and farinaceous foods also demand attention.

An important collection of the preparations of natural digestive ferments with which Mr. Bengel's name will always be inseparably connected is shown on Stand 7. The already widely known and appreciated "liquor pancreaticus," and "liquor pepticus," with the "peptonised beef jelly," and "self digestive food," are all exhibited; and it is highly probable that every medical man who visits the exhibition will mentally reflect on the advantages derived in his own practice from the admirable and effective assistance lent to his efforts by the results of Mr. Bengel's long-continued labours. Certain it is that few modern improvements in pharmacy have done so much as Bengel's preparations to assist the physician in his treatment of the sick; and it is in the highest degree satisfactory to learn that steady progress is being made, not only in the direction of perfecting these invaluable remedial agents, but also in the extent to which they are appreciated and employed.

In the way of creature comforts pure and simple the exhibition is fairly well supplied, among the evidences that hygienic principles extend even to material blessings being the array of wines and other liquors of the kind that cheer and even inebriate if too freely indulged in. In this respect, however, the samples exhibited by the Australian Wine Company (Stand 28) might well tempt the most careful to somewhat unusual "tasting;" for some of the brands introduced from the Antipodes compare even more than favourably with European wines of similar class. It is easy to comprehend, after once making trial of them, why public taste is rapidly approving these newly-introduced vintages, for they possess a wholesomeness and agreeableness which can be the accompaniment of purity and quality alone. Added to their excellent qualities the comparatively low price at which the wines of Australia are put on the market must inevitably tend to bring them very generally in demand among those who regard the properties rather than the source of their wines. The "Muscat" sold by the Australian Wine Company at 42s., and the Hermitage at 36s., a dozen is, altogether apart from its price, one of the choicest liquors we have ever tasted; and many of the cheaper white Australian wines are infinitely superior to much of the expensively-rated produce of Continental vineyards sent to the English market.

Mr. James L. Denman shows a selection of pure Greek wines, which also deserve the careful attention of connoisseurs. Reasonable in price, choice in flavour, and of guaranteed purity, there is every reason why these, like the Australian growths just noticed, should be admitted to replace the deteriorated vintages of France and Germany. We would especially recommend trial to be made of the "St. Elie" (white), "Como" (red), "Noussa" (red), Greek wines.

The exhibition includes a large number of other objects to which we should, if space permitted, willingly draw attention. "Mellin's Infants' Food," "Feltos's Lime Juice," "Maignen's Filtre Rapide," "Cleaver's Terebene Preparations and Soaps," improved cowl, water-closets, ventilators, &c., &c., all deserve attention, and the visitor will do well to spend some time in examining them.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 13, 1883.

LORD MORLEY'S COMMITTEE.

(Second Notice.)

A FURTHER perusal of this very voluminous report of 771 pages gives us an insight into the prevailing opinions of the military and medical chiefs of the Army on Army medical organisation. His Royal Highness the Commander-in-Chief considers that young medical officers would best learn discipline by being attached for at least three, and if possible, five years to a regiment; while all the senior medical officers concur in the necessity for the re-introduction of the examination for promotion. Professor Longmore's evidence upon this point must carry the greatest weight. He tells the Committee that in the German service—in consequence of finding the necessity for it in the Franco-German war—the following, among other regulations, were issued to ensure that medical officers kept up their knowledge. He has to go through a three-fold examination. He has first to write an essay on a subject that is sent to him from the war office; next he is subjected to an oral examination and a practical examination as follows, viz., three important surgical operations: 1. An amputation; 2. Ligature of one of the intricate arteries; 3. The resection of a joint. If he fails in the performance of one of these he may select for himself another of a corresponding kind. If he fails and is allowed

no other examination, his promotion is stopped for all time. He must be also well acquainted with the field equipment. Surgeon-General MacKinnon considers that the promotion of medical officers should depend to a great extent upon the manner in which they taught the orderlies their nursing duties. Both officers strongly insist that the supreme control of an hospital should rest with the senior medical officer in charge. Surgeon-General Hanbury's suggestions that the Brigade should be the unit for the field hospital, that sections of the bearer companies should be attached to it, and that each regiment should have an hospital tent, two panniers, a non-commissioned officer and private under the brigade surgeon, have been adopted by the Committee. Some important movements do not appear to have been communicated to the principal medical officer and some medical orders were issued without his knowledge by the military authorities in Egypt—such as appointing two medical officers to each regiment on the field—which, if they had been carried out, would have deranged the whole of his medical arrangements. With regard to the statements made in various newspaper Sir Garnet Wolseley telegraphed to the Director-General of the Army Medical Department, dated, Abdin, 30th September, 1882, "The medical department is working to my entire satisfaction." The medical officers' evidence support this statement, as does that of Sir Garnet Wolseley's Chief of the Staff. Under these circumstances further comment is unnecessary. The greater number of the combatant officers desire the presence of a surgeon with their regiments, and consider his presence would be an advantage as preventing malingering on the part of soldiers. The roster constantly creeps up as the difficulty. In reply to a question from Dr. Crawford, noticing the fact that there are only seven brigade surgeons under 48 years of age, Mr. Longmore states his opinion that with such slow promotion it is impossible to have young and efficient administrative officers in the department, or that they can be expected to take much interest in supervising the study of the younger officers. Space will not permit any further reference to a report which we commend to the perusal of all military surgeons.

THE ANNUAL MEETING OF THE IRISH COLLEGE OF SURGEONS.

THE proceedings of the annual assembly of the Fellows, of which we gave a brief report last week, are of such interest as to deserve more extended criticism. The number of Fellows who assembled was not especially large, but nevertheless the meeting was the most interesting which has taken place for some years, and, for the first time in the Collegiate record (as we believe) so much business was to be transacted that it became necessary to adjourn the College over to Monday the 4th, and carry on the debate concurrently with the ballot. The result of this arrangement was eminently unsatisfactory, and, if similar circumstances again arise, we hope some means can be devised to have the business discussed calmly and in order. On this occasion the debate was so much disturbed by the ballot that several motions of the highest importance were decided, after a perfunctory conversation, by a knot of the Fellows standing around

the President's chair. The first motion submitted was that referring to

ELECTIONS BY LOT.

Dr. Thornley Stoker moved "that in the opinion of this College the present method of electing professors and examiners is unsatisfactory, and that the Council be recommended to seek for such alterations in the charter as shall enable these elections to be made by the vote of the entire Council, or such part of it as may be present; not less than two-thirds of the whole number, including the President or Vice-President, to constitute a quorum for election purposes."

There was no disputing the proposition that an election of important functionaries by a method in which chance largely enters ought to be discontinued, and the College concurred in that view.

The other proposition which was expected to be moved *i.e.*, That Professors and Lecturers should be eligible as examiners was not touched, probably because of the anticipation that it would be resisted by private school teachers generally, under the idea that Professors in the School of the College would be preferred for examinership if the exclusion which the charter now provides for were removed. For this apprehension there does not seem to be the least ground, the lecturers in private schools being many times more numerous than the College professors, and their influence in the Council being at present quite equal. The College then proceeded to consider

THE SHAM CERTIFICATE QUESTION

Upon a motion by Dr. Jacob "That this College approves of the determination evinced by the Council to ensure *bond fide* of attendance on courses of medical study, but is of opinion that attendances purporting to be given by persons who are engaged during the usual hours of medical study in other engrossing avocations is not a *bond fide* fulfilment of the four years of study required by the General Medical Council, and therefore ought not to be recognised by this College as sufficient qualification for the Letters Testimonial of the College."

We have already summarised the debate on this subject and need not do more than point out that the motion was not—as its opponents represented it to be—a declaration against study at night, but was simply an assertion of the principle that a young man who was engaged all day in a shop or office did not devote, as required by the College and Medical Council, four years *bond fide* to the study of the profession. This assertion does not, in fact, admit of any dispute, for, although such a student may present to the College any number of certificate papers, he cannot pretend that he has conformed either to the spirit or the letter of the regulations. The motion was met by three successive amendments, none of them antagonistic to the principle of the resolution, and none of them favourable to night lecturing. Mr. Stoker, of the Ledwich School, moved, simply to remit the subject to the incoming Council. Dr. Corley moved

"That this Council recommends the *bond fide* observance of the rule of a four years course of study, or, in case of students who cannot give their whole time to their professional work, an equivalent in time and curriculum."

The objection to this resolution was obviously that it recognised the right of students who could not attend the regular medical studies in four years to make up the deficit by irregular studies for a longer period. This amendment was withdrawn, and Dr. Kidd then moved

"That the College, instead of passing any order at the present meeting regarding night lectures, request the incoming Council to forward a copy of the arrangements for securing the attendance of students at lectures and hospital to every lecturer and clinical teacher recognised by the Council with a request that they will aid in carrying out these arrangements."

On this amendment being moved, Mr. Stoker, of the Ledwich School, withdrew his frugal proposition to remit the subject to the incoming Council, and seconded it; and it was thereupon passed by a majority of 28 to 16, Dr. Jacob's motion being therefore superseded, and not put from the chair.

This narrative of what did really occur becomes necessary, in consequence of the publication in the newspapers of a totally untrue statement that Dr. Jacob's resolution against night lectures was negatived by a large majority of the Fellows. In fact, no resolution against night lectures was submitted, nor did the night lecture party venture to take the voice of the College which, they say, was in their favour, nor was the resolution against sham study (which they seem to consider applicable to night lecturing) voted upon by the Fellows.

Dr. Kidd's amendment, which was eventually adopted, could not be objected to by the opponents of sham study, except on the ground of its weakness. It was clearly the duty of the Council to circulate its certificate regulations, and it has already done so. If there is anything to be gained by a further circulation backed by an appeal to teachers to be honest in observance of the rules, by all means let the Council repeat the issue.

But we do not in the least believe in the efficacy of remonstrance against practices which are ingrained by long years of custom, and which have the additional charm of paying right well. The large majority of the Dublin teachers who would be likely to regard the appeal of the Council, have already, we believe, ceased from issuing fictitious certificates; the minority will not cease earning money in this way as long as those certificates are permitted to pass current. It is easy to comply in the letter with the suggestion of the College that a roll shall be called, and to evade the spirit of that suggestion by taking no care whether the name is answered for by the student himself or by a single student for half-a-dozen others; it is equally easy to fulfil the order by keeping an hospital attendance book, but to take no cognisance of the fact that the said book is signed at 9 a.m. by students who are hard at work in office or shop at 9.30.

The College has failed and will fail to make teachers honest by persuasion, and so long as it continues gravely to receive as genuine the proofs that a student who is in a place of business at a given period is also beside his hospital teacher at the same moment, so long will certificates that he is in both places at the same time be saleable and sold.

The next business of the Fellows was the following motion by Dr. Kidd, with reference to the Medical Bill:—

1. That the incoming Council be recommended to have the Medical Acts Amendment Bill further amended, so as to establish and maintain a closer supervision over medical education on the part of the College than the present Bill proposes to do.

That it appears to the College this could best be done

by defining in the Bill that all previous examinations should be conducted by the "medical authorities."

2. That the Board examination should be accepted by each of the medical authorities for the final examination.

3. That candidates who have passed the previous examinations of any medical authority and the final examination by the Board, should receive the qualifying diploma of such authority, and be registered in right thereof.

This motion, though heralded by a violent denunciation of the Medical Bill, was in no sense hostile to the measure, and, being a wise and sensible proposition for amendment, was at once accepted by the College and passed *nem. dis.*

(To be continued.)

EXECUTIONS AND THE PUBLIC PRESS.

WHEN, some years ago, the Home Office decided that for the future executions should be carried out in private instead of in public, as heretofore, most right-minded people experienced a sense of relief, from the thought that from that time the eye and the senses generally would be less offended by the parading of revolting details before the public. Such people were, however, disappointed. Since then a portion of the daily press has done its best to frustrate the wholesome intention of the Government. Every scrap of information, every disgusting little detail, that it has been able to collect respecting the horrors of an execution has been made public with an effusiveness and an unctuousness that savour very much of gloating, and mercenary gloating to boot. And these gentlemen are not satisfied that they are excluded from executions; they would fain be admitted, "if only to protect the interests of the public." Who wishes them "to protect the interests of the public?" Are not the public already efficiently represented by their duly authorised representatives—the sheriff, the chaplain, the gaol surgeon, the governor, and the warders? These are more trustworthy protectors of the "interests of the public" than irresponsible reporters, and less likely to offend the public by offensive details in the daily papers.

These thoughts are prompted by the remarks of our Scottish correspondent on the recent executions in Glasgow, and by a paragraph which appeared in the columns of a provincial daily. We give the paragraph (omitting names) exactly as it appeared, and leave it to our readers to judge for themselves whether they ever saw a piece of sillier (because bare-faced) special pleading:—

"The decision of the visiting justices . . . not to admit reporters to witness the execution of . . . will not improbably call greater attention than before to this somewhat delicate question. The balance of opinion appears to be that, without in any way wishing to encourage sensational writing upon such dismal affairs, the presence of reporters is desirable, if only to protect the interests of the public. Many a London journalist could, if he would, tell somewhat startling stories as to the bungles which at one time or another have marked the efforts of public executioners; and one of these functionaries was never allowed again to operate after a terrible blunder—seen by the reporters, and duly noted—which he perpetrated at Leeds some six years since. But what chance would there have been of this becoming known if the only witnesses had been those

personally interested in keeping it quiet? The present haphazard system of leaving the question of admitting reporters to the discretion of the high sheriff or the visiting justices is provocative of much friction, and might, in certain instances, prove a veritable premium upon bungling."

The question of money-making under the guise of philanthropy is always a "delicate" one. What the writer means by "balance of opinion" is, no doubt, the balance of his own opinion and of that of other reporters. That it is a fact that the balance of public opinion is in favour of private executions being made public for the benefit of reporters and their employers we indignantly deny. Even if public taste were so degraded, it would be the duty of the leaders of public opinion to elevate it, and not to pander to it by acting the part of procurers. If, however, these gentlemen honestly think themselves the protectors of the "interests of the public," and if they honestly believe that their presence at executions would really prevent this "veritable premium upon bungling," we see no objection to their fulfilment of a sacred duty, provided they are first sworn to spare the public a repetition of those degrading details to which they have been hitherto prone. One more part of the paragraph deserves notice—viz., that relating to the haphazard system of admitting reporters or not, according to the whim or discretion of the high sheriff or visiting justices. We would suggest that the haphazard system be improved away, and that the admission of reporters to executions be placed upon a satisfactory basis—i.e., that the Home Secretary take from the high sheriff and visiting justices the discretion of admission. "Much friction" would doubtless be avoided by this simple proceeding.

Notes on Current Topics.

Pleasant for Jack.

THE advocates of unrestrained infection have just enjoyed what will probably be to them a delightful proof of the wisdom which has animated them to pursue a course resulting in the virtual repeal of the Contagious Diseases Acts. In a letter to the *Daily Telegraph* on Friday last Dr. A. Conan Doyle, of Portsmouth, has given irrefutable evidence of the all too certain efficacy of the method which Mr. Stansfeld and his followers will by and bye receive the credit of having introduced, for national deterioration of physique. The following extract from Dr. Doyle's letter speaks volumes for the effect which that thrice ill-advised motion in the House of Commons is producing:—"Last week a large transport entered Portsmouth Harbour with time expired men from India. Upon the same day thirty diseased women left the hospital with the avowed intention of meeting that transport, and there was no law to prevent it." Divested of all additional details this bare statement of a fact contains a more crushing exposure of the fatuous proceeding of sentimentalists than the most eloquent exposition of the evils to which society is exposed to by their wretched meddling with questions involving scientific considerations.

Dr. Doyle's comments on the action of the Contagious Diseases Acts opponents are, however, well worthy of

reproduction. He continues:—"I say that, if an unfortunate soldier coming home to his native land after an absence of years, and exposed to such temptation should yield to them, and entail disease upon himself and his offspring, the chief fault should not lay at his door. It surely emanates logically from those enlightened legislators who set loose those thirty bearers of contagion, and their like, upon society. For fear delicacy should be offended where no touch of delicacy exists, dreadful evils are to result, men to suffer, children to die, and pure women to inherit unspeakable evils. Loose statements and vague doctrines of morality may impose upon hasty thinkers, but surely when the thing is reduced to its simplest terms, it becomes a matter of public calamity that these Acts should be suspended for a single day, far more for an indefinite period. The apostles of free-trade in infection have worked to such good purpose that within a few weeks the streets of our naval stations have become pandemonia, and immorality is rampant and self-assertive where it lately feared to show its face. Property has much depreciated near our public houses since the suspension of the Acts on account of the course of vile women, whose uproar and bad language make night hideous. I venture to say that, were the old laws enforced again to-morrow, there would still in a hundred years time be many living who could trace inherited mental or physical deformity to the fatal interregnum which the champions of the modesty of harlots had brought on." Other places than Portsmouth tell the same tale, as witness the following resolution of the Dover Town Council, a copy of which has been forwarded to the Home Secretary—"The Dover Town Council views with deep regret the suspension of the Contagious Diseases Acts, and trusts that their full operation may be reinstated at an early date."

Careless Patronage.

MUCH regret will be experienced at the announcement now being made public, that the President of the Royal College of Surgeons, Sir Spencer Wells, Bart., has permitted his name to be used in connection with an institution that is at least regarded by many members of the profession with suspicion. We refer to the St. John's Hospital for Skin Diseases, in Leicester Square, the management of which has been very unfavourably commented on in the past, and in aid of which a bazaar is about to be held under the patronage and in the presence of, among others, the eminent surgeon named above. Such a proceeding on the part of Sir Spencer Wells, is somewhat unfortunate, for it necessarily commits the distinguished College he so worthily represents to approval of a special hospital, the best that can be said about which is that it occupies a position of questionable stability; and we cannot refrain from an expression of very sincere regret at the association of a leader of English surgery with an institution which fails to command universal respect and sympathy.

THE President of the Royal College of Surgeons of London—Sir Spencer Wells—has issued cards of invitation to a *conversazione* at the College, at nine p.m., on Wednesday, June 20th.

The Dublin Sham Certificate Trade.

STIMULATED, probably, by the agitation against fictitious certificates which has been growing in strength for the last two years, the Board of the University of Dublin has issued the following notice:—

NOTICE is hereby given that, in future, Students in Arts of Trinity College, who have entered the Medical School during or since 1880, will not be required to produce certificates of attendance on lectures previous to admission to the Medical Examinations, but will be required, instead, to fill up, and lodge with the Medical Registrar, forms of Notice which will be issued before each examination. There will, therefore, be no general issue of Certificates by the Professors; but those students who may require them for presentation to other examining boards, can obtain them by application to the Medical Registrar. Students who have matriculated before 1880 will have to produce their certificates as heretofore.

N.B. Only those students who have attended three-fourths or upwards of the Courses of Lectures for which they have entered can present themselves for examination.

By order of the Medical School Committee,
HENRY W. MACINTOSH, Medical Registrar.
March 16th, 1883.

We trust that the example of Dublin University will be followed by every College or University throughout the Kingdom. Certificates have ceased to have any value, except, as the Reverend Dr. Haughton says, as receipts for money paid. They are not required by the English licensing bodies, and certainly the specific statement as to attendance which appears on the face of a schedule is far more reliable than any quantity of purchaseable certificates of "diligent" attendance.

Dalrymple Home for Inebriates.

At the meeting held on May 31st at the Mansion House, for the purpose of advocating the cause of the Dalrymple Home for Inebriates, there was a considerable attendance of influential friends of the movement, the Lord Mayor, Mr. Alderman Knight, presiding. In the course of his remarks, the chairman urged that at least £6,000 should be raised for the committee to be able to carry out the object in view; towards this one member had offered £500, provided nine similar amounts were forthcoming, either in single sums or in small amounts; and the Lord Mayor added that a friend of his own had promised to give £25, if nineteen others would come forward with a similar amount. In conclusion, he said that he felt convinced, after much experience as a magistrate, that there was such a person as an habitual drunkard, utterly unable to resist the temptation to drink, and he should be glad to see a Home founded and at work, to which such unfortunates could be taken. As a magistrate, he would like to have power, under an Act of Parliament, when habitual drunkards came before him, to send them to such a home, where they could be taken care of, and reformed from the dread habit of drunkenness, not only for the benefit of the drunkard himself, but also for society at large. During the meeting a letter was read by Dr. Norman Kerr, in which the writer, Mrs. Dalrymple, widow of the late Dr. Dalrymple, stated her willingness to increase her donation from £500 to £1,000, in the hope that the whole amount required might thereby be sooner subscribed. Dr. Farquharson, M.P., moved, and Dr. Alfred Carpenter seconded, a resolution to the effect that "The diseased state of many inebriates calls for their residence in some

institution where they can be placed under curative treatment, where the surroundings will be favourable to cure, and where there will be no temptation from the presence of intoxicating liquor." Several other resolutions were carried, and the meeting was altogether a very successful and encouraging one.

The Irish Prisons Board and its Medical Officers.

OUR readers may remember that some months since we recounted the history of an attempt by the Irish Prisons Board to dismiss one of the medical officers of the Dublin city prisons because he was indisposed to answer questions which the Board—contrary to law—was seeking to put to him. That officer, when threatened with dismissal, set the Board at defiance, and the Board, after much bluster and a remarkable display of ignorance of its own law, was obliged to cave in and leave the officer undisturbed. The experience thus acquired has not, it would appear, taught the Board to be wise, for it has recently attempted to superannuate another surgeon of the City of Dublin prisons as a punishment for his having refused to examine civil servants as to the condition of their health unless he be paid for doing so. That duty is a perfectly new one, thrust upon the prison surgeons in defiance of the 27th section of the Irish Prisons Act of 1878, and is a service entirely outside prison duties, performed for persons who are able to pay and who are not prison officers.

The second attempt of the General Prisons Board has resulted in greater misfortune than the first, for that Board has been obliged to withdraw its superannuating order, and leave the officer in possession of his office and full pay.

If permitted to offer a little advice to the Irish Prisons Board and the Local Government Board, we would recommend them to save themselves these public humiliations by employing some competent person to read their Acts of Parliament, and—when read—by striving to restrain themselves within the limits of those Acts.

A Too Successful Experiment.

IMMEDIATE explanation should be given of the facts surrounding the statement made in the House of Commons in reply to a question from Mr. Hopwood. The truth about the matter is that an official of the National Vaccine Establishment, Dr. Cory, of St. Thomas's Hospital, who entertains the view that inoculation from a true Hunterian chancre is not possible, has submitted himself to experiment with a view to testing the theory. After four times failing of success, he has at length, unfortunately, succeeded too well, a hard chancre on the arm being the result. Notwithstanding that the sore has been cut out, secondary and tertiary symptoms have followed in due course, and now we regret to say Dr. Cory is wholly incapacitated from regular work. Of course, capital will be made out of this event by anti-vaccinators, but with what small cause the history will prove.

THE Staines Urban Sanitary Authority have been fined £20, and ordered to pay 10s. costs, for causing or suffering offensive matter to flow into a watercourse communicating with the Thames.

Hospital Sunday in London.

THE annual collection at the various churches and chapels in the metropolis took place last Sunday, and in the Jewish synagogues the day previous, and, judging by the sums already sent in to the Mansion House, the prospect of a larger amount in the aggregate than heretofore is almost assured. Last year the total was between £35,000 and £36,000, which was considerably higher than that for any previous year. On the present occasion everything was in favour of the fund—the weather brilliant, without excessive heat, London full, and the State attendance of the Lord Mayor and suite both at St. Paul's Cathedral and Westminster Abbey. The only drawback is the discovery of an attempted fraud by persons at present unknown, who at the last moment sent a forged circular round to the various places of worship in the Lambeth district, intimating that collectors from the Mansion House would call for the amounts collected in order to save the trouble of remittance to head-quarters. Fortunately the police had timely warning, and it is hoped that no sums were paid over to these *so-disant* representatives of the Hospital Sunday Fund before the police had time to give the necessary warning.

The Tenure of Office of Irish Workhouse Surgeons.

THE Council of the Irish Medical Association has followed up its remonstrances against the attempt of the Irish Local Government Board to put the union officers under the foot of the guardians by a communication which it has sent to every workhouse medical officer in Ireland. This communication states the case, and gives the reiterated opinion of Mr. Purcell, Q.C., as to the illegality of the General Order promulgated by the Board, and proceeds as follows:—

“The Council of the Association has in vain solicited the Board to amend the objectionable articles of the recent General Order, or to submit the legality of their action for confirmation by the Law Officers of the Crown; but having been advised that the validity of the General Order can be tested at law only by an officer who has been dismissed or suspended by a board of guardians, the Council, therefore, is prevented taking the necessary steps to set aside the rules in question by application to the Court of Queen's Bench.

“From Mr. Purcell's opinion it follows that a dismissal or suspension by a board of guardians is wholly invalid; and that an officer is entitled (notwithstanding the General Order of the 18th of December, 1882, or any vote of the board of guardians founded thereon), to continue in his office, and to receive and recover at law, all his emoluments until he is formally removed by the Local Government under section 33 above quoted, the legal responsibility of such removal devolving solely upon that Board.

“The Council is prepared to consider the case of any officer dismissed or suspended by a board of guardians under this Order, with a view to proceedings to contest such dismissal at law where the circumstances appear to justify such action.”

We trust that an opportunity will arise before long to enable the Association to set aside this act of the Irish Local Government Board, for it would, in our opinion, be a disaster if the Board were permitted to shift its responsibility for dismissal to the guardians, or any one else.

It appears to us somewhat discreditable to the Board that we find it following the example of the Irish Prisons Board in attempting to override the Act of Parliament to the disadvantage of its own officers. If the Board is really in any doubt that its act is *ultra vires* and invalid it can readily obtain an opinion on the subject; but if it will not take that course, we think the Irish Medical Association should, as it proposes, do so on the very earliest occasion.

The Social Science Congress.

WE are informed that the subjects selected for discussion in the Health Section at the forthcoming annual meeting of the Social Science Congress, which is this year to be held at Huddersfield in October, are—

1. Is the modern system of education exerting any deleterious influence upon the health of the country?
2. Is it desirable to take any, and what further measures, to prevent the spread of zymotic diseases through the milk supply of our towns?
3. Is it desirable to amend or extend the Habitual Drunkards Act, and if so, in what direction?

Volunteer Medical Organisation.

THE executive committee of the Volunteer Medical Organisation held a meeting on June 1st, at Charing Cross Hospital, when the secretary reported on the considerable progress being made by the movement. Volunteer surgeons to the number of 51 have already placed their names on the general committee, and all the medical schools in London have now representatives in either the executive or general committee. The secretary was directed to convey to Messrs. Savory and Moore the thanks of the committee for the kind grant of 20 field haversacks complete, for the use of the Ambulance Company at Charing Cross Hospital. The National Aid Society have very courteously allowed the organisation to hold committee meetings at, and to have letters addressed to, their offices, 5 York Buildings, Adelphi. Besides Charing Cross Hospital, where a trained company already exists, St. Bartholomew's is about to take up the movement on a large scale. The London and St. George's are also moving in the matter.

The Council of the Royal College of Surgeons.

THE three members of the Council of the Royal College of Surgeons who retire this year by rotation are—Mr. John Cooper Forster, Vice-President of the College; Mr. John Birkett, President of the College in 1877; and Mr. Prescott G. Hewett, also a past President. Of these Mr. Cooper Forster only will seek re-election; and it is probable that most, if not all, of the following Fellows will be candidates for seats in the Council at the ensuing election:—Mr. George Lawson, of the Middlesex Hospital—Member, August 9, 1852; Fellow, December 17, 1857. Mr. Nottidge Charles Macnamara, of the Westminster Hospital—Member, April 17, 1854; Fellow, June 10, 1875. Mr. Oliver Pemberton, of the Birmingham General Hospital—Member, April 12, 1847; Fellow, April 18, 1875. Mr. Robert Brudenell Carter, of St. George's Hospital—Member, December 12, 1851; Fellow, 1864. Mr. Sydney Jones, of St. Thomas's Hospital—Member, April 4, 1853; Fellow, December 11, 1856. Sir William MacCormac, of

we have nothing but admiration ; although it must be added that the sections wherein the relations of the Council itself towards those guilty of fraudulent practices connected with unqualified practice, are dealt with, reflect the besetting weakness of the Council as a judicial body, and rightly enough have provoked a crushing and unanswerable retort from Dr. Ogle.

It was to be expected, as a matter of course, that objectors to the Council's proposals for preventing a continuance of unqualified practice would arise ; but we must confess to a feeling of real concern at the attitude assumed by our contemporary, the *British Medical Journal*, towards a reform that is as necessary as it is just. The whole weight of evidence is abundantly favourable to the main argument of Dr. Chambers' report, that, namely, the interests of the public and of the profession alike demand that every *responsible* medical practitioner shall be legally *qualified* to assume charge of the sick. So long as this primary truth is evaded, the whole matter in dispute is shelved ; and with it go also the principal factors that strengthen the hands of innovators pledged to remove existing abuses. It is no part of the duty of conscientious workers in the path of improvement to take into consideration what hardships will be suffered by men who are enjoying the fruits of unjustifiable practice when they are surrounded by disabilities of a penal nature, for the whole success of their lives has been obtained at the expense of risk to the public welfare. Indeed, so glaring are many of the abuses brought to light by recent inquiries—abuses inseparably associated with the employment of unqualified assistants—that excuses might be forthcoming for much more drastic proceedings than are proposed in Dr. Chambers' report ; and even in the utterances of apologists for the system which have appeared since the issue of the official document, it is not difficult to discover substantial reasons for speedy and effectual dealing with the problem in hand. The plea of expediency is naturally enough the principal one put forward in defence of giving to unqualified men the position that should never be occupied by them ; and the most frequently urged complaint against reformers is that they will, if they persist and succeed in their endeavours, be depriving the poor of a valuable and indispensable means of relief. This objection is plausible because it has a philanthropic ring ; but it is devoid of all foundation in fact. The services, cheaply purchased though they are, of the majority of unqualified assistants are in the end effective of little saving to the employer. It is true that he may, by a dereliction of duty, leave to his assistant the performance of tasks that can only be illegally fulfilled by such a representative, and he may thus conduce to his own more comfortable existence by prostituting his conscience and his honour ; but even the most diligent and successful unqualified assistant, sooner or later, plunges into error, in the consequences of which his principal is dragged no less than himself, and with results that not infrequently prove permanently injurious in a professional respect.

We are less concerned, however, to analyse the objections to reform at present, inasmuch as the voice of all those to whom the dignity and honour of their

calling are higher considerations than pecuniary advantage is unanimous in demanding such changes as will remove the reproach under which medicine suffers so long as its qualified followers lend their help in promoting the scandal of unqualified practice. Nothing could indicate more clearly the growth of opinion on this subject than the evidence of those who are quoted by Dr. Chambers as having replaced unqualified men by duly qualified assistants, with advantages they do not hesitate to acknowledge. It should be remembered, moreover, that sharp and sudden transition from the existing state of things to that under which unqualified assistants will no longer be permitted to exercise responsibility is deprecated by Dr. Chambers, and is not sought by even his most enthusiastic supporters. Sufficient time will be afforded for the accomplishment of necessary changes quietly and without undue interference with personal rights and privileges ; and under the new *régime* as much liberty as they now enjoy will still remain to medical men to be assisted, ministerially, by students who are, *bond fide, in statu pupillari*. Without entering into the merits of etymological quibbles, on which some partisans of unqualified assistants have striven to raise discussion, it may be at once admitted that the employment of assistants had its origin at a time when pupilage to a practitioner formed the sole means of medical education ; such a mode of obtaining help was both legitimate and useful, and aid so secured was confined within purely *ministerial* limits ; it did not, as it could not by any stretch of right, include performance of responsible functions, but only of duties which were discharged under the eye and direction of the *master*. It is a refinement of objection to urge that extension of this principle to that involving full responsibility on the part of *experienced* assistants is permissible and reasonable. It is *not*. For one thing, such an extension is illegal ; it ignores the privileges of qualification, and it at once places the man who has honourably pursued the curriculum and passed the examinations prescribed by law on a level of equality with the competitor who, either through incompetence or negligence, has failed to raise himself to the position of a qualified practitioner. Those, too, who employ such unqualified men are guilty of the offence which the latter themselves commit against registered practitioners ; and the mere question of moral right has, when properly appreciated, so strongly appealed to the senses of some employers of unqualified men that it has influenced them to cease pursuing an objectionable practice.

It would be premature to speculate just now on the probabilities of the suggestions made in the report being carried to fulfilment ; and it may probably be for the best if any immediate legislation is not the result of it. It is infinitely to be preferred that amendment should come from within the profession, of its own volition, and as the practical outcome of a general feeling condemnatory of the evils attendant on a most vicious system. Such improvement may possibly be of slow growth, but it is not difficult to perceive the germs of it already expanding ; and as it increases it will naturally react on larger and larger circles to the extinction of the reproach.

In the limits of an article like this we have been unable to discuss in detail the numerous points raised in Dr. Chambers' report; but this is the less necessary, since, as stated above, the report is mainly in agreement with our own utterances; and we may be content with directing attention to, and advocating, the suggestions for change and improvement contained in the report, while fully agreeing also with the most stringent recommendations formulated in the document.

THE IRISH LUNATIC POOR BILL.

LORD CARLINGFORD has, within the past week, presented to the Lords a most important Bill, to provide for the maintenance of harmless lunatics in Ireland, and also to reconstruct the Irish Lunacy Department. The first part of the measure is practically identical with the Bill which was introduced by Mr. Litton, Q.C., in 1880, and which was of necessity dropped by him when he accepted the Commissionership of the Land Court. The same measure was, in the next session, taken in hand by Lord O'Hagan, and for the second time it was abandoned when his Lordship resigned the Chancellorship. For the third time the Bill appears now as a Government measure, and we trust that this time it will pass, if, indeed, the block of business in the Lower House will permit of its being got through its stages there.

There is, strange to say, no method at present provided for the certifying of harmless pauper lunatics in Ireland. The dispensary medical officer may be served with a ticket to visit such a patient, and must attend and prescribe, but it is not a part of his duty to certify anything unless he is retained and paid as a private practitioner by the patient's relatives, and even then the process of getting such patient into an asylum is so complex that any easier method of disposal is preferred. That method is found in the Dangerous Lunatics Act, which enables a magistrate to commit to an asylum a lunatic who is apprehended by the police as dangerous, and under this Act it is customary to regard all sorts of lunatics as dangerous, and to treat them accordingly.

Lord Carlingford's Bill is simply an extension of certain parts of the English lunacy law to Ireland. Under its provisions a constable or relieving officer "who has knowledge that . . . any person is deemed to be a lunatic, and that such person is . . . not under proper care or control, or is cruelly treated or neglected . . . shall give information to a magistrate," who may, thereupon, either visit the patient or direct the nearest dispensary medical officer to do so, and to report in writing, and if he be satisfied of the truth of the information, the magistrate may cause the lunatic to be brought before two magistrates, who, on further examination and a further medical report, may, if they are satisfied that "his lunacy is chronic, and that he is harmless," remit him to the nearest workhouse, or may place him in the custody of some relative who will take care of him.

For examination and certifying of lunatics each medical officer is to receive a fee such as the justices order, not exceeding £1, or, for both the preliminary and subsequent proceedings, £1 10s., to be paid by the guardians, and any relative of the lunatic who would be chargeable for his relief in workhouse is to pay for his maintenance.

Those lunatics who are boarded out of the workhouse, or with relatives, are to be visited and reported on twice a year by the local dispensary doctor, who is to receive 5s. for each such visit.

The third part of the Bill provides for the reorganisation of the Central Lunacy Department. The office now existing in Dublin Castle is to be merged in the Local Government Board for Ireland, and the two inspectors, Drs. Nugent and Hatchell, to cease to hold office. Two new inspectors are to be appointed under the Board, "being physicians or surgeons of seven years' standing, to assist in carrying out" the new system, but either of the existing inspectors of lunacy may be drafted into charge of the department under the Local Government Board.

It will be seen that this is a measure of the highest importance, and requiring more consideration of detail than we can give to it at the present moment. On a first inspection, and after full consideration of the former Bills on which it is based, and of the fact that the system has had ample trial in England, and been found to work well, we feel able to give its proposal our unqualified approval. Its provisions for the custody of harmless lunatics are much needed, and they will enable a large part of the lunatic population to be provided for in workhouses at a cost which will be only a fraction of their expense of maintenance in district asylums. The departmental part of the Bill is also much needed, and we think it a wise proposal that the pauper lunacy administration of Ireland shall be placed under the same control as the other arrangements for the relief of the poor.

We trust that in the selection of inspectors by the Board the principle of promotion from the ranks of the department will not be forgotten, and that we shall not see outsiders with political influence placed over the heads of competent and experienced Poor-law officers.

SCOTCH INTERESTS AND THE NEW MEDICAL BILL.

At the important meeting referred to in another column, representatives of the University of Glasgow were present in the persons of Drs. Leishman and Young, and the former of these gentlemen, in a speech conspicuous for moderation and gentlemanly good taste, said the best that could be said, and in the best possible manner, for the Universities of Scotland, a fact on which, considering recent exhibitions, the University of Glasgow is to be congratulated. So great is our respect for Dr. Leishman's excellent address, and so conscious are we of the deserved weight which it will carry, that we cannot allow it to pass without indicating its salient features and the manner in which his arguments have been answered by Dr. MacVail. Dr. Leishman does not deny that at present the Universities possess a monopoly, but he contends, in opposition to the document issued by this meeting, which he describes as "fantastic in its extravagance," that no new monopoly was created by the Bill, nor could he see that there was freedom in any sense at present enjoyed by the extra-mural teachers of which it was in contemplation to deprive them. Now it will be admitted by most people as an ultimate fact that the nature of the monopoly at present enjoyed by the Universities is the extent to which

teachers are examiners. So long as teachers continue to be examiners, and to the extent that they are so, to that degree is there an unfair advantage accorded to them in competitive teaching, as students will naturally gravitate, no matter what the relative differences of merit as teachers, towards those who are to examine them for their qualifications. Certain obvious results flow from this. In the first place, medical reform, to make any pretensions to completeness, must recognise the fact that the teaching and the qualifying functions be completely severed. Medical reform will, therefore, be incomplete to the extent that they are *not* severed. Now at present in Scotland it is possible for a student to receive a complete course of medical education, and a legal qualification or qualifications from one of the Corporations, without going near a University, whereas, as it at present stands, the new Bill provides that the new Medical Board for Scotland will consist of *eight* University and *only three* Corporation members. It is thus undeniable, in opposition to the view of Dr. Leishman, that if no new monopoly is created the present one is mischievously strengthened at the expense of the Scotch Corporations. That this provision, if it become law, will be unfair to the extra-mural teachers, and prejudicially affect the extra-mural schools, does not require to be insisted upon.

Dr. Leishman further contended that the disparity of the present numbers on the Divisional Board, if carefully looked into, disappears, seeing that the University of St. Andrews, being more of an examining than a teaching body, its vote would be invariably given in favour of the Corporations, and the numbers would thus become, not eight to three, but seven to four. There is a tacit acknowledgment in this contention that all voting in the Divisional Board will be determined by interest, and on this point all that requires to be said is that any board influenced by any interest whatever in passing men into the profession is unwholesome, and can never command public or professional confidence. If the Universities must necessarily give seven votes in favour of their pecuniary interests, and the Corporations, in like manner, give four, the University preponderance would surely continue strong enough.

In answer to the charge that the Scotch Universities were consulted as to the relative numbers on the Divisional Board, Dr. Leishman frankly says: "No one connected with the Scotch Universities knew, until the Bill was issued, what the numbers of these Divisional Boards were to be, and he confessed frankly, for his own part, that when he read the numbers he was rather astonished, because he did not think that, whatever the sins of the Corporations of Scotland might have been, they were *not* sins of that deep dye which called for such reproof as was embodied in these numbers." It was not in the disparity of numbers in the Divisional Board that Dr. Leishman considered that danger lay to the extra-mural schools; it lay in the deep-seated feeling which existed in England against the Scotch schools, as England had been jealous for many years of the surprising success of the Scottish schools, and he pointed out that whatever a medical board did was subject to a Medical Council—a board sitting in London, the majority of its members being always Englishmen. Scotland and Ireland would be in a minority,

and appeal from that board was to the Privy Council, and "they all knew what the Medical Department of the Privy Council was." Dr. Leishman is thus perfectly willing to take a gift of eight University representatives from these gentlemen, of whose sense of fairness in the matter of appeal he has such serious misgiving.

As a former lecturer of the Glasgow Extra-Mural School, Dr. Leishman fell into a singular error as to the long-continued hostility of the University towards "the Andersonian." He stated that the University was advised by the Lord President of the Court of Session that so long as the Andersonian University, which was the only extra-mural school then existing, called itself a University, without having a charter, it could not be recognised. Dr. McVail cogently points out, in reply to this, that the University of Edinburgh was under the same legal enactments as that of Glasgow, and that it did not refuse recognition of the lecturers of this school, and that, in point of fact, the change on the part of the University towards its rival had no relationship whatever to the change of name or constitution, as it took place *prior* to that event by about two years. Dr. Leishman's advocacy of the University being, therefore, as we believe, about the best possible, it simply serves to show the inherent weakness of the case he defended with such success as a pleader.

Notes on Current Topics.

Chloroform Narcosis During Sleep.

A CORRESPONDENT of our New York contemporary, the *Medical Record*, having recently given expression to doubts concerning the possibility of inducing chloroform narcosis in sleeping persons, communications affirming the opposite have been contributed to the same journal by other observers. These are of considerable interest on account of their being illustrated by records of actual experiments purposely made with a view to solving the problem, Dr. Davis Haldermann adducing two successful instances in which he himself was the operator, and Dr. E. M. Nelson one. These examples added to those previously recorded sufficiently establish the truth of the statement which has been called in question; and the subject possesses also an interest which entitles it to consideration. Not very long ago it arose in this country in connection with the performances of burglars, certain of the more daring of whom were popularly charged with invoking chloroform to their assistance while carrying out their designs. On the evidence proffered by the physicians named above, however, it is shown that to be successfully applied the narcotic must be very gradually and cautiously brought within breathing distance of the subject of the experiment, the cloth or other instrument must be held at first as far as two feet away from the sleeper's face, so sparingly to dilute the atmosphere for some distance around, with the primary object of blunting the air passages, and thus avoid the liability of reflex disturbances, the abrupt excitation of which leads to failure in those trials which fail of success. The practical application of this method of narcosis is well shown by one of the cases quoted, that of a boy on whom the operation of circumcision was performed during insensibility produced while

the patient was asleep in bed. Children offer peculiarly favourable subjects in this respect, and by pursuing such a course with them much terror and apprehension caused by preparations made in their waking presence might be happily avoided.

Voters in Irish County Infirmaries.

QUESTIONS have arisen, in connection with the recent election of a surgeon to the County Roscommon Infirmary, as to the period at which the subscription of a governor ought to be paid to entitle him to vote in the election. On looking into the law of the matter, we find that by the 3rd section of 47 George III., cap. 50, passed in 1807, "Every donor of any sum not less than twenty guineas . . . shall, from the time of such donation, be one of the governors or governesses, and a member of the body corporate of such respective infirmary . . . for one year from the day of the payment of such subscription." By the 4th section of a subsequent Act—54 George III., cap. 62—it is provided, "That no annual governor or governors of any such infirmary shall be permitted to vote at the election of such infirmary upon any vacancy in such office (the surgeoncy) unless he shall have paid the subscription by virtue of which he claims a right to vote at such election two years at the least before any such vacancy shall have occurred." By the 9th section of 3rd and 4th William IV., cap. 92 (1883), this latter limitation is altered to one year. It thus appears that no one is entitled to vote in respect of any subscription paid subsequently to a year before the death or resignation of the surgeon. This is a strange limitation, and, it seems, might be read so as to exclude the votes of all annual subscribers, because, as the election must necessarily take place after the death or resignation, none of them could possibly vote until after the twelve months preceding the vacancy had lapsed; and if they voted at all, they must do so in respect of the previous year, and not the current year's subscription.

The Parkes Museum.

THE Council of the Parkes Museum of Hygiene, which is now definitely located in its new home at 74A Margaret Street, Regent Street, W., has just issued a circular letter setting forth the objects to forward which the institution has been founded, and inviting the hearty co-operation of all who are interested in the progress of sanitary science. The most effectual support that can be afforded, and such as can be rendered by all who have the will to proffer it, may be given in the assurance that good will result; and by enrolling themselves as members of the Museum, profession and public may alike contribute to the success that is so well merited. The annual subscription for members is one guinea; or a life composition of ten guineas confers the privileges of membership, including free use of the museum, library, and reading room, and admission to lectures and demonstrations. Several of the latter have already been given, in the presence of considerable and appreciative audiences, and a programme of other similar meetings is arranged for the current session. It is to be hoped that an ungrudging support will be accorded to the Museum, and all who desire to obtain further information concerning it may do so on application to the Hon. Secretary, Dr. Dawson Williams, at the institution.

Nitrous Oxide for Prolonged Anæsthesia.

THE only method of administering nitrous oxide for prolonged anæsthesia, so far successfully used, has been to use it mixed with air or oxygen at considerably more than ordinary atmospheric pressure, which required the immersing of the patient, operator, assistant, &c., in an isolated condensed air chamber. On the 30th of April last, however, M. Bert described, before the French Academy of Science, experiments upon animals, with a view of accomplishing the same end by the *alternate* exhibition of the nitrogen protoxide and oxygen gas at the ordinary pressure. It was only necessary to connect with the ordinary mask or inhaling facepiece another tube from a bag of oxygen. When insensibility is produced by the laughing-gas, oxygen is for the moment given to avert asphyxia. This reoxydises the blood sufficiently to allow the nitrous oxide to be continued, without restoring sensibility. By these means, animals—such as dogs—were kept alive and insensible for half-an-hour or more without bad after-results.

Research Rewards in France.

THE treatment of M. Pasteur by his countrymen offers a striking example of the gratitude of a nation for benefits conferred on it as a result of scientific research, and might not inappropriately find imitation in other countries than France. A committee having been appointed by the French Parliament to consider the question of the pension awarded to M. Pasteur by the Government, and which has hitherto been £450, has recommended that the amount be increased to £1,000 per annum, and that it should revert to the widow and children of the *savant* after his death. As a mere return for the services it acknowledges no money payment could, of course, be sufficient; but as an evidence of grateful appreciation the action thus taken by the committee is eminently encouraging to research.

Sanitary Insurance in Dublin.

A SPECIAL general meeting of the Dublin Sanitary Association was held on Monday week, for the purpose of amending the rules of the Association so as to enable it to place the benefits of "sanitary protection" within the reach of its members. On the motion of Dr. Grimshaw, the Registrar-General for Ireland, it was resolved, "That the following (fifth) object be added to the four for which the Association was originally founded, viz.:—To provide its members, at moderate cost, with such advice and supervision as shall insure a proper sanitary condition of their own dwellings, and enable them to procure practical advice as to the best means of remedying the defects in the houses of the poorer classes in which they are interested."

This is an admirable addition to the usefulness of the Association, and we have no doubt the sanitary insurance which is offered will be largely availed of by the Dublin public. We hope, however, that the executive of the Association will instruct its sanitary inspectors to keep their suggestions within practical bounds, for we know as a fact that house proprietors are usually deterred from calling in a sanitary adviser by apprehension that they will be called upon to undertake large, troublesome, and expensive works.

No doubt it is good policy to make the sanitation of a house quite perfect when it needs reconstruction, but such a proceeding is seldom within the means of a house-owner, and never within his inclination, while he may be perfectly willing and able to effect useful changes. When the sanitary insurance system develops in Dublin—as we hope it will—it would be a great matter if the Association could arrive at a price list, or approximate estimate of cost of works, for there is no class of tradesmen so much feared by the public as sewer-doctors, and none whose work is, generally, worse or more exorbitant in cost.

Professorships at Cambridge.

APPOINTMENTS have recently been made at Cambridge to the new Chair of Physiology founded as a result of the Royal Commission, and to that of Anatomy vacated by the resignation of Dr. Humphry, who has generously taken over the duties of Professor of Surgery without stipend. To fill the Physiology Chair, Dr. Michael Foster has been chosen, and no more fitting occupant could possibly have been selected. Dr. Foster, moreover, has so identified himself with the teaching of this branch of science in the University that any other selection would have appeared almost unnatural. His services have amply merited this recognition of them; to have lost them from any cause would have been an irreparable blow to the great school whose fortunes he has so materially advanced. The second professorship, that of Anatomy, has been offered to and accepted by Dr. Alexander Macalister, Professor of Comparative Anatomy and Zoology in Dublin University.

The Practical Result of the Anti-Contagious Act Agitation.

DR. A. CONAN DOYLE, of Portsmouth, writes to the daily papers to the following effect:—

“As an ounce of fact is proverbially superior to an indefinite quantity of theory, I think that I am justified in citing one or two instances of the effects of the present suspension of the Acts. Being in practice as a medical man in the town most affected by the measure, I am able to speak with some authority on the subject. Last week a large transport entered Portsmouth Harbour with time-expired men from India. Upon the same day several diseased women left the hospital presumably with the intention of meeting that transport, and there was no law to prevent it. I say that if an unfortunate soldier, coming home to his native land after an absence of years, and exposed to such temptations, should yield to them, and entail disease upon himself and his offspring, the chief fault should not lie at his door. It surely emanates logically from those hysterical legislators who set loose these bearers of contagion, and their like, upon society. For fear delicacy should be offended where no touch of delicacy exists, dreadful evils are to result, men to suffer, children to die, and pure women to inherit unspeakable evils.”

It is truly a subject for just indignation that the moral hallucinations of a few misguided philanthropic theorists should have induced the Government to deprive the public of the protection which these Acts afforded, and this in the face of the repeated judicial decisions of Committees of Parliament that these Acts were necessary to the public weal, and a hardship on no decent member of society. The subject is one in which our profession may reasonably be looked to to take a strong position, and the

present circumstances are such as to call for vigorous action. Agitation can only be met by counter-agitation, and as the promoters of syphilis infection have succeeded in creating a false idea in a section of the public, and in squeezing the Government, it becomes urgently necessary for the profession to educate the public as to the utter falsity of the statements made by these anti-Act fanatics. We therefore urge our brethren to throw themselves with enthusiasm into the effort to restore to the public the benefits of protection against syphilitic disease. The Society for promoting the extension of the Acts is ready for work, but it needs increased moral support, and the sinews of war, and our profession is bound to give that aid. A brisk campaign between this and next session of Parliament would, we fully believe, lead to the restoration of the grant for carrying the Acts into effect which has been withdrawn by the Government.

Physiology at Oxford.

THE advent of Dr. Burdon Sanderson to Oxford in the capacity of Waynflete Professor of Physiology has naturally led to vigorous exertions on his part for speedily providing the University with increased laboratory accommodation in keeping with the advances made by modern scientific methods and research. At a late meeting of Convocation, therefore, a proposal to apply the sum of £10,000 from the University chest, for the purpose of supplying the new professor with working room, was brought under discussion, and raised, as might be expected, much opposition among the clerical party, who chiefly objected to facilitating vivisection, this being, in their estimation, the logical outcome of physiological instruction. Fortunately for the credit of Oxford as much as for the advantage of study, the attempt to withhold the vote was a failure, and it was eventually carried by a narrow majority of 3, 88 voting for, and 85 against, the motion. There is now a fair prospect that Oxford will become a worthy rival of Cambridge in the work done by its members in behalf of experimental science.

“Infamous Conduct in a Professional Respect.”

AMONGST the light thrown upon the trade in fictitious lecture and hospital certificates, by the recent discussion in the Dublin College of Surgeons, a remarkable statement made by Mr. Macnamara, representative of the College on the General Medical Council, deserves special notice. Mr. Macnamara, speaking officially and authoritatively on behalf of the Medical Council, stated that, while that Council did not wish to place a restriction on the hour at which lectures might be delivered, it was unanimately determined to treat the issue of a fictitious certificate—if proved against any teacher—as (to use the words of the Act of Parliament) “infamous conduct in a professional respect,” and to punish it rigorously by erasure of the offender's name from the Register.

This is truly a new departure, considering that the five Irish members of the General Medical Council must for years past have been thoroughly conscious that this “infamous conduct” was of every-day notoriety, and considering that the evidences of its prevalence were to be found in the Council's own minutes.

In order to be prepared with evidence on the point, we should like to know what the Irish Branch Council would consider sufficient proof of the falsity of a certificate? Would it suffice them to have evidence of a sheaf of certificates of diligence signed by a teacher who never delivered a single lecture of those certified, and never saw the face of one of the students of whose diligence he testified?—would it convince them if proof were presented of a gentleman who within a comparatively recent period obtained the highest qualification of an Irish licensing body by virtue of a certificate which he bought for £3 3s. from a school where his name was never even entered for the course, such certificate being ante-dated 15 years by the vendors to suit the period of his studentship? or would they prefer evidence of the "diligent" attendance on a Dublin *annus medicus* by a student resident for that period in Australia?

The pretence of unconsciousness comes too late, for we can answer for it that—if the five members of the Irish Branch Council and its Registrar were in innocence of the wholesale trade in fictitious certificates in Dublin—they are the only six gentlemen in the Irish medico-educational community so ill-informed.

Mercuric Chloride as a Germicide.

A VERY interesting summary recently appeared in the *Practitioner* of a paper by Professor Koch, giving the results of some investigations into the comparative value of disinfectants, or germicides. He found that, as regards the action on bacteria, bacilli and micrococci, by far the most potent disinfectant was corrosive sublimate; a solution of 1 per 1,000 of mercuric chloride killed the strongest of these at once, whilst even solutions of 1 in 10,000 and 1 in 15,000 were sufficient to destroy many micro-organisms. He remarks that the poisonous action of such dilute solutions may be entirely disregarded. A five per cent. solution of carbolic acid, used under the same conditions, was ineffectual. Salicylic acid and thymol were about equal in value to carbolic acid. Other mercurial salts, as the sulphate and nitrate, were found to be quite as efficient as the chloride. A French chemist, M. de la Croix, who has been making experiments of a somewhat similar nature, arrives at nearly the same conclusions.

A Medical Reserve Force.

THE French Minister of War has just declared that he considers it quite indispensable for doctors and apothecaries to practise in time of peace the duties which are necessary in war, and he has requested the Minister for the Interior to inform him under what conditions these functionaries can be called together for this purpose. At present they are only obliged to appear once a year, at a fixed date, before the Controller of the Medical Department. The *Temps*, which gives this information, thinks that it would be advisable to call out at the same time both the doctors of the reserve and those of the active force, as by this means the former would be aided by the latter in the explaining of the various duties, and would also become acquainted with the details of military life. The reserve numbers about 900 doctors and 100 dispensers.

Scotch Licences.

THE Scottish correspondent of the *Lancet* says, last week:—As an evidence of how the wind blows, it may be mentioned that in the last published list of those receiving the licence of the College of Physicians, Edinburgh, only one had residence in Scotland. Of the eleven, eight were from London, one from Bristol, one from Canada, and one from Glasgow.

The Prospects of the Medical Bill.

THOSE whose "wish is father to the thought" have been gratifying themselves by circulating a rumour that the Medical Bill will not be proceeded with this session, for which statement we believe there is no better foundation than the backward state of the session. We have authority for saying that the Vice-President of the Privy Council, who has charge of the Bill, never had the least idea of dropping it, and that it will be placed on the notice paper *au sérieux* on the first opportunity which can be got.

The Briton Medical Life Assurance.

THIS Association, which has always been largely patronised by the profession, has just issued its annual report, which is of a decidedly favourable character. No less a sum than £21,573 was received from premiums during the year, and £4,708 constituted the new business. We hope the new business is chiefly from insurance of medical men, as it would thus afford practical evidence that they were becoming more alive to the necessity of life assurance in providing for the proverbial rainy day.

Stronger testimony in favour of total abstinence could scarcely be desired by its most ardent advocate than is found in the report before us, where the directors state that after mature deliberation they have decided to offer the advantages of lower rates "to total abstainers from alcoholic beverages." From a pecuniary point of view the Briton Life Association is in a decidedly favourable position, as the directors are able to recommend that a dividend of 5 per cent. on the balance of the capital be declared, free of income tax, out of which an interim dividend, for the first six months, has already been paid.

The Poor-law Superannuation Bill.

A PARAGRAPH appeared last week in the *Freeman's Journal* to the effect that at the meeting of the Irish Parliamentary party a lengthened discussion took place on the report of the sub-committee appointed to examine the Poor-law Officers' Superannuation Bill. The general feeling of the meeting was against allowing the Local Government Board the power of interfering with the superannuation allowances granted by the guardians. A conversation also took place as to the desirability of introducing an amendment giving the boards of guardians discretionary power in fixing the amount of the allowance and relieving them from the compulsion proposed to be placed upon them by the Bill of adhering to the scale contained in it.

We are glad to be able to state our belief that the views here expressed are not those either of the leaders of the Irish party or a majority. Discretionary superannuation could not be for a moment thought of by those who

are promoting the Bill, and, moreover, it will not be tolerated by the Government, inasmuch as the Bill would be entirely valueless as a settlement of the difficulty if guardians were empowered to do as they pleased with their officers' pensions. We believe that Mr. Herbert Gladstone will make any reasonable or possible concession to meet the opposition of Mr. Biggar and his party, but—if it be not found possible to do so—the Bill will be pressed to an issue this session in spite of their blocks.

Telephonic Night Service for Dublin.

THE Telephone Company has announced that on and after Monday last the exchange will be kept open night and day. Thus the chief difficulty in the way of the employment of this method of medical inter-communication is removed, and we hope to see, as a consequence, the extension of the wires to all the hospitals, and most of the practitioners of Dublin.

Factory Inspectors.

A CIRCULAR has been issued by Mr. Redgrave, the Chief of the Factory Inspection Department, asking certifying surgeons to make a return of the number of firms with whom contracts are made by them for periodical visits, and how much they are worth, and also the value of the fines received. This is a movement by the authorities which, however inconvenient to individuals, must be approved in the public interest. The truth is that the Act of Parliament intended that the certifying surgeon should be altogether independent of the factory owner, and it set down a tariff of fees payable for periodical inspection. But, after a time, it came to be tolerated by the central department (and therefore usual with certifying surgeons) to contract themselves out of the provisions of the Act and make private arrangements with the factory owners such as would be mutually comfortable. The effect of this laxity was to make the surgeon, more or less, the *employé* of the owner, and to make him unwilling to vex the owner by any excess of official enthusiasm, *et hinc illæ lacrymæ*, abuses have crept in and the central department is called upon to move in the matter.

The Pathogenesis of Uræmic Eclampsia.

DR. SNYERS, of Liege, has recently submitted the various theories as to the origin of so-called uræmic accidents to an experimental examination, carried out in Stricker's laboratory in Vienna, with the result that each was shown to be untenable. The various theories examined and rejected in turn were—(1) that of Wilson, who held that the uræmic symptoms depend on retention and accumulation of urea in the blood; (2) that of Frerichs, that they are caused by the change of urea into carbonate of ammonia. The author concluded that the quantity of carbonate of ammonia in the blood of uræmic dogs was far too small to cause death. (3) That of Schottin, to the effect that the effete material accumulates in the blood before it becomes changed into urea. This also was rejected. (4) That of Traube who held that the symptoms are produced by œdema and consecutive anæmia of the brain. The author found that if increased blood pressure was avoided, œdema of the brain failed to produce the

symptoms. (5) That of Feltz and Ritter, who believed that the potash salts of the urine were the agents of uræmic intoxication. The author concluded that the amount of potash salts in the blood was too small for the symptoms to be fairly attributed to them. He also examined the blood in two cases of puerperal eclampsia and failed to discover any increase in the amount of the potash salts. The author remarks in conclusion that none of the present theories suffice to explain the whole train of symptoms of uræmia. This is quite true of the theories passed under review by the author, but another theory recently set on foot, in which the above train of symptoms is attributed to nervous causes, the so-called uræmia playing but an accidental and secondary part, or even no part at all, would seem to be supported in a negative manner at least by our author's observations.

Ready Method of Intravenous Injection.

It appears certain that the intravenous injection of saline fluids in cases of acute general anæmia has a great future before it. One obstacle to the more extended employment of this eminently conservative operation has been the absence of suitable and inexpensive apparatus. It is true that we have had quite recently brought before our notice apparatus well adapted for the purpose, and of moderate price. It is still uncertain, however, whether any great number of practitioners will care to spend even so small a sum as a couple of guineas on the purchase of an instrument they may never have an opportunity of using. Under these circumstances it will, perhaps, be interesting to learn how intravenous injection has been performed in a case of emergency, in which no specially designed apparatus was at hand. Such a case occurred in the practice of Dr. L. Szuman, of Thorn, and is reported in the last number of the *Berliner Klinische Wochenschrift*:—The patient was a youth, 15 years of age, who had met with an accident, resulting in serious hæmorrhage, likely to prove fatal. An apparatus for intravenous injection was extemporised on the spot, and the injection made, with a happy result. A piece of fine drainage tubing, not perforated, was attached to the nozzle of an irrigator (a flat old-fashioned infant's feeding bottle would answer the purpose very well.) The solution employed was—water 1000 grm., table salt 6 grm., and bicarbonate of soda 1 grm. The left median vein was exposed, separated by passing under it two hollow sounde, a trocar 1½ mm. in diameter was then introduced until the point of the stilette was well in the vein, when the stilette was withdrawn a little. The canula was then pushed in to a depth of about 1½ ctm. A ligature was then applied round the vein over the canula, the stilette withdrawn, and the tubing drawn over the free end of the canula. The irrigator was then raised about 1 metre in height. When the solution flowed into the vein. 760 grms. were employed. After the injection was completed the vein was ligatured on the peripheral side of the puncture. The operator is to be congratulated on his ability to make use of such apparatus as was at his command, and by means of it tide his patient over a danger that would most likely have proved fatal but for his readiness in thus adapting simple means to an unusual purpose. Let us hope that the lesson thus taught may not be taught in vain.

WE are informed that H.R.H. the Duchess of Albany has fixed Tuesday, July the 4th, for the opening ceremony of the new Chelsea Hospital for Women.

DR. GRAINGER STEWART was presented at Her Majesty's levée, on Friday last, by the Lord Chamberlain, on his appointment as Physician in Ordinary to the Queen for Scotland.

THE degree of Master of Laws of the University of Cambridge has been conferred on Dr. William Collingridge, M.A., M.D., S. Sc. Cert. Camb., Medical Officer of Health of the Port of London.

THE Rolleston Memorial Fund, amounting to £1,200, has been handed over to the University of Oxford for the foundation of a prize for original research in animal and vegetable morphology and physiology, to be awarded every two years.

At the last meeting of the Paris Academy of Medicine, M. Regnaud stated that bichloride of methylene, the anæsthetic which is so much used in England, is composed simply of a mixture of 4 parts chloroform and 1 part spirit of wood. By adding this spirit of wood to the chloroform the cost of manufacture is increased to 47l. 75c., instead of 10l., which is the price in France. It ought, however, to be made cheaper, as the spirit of wood is, he contends, of little value.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Bristol 14; Portsmouth 15; Cardiff, 16; Edinburgh, Oldham, Leeds, Nottingham, Bradford, Brighton, Huddersfield 17; Birkenhead, Hull, Birmingham, Salford, London, Leicester 18; Norwich, Plymouth 19; Halifax, Bolton, Wolverhampton 20; Manchester, Preston, Sunderland 22; Derby 23; Newcastle-on-Tyne 24; Liverpool, Sheffield 25; Dublin, Blackburn 28; Glasgow 33.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 38, Bombay 28, Madras 34, Geneva 23, Brussels 26, Amsterdam 27, Rotterdam 28, The Hague 28, Copenhagen 22, Stockholm 24, Christiania 13, St. Petersburg 36, Berlin 28, Hamburg 33, Dresden 26, Breslau 28, Munich 32, Vienna 32, Prague 42, Buda-Pesth 32, Trieste 25, Rome 30, Turin 22, Venice 22, Lisbon 27, New York 24, Brooklyn 22, Philadelphia 19, Baltimore 18.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

CURIOUS CASE OF POISONING.—A case of unusual interest is at present engaging the attention of the Glasgow authorities. Last week a young man, named George Mackay, residing in Crawford Street, Partick, was suffering from a severe cold, and the practitioner who was consulted prescribed a usual remedy. On partaking of the medicine the young man became alarmingly ill, and he died suddenly, in the belief

that he had been poisoned. In order to test the matter the doctor himself partook of some of the medicine, and, being seized with decided symptoms of poisoning, he was obliged to resort to antidotes to free himself from danger. Accordingly, in making out a certificate of death, he assigned as the cause "suspected poisoning." The matter was thus brought under the notice of the authorities, and a post-mortem examination having been made, the belief that the young man had been poisoned was confirmed. The prescription on examination was found to be quite correct, and it had been accurately copied in the books of the chemist who dispensed the medicine.

EDINBURGH.—HEALTH OF THE CITY.—The mortality of Edinburgh for the week ending with Saturday, the 9th inst., was 74, and the death-rate 17 per 1,000 per annum. There were 8 deaths above 1 year and 26 above 60, of which 6 were above 80 years. Diseases of the chest accounted for 26 deaths, and zymotic causes for 6, of which 1 was due to fever, 1 to scarlatina, and 2 to measles. The intimations of these diseases for the week numbered 7, 12, and 44 respectively.

GLASGOW DEATH-RATE.—For the week ending with Saturday, the 9th inst., the mortality in Glasgow was at the rate of 34 per 1,000 per annum, against 27 in the preceding week, and 24 in the corresponding week last year.

DUNDEE ROYAL INFIRMARY.—The annual meeting of the Governors of the Royal Infirmary, Dundee, was held on the 11th inst., Ex-Provost Rough in the chair. The report for the year stated that 1,931 patients had been admitted, being 279 more than in 1882. There had been 174 fever cases, the number being higher than in any year since 1875, the increase being due to typhoid. The total medical and surgical cases together was 1,744, being 206 more than in 1882, and higher than in any year since 1866. The daily average number of patients throughout the year in the house was 140. The number of deaths had been 167, or equal to 8·7 per cent., the rate in 1882 being 7 per cent. The medical mortality was 10 per cent.; surgical, 5·5 per cent.; fever, 12 per cent.; and 1,027 patients had been attended at the waiting-room, and 7,883 out of the house. During the year £1,974 had been received in donations and legacies for investment; £2,094 in legacies, and £4,910 for the children's ward. At the convalescent home 490 patients had been admitted, being 167 more than in 1882. The income for the year was £6,819 17s. 1d., and the expenditure £5,997 17s. 4d., leaving a surplus of £821 19s. 9d. The extraordinary expenditure for renewal of the infirmary buildings was £1,736 16s. 5d., and the extraordinary revenue £156 3s. 7d. The total deficiency at the end of the year was £758 18s. 1d. The reports were unanimously approved of, and directors and other officials were appointed for the year. A vote of thanks to the chairman terminated the proceedings.

MONTROSE ASYLUM AND INFIRMARY BOARD.—The annual meeting of the directors of these institutions was held on the 12th inst., Provost Leckie in the chair. The Asylum accounts showed a profit on the year of £545 7s. 11d. The number of patients in the Asylum on 14th May was 510, as compared with 488 at the same date last year. Up to the end of the year over £1,000 had been spent on additional works, and 80 beds had been added to the accommodation of the house. From the Infirmary it was reported that during the year 161 patients had been admitted. The total revenue, exclusive of legacies, had been £837 10s. 8d., and legacies to the amount of £430 had been received. In the Asylum the recoveries had been in the ratio of 30·7 to the admissions, and the deaths 8·17 to the average number resident during the year. The

officials were all re-elected. Dr. Lawrence was unanimously appointed first medical officer for the Infirmary, and Dr. Kay assistant medical officer.

NEW DISTRICT LUNATIC ASYLUM.—At a meeting of the Lunacy Board of the county of Lanark, held in the Council Chambers, Glasgow, on the 13th inst., the Committee concluded the final arrangements with Mr. Peter Forrest, of Shotts, for the acquisition of his lands of Hartwood and Bow-housebog, of about 500 acres. At the same time, arrangements were made for purchasing two small adjoining properties, which will bring up the total area to about 600 acres, at a total cost of £26,500. The distance from Glasgow is about fifteen miles by rail. When completed, the new asylum will be on an extensive scale, and fitted up to accommodate 900 to 1,000 patients. The ultimate cost, we learn on good authority, will be not less than £150,000.

DIPHTHERIA AT FETTES COLLEGE.—In consequence of the occurrence of two cases of diphtheria at this institution, it has been thought desirable, as a measure of precaution, and to prevent any chance of the spread of the disease, to dismiss the boys for a time. It is to be hoped that a careful inspection of the sanitary arrangements of the building will be made, so as to prevent a recurrence of the disease.

THE LATE MRS. JAMES BUCHANAN.—As a munificent contributor to and founder of medical institutions and scholarships, beside many objects of a humanitarian character, this estimable lady, who has just died in Edinburgh, in her 86th year, deserves more than a passing record. Mrs. James Buchanan was well known as one of the earliest and largest contributors to the new Royal Infirmary, and one of the medical wards there bears her name. Three years ago Mrs. Buchanan presented £1,000 to the University of Edinburgh for the foundation of a scholarship in Midwifery and Gynecology, and had the satisfaction of being visited by the first two Buchanan scholars. During her long life she took a special interest in, and contributed liberally towards, the construction and support of drinking troughs in London and elsewhere. But her philanthropic and humanitarian endeavours to do good were not confined to her own country. She built, and has supported for many years, a school in Swatow, China, for the education of Chinese girls. The Buchanan Institution in Glasgow, which was founded by her husband, received many proofs of her liberality. She built a handsome dining-hall for the boys, in which has been placed a marble bust of herself, by the late William Brodie, R.S.A.

ROYAL INFIRMARY, EDINBURGH.—At a meeting of the managers of this institution, held last week, it was reported that there had been received from the Edinburgh Football Association a sum of £100, the amount allocated to the Infirmary from the money drawn at the various matches for the Charity Cup, presented to the association by Lord Rosebery.

A BELIEVER IN DRUGS.—The subjoined prescription was recently dispensed according to the direction of a medical man by a Glasgow chemist and druggist:—

Sig. A tablespoonful shortly before each meal.

Will any one dare to doubt that there is such a science as that of medicine after this?

IMPORTANT MEETING IN GLASGOW ON THE MEDICAL ACTS AMENDMENT BILL.

A PUBLIC meeting, called in terms of a requisition to the Lord Provost, was held in the Merchants' House, Glasgow, on the 16th inst., to consider the Medical Acts Amendment Bill now in the Commons, more especially in respect to the clauses constituting the Medical Board for Scotland, so as to consist of eight University and three Corporation representatives, thus creating in favour of the Universities a monopoly which would be detrimental to the Extra-Mural Medical Schools by extinguishing freedom in medical teaching.

Lord Provost Ure, who was called upon to preside, explained the steps taken to call the meeting.

Mr. John M'Laren, moved the first resolution:—"That this meeting views with regret the constitution of the proposed Medical Board for Scotland, as from the great preponderance of the University nominees, it is likely to fall prejudicially on the extra-mural school for Scotland." After explaining the nature of the proposed Medical Board, the speaker went on to say that Scotland was not to have a fair representation at the Board as compared with England or Ireland. England was to have a board of 116 members; 8 of these were University professors, and 8 medical corporation. Ireland was to have a board of 11—6 from Universities and 5 from medical schools. Well, Scotland was to have a board of 11, of which the large proportion of 8 was from the Universities, and only 3 from the Medical Corporation. This, upon the face of it, appeared to be unfair. He therefore moved this resolution.

Dr. Leishman took exception to many of the statements that had been made, and said that he could find nowhere in the Bill anything which could create a monopoly not previously existing. There might be something in the monopoly already existing; but there was none that he saw created, nor could he see in any sense that the freedom enjoyed by the extra-mural teachers was to be deprived by this new Board. After going into details, he said he thought the real danger to the Bill in Scotland was a different one from what was stated here—the real origin being a deep-rooted feeling of hostility which existed in England towards Scotch schools, whose surprising success they had been jealous of for many years. He did not intend to move an amendment to the resolution, but would content himself with the remarks made.

The resolution was then agreed to.

Mr. William M'Ewen moved the next resolution, to the effect that as there was no arrangement under which extra-mural schools could be directly represented on the Medical Board, other than through the medical corporations, this meeting is of opinion that the latter should be equally represented with the University as a Medical Board, and at least one half of the Corporation nominees on the Board should be extra-mural teachers.

Provost Brown having seconded this resolution,

Dr. Young moved as an amendment—"That in the opinion of this meeting it is desirable that the extra-academical teachers of Scotland should have a direct representation on the Medical Board of Scotland by three of its own members."

The amendment failed to receive a seconder, and the motion was declared duly carried.

Mr. Stephen Mason moved—"That in the opinion of this meeting it would be unjust to the extra-mural medical schools, and would tell disastrously upon them, that their students should be compelled to pay to the Medical Board a larger fee than the students of the Universities."

Dr. Leishman supported the resolution, which was adopted.

Baillie Wilson moved "That the resolutions that had been put before the meeting should be drawn up in the form of a petition, signed by the chairman of the meeting, and presented to Parliament by the Members for the City."

Mr. Muirhead seconded, and it was agreed to.

Mr. Fleming said it ought also, at the same time, be represented that the meeting was not a fair representative of the medical profession in Glasgow, as it was composed mostly of extra-mural teachers. ("No, no.")

The Chairman: Well, it has been publicly enough advertised, and if the citizens of Glasgow did not turn out in their thousands it cannot be helped.

Baillie Watson moved a vote of thanks to the Lord Provost for taking the chair, which brought the proceedings to a close.

Literature.

QUAIN'S DICTIONARY OF MEDICINE. (a)

MEDICAL literature has received no addition at all comparable to Dr. Quain's "Dictionary" since the appearance of Copland's well-known work, the excellence of which has necessarily excited a considerable amount of expectation in regard to the merits likely to be shown by a new labour projected on similar lines. With the certainty of comparative criticism before him, therefore, it is by no means unlikely that an editor of even Dr. Quain's universally recognised ability may have been anxious for the result of his efforts; and in the exhaustive treatise with which his name will henceforth be always associated, we are able to discern abundant evidence of that careful, conscientious, and thorough workmanship which is impressed on all that emanates from him.

The modern science of medicine borrows largely from the genius of its individual promoters; each physician who devotes himself to the careful analysis of a particular disease or class of diseases succeeds in stamping its treatment for the time being with marks characteristic of his particular views; and in every case where a teacher with a recognised following has thus lent himself to be the enunciator of special views, they have, so long as his influence has continued to exert itself, been followed to the advantage of humanity and the alleviation of suffering. We owe perhaps more than can readily be estimated to Dr. Quain's acute perception of such influences and the bearing they have on the progress of science, and to the facility this perception offers for securing the most able assistance in producing the work already familiar to the majority of medical practitioners. In writing the "Dictionary" Dr. Quain has obtained the service of more than one hundred and fifty of the leading physicians and surgeons of our time, not all of whom, alas! have lived to see the final acceptance of their efforts at the hands of the general profession. The busy hand of death has thinned even the small band associated with Dr. Quain to an all too appreciable extent; and once more we are called on to mourn the loss, emphasised afresh by the lines, in many cases the last they ever wrote, which stand over the names of Parkes, Murchison, Callender, Peacock, Cormack, Lockhart Clarke, Tilbury Fox, Hayden, Leach, Silver, Clover, Irvine, Seaton, Sparks, and Stephen H. Ward. This list indicates, moreover, the length of time during which the work has been in preparation, and from the size and importance it presents it can be readily understood how impossible it must have been to conclude it in any shorter term.

The work is what its name indicates, a *dictionary of medicine*, in which, under the names of various diseases alphabetically arranged, is included a full description of all recognised ailments as regards etiology, symptoms, course, duration and termination, diagnosis, prognosis, and treatment. The characteristic lesions presented under each form of disease are also described as far as is consonant with existing knowledge; and unique importance attaches to the essays of which the volume is in the main composed, from the fact that each bears the signature of the author contributing it, of whose individual research and opinions it is consequently a valuable reflex.

The task of reviewer, when extended to such a monumental production as the "Dictionary," necessarily becomes a most difficult one. When the plan and scope of the book have been explained, there remains but little to be achieved in the direction of legitimate criticism, for the most careful examination of the articles suffices to exhibit no more than points which at the most are matters of personal difference, rather than important departures or omissions. But turning to subjects which have assumed especial prominence in the recent history of medical science, we are afforded opportunity both of observing the minute care with which every matter deserving of notice has been included in the work, and of commenting on the opinions expressed by the authorities responsible for their treatment. Thus, Dr. Ord very fittingly contributes the article on Myxœdema, but owing probably to the revision of his proof sheets having preceded the issue of the "Dictionary" for some time, he confines

the appearance of the disease to adult womanhood. The occurrence of myxœdema in males has now been recorded more than once, and very recently three children have been exhibited in London in whom the appearances of myxœdema were most markedly present. The disease itself is very instructive, and its history more so, as showing the fallacies that lurk under the description of any hitherto unrecognised disease as "new." Under the heading of "Shock," Sir William MacCormac has an able and sufficiently brief essay to convey a lucid and adequate notion of the condition and its consequences; the definition he gives is a very useful one, and though it may be objected that it opens the door too widely to any and every systematic change attended with depression, yet for practical purposes it would be difficult to improve upon it. Sir William MacCormac is not able to add much in the way of pathological details to what is generally accepted on the subject; but he nevertheless faithfully and completely recounts the *modus operandi* of the phenomena associated with shock, involving, as of necessity, the physiological elements of the problem. As aids to treatment, transfusion is recommended in extreme cases of hæmorrhage only, and stimulation of the phrenic nerve and epigastrium by means of electrodes externally is suggested when respiration has ceased or is failing.

Dr. H. Charlton Bastian naturally takes his stand, when contributing under the title "Bacteria," on the ground that the germ theory of disease is materially allied with the question of spontaneous generation, so that the study of the former to the neglect of the latter "can only end in the propagation of vagueness and uncertainty." He further continues: "The real question is not as to the extent or frequency of the co-existence of organisms with local or general diseases, but the much more important one as to the nature of their relation to such processes. If they act as invariable and sole causes, then their presence is a matter of the deepest interest and importance. If, on the other hand, the organisms are not causes, but rather concomitant products, their presence from a purely medical point of view is of trifling importance. The study of their growth and development would in that case be important only as adding to our knowledge of the structural changes pertaining to the diseases in question."

In writing of "Germs of Disease," Dr. Bastian does not hesitate to display his want of sympathy with the modern school of germ theorists; and his faithful agreement with "auto-genetic" principles is equally well, though by no means ostentatiously, advanced. It would, of course, be unfair to expect an authority of Dr. Bastian's undoubted position and tenets to renounce his place as an advocate of special views entirely, and in the articles from his pen scattered through the "Dictionary" we cannot help but admire the excellent good sense and moderation displayed in dealing with subjects respecting which the author of them is so well known to be a holder of extreme opinions. As a summary of opposing views they are most instructive and intelligible, and, as far as such a thing could be under the circumstances, impartial.

The late Dr. Pearson Irvine has contributed a valuable essay on the causes of disease, in which the influences of age, heredity, intermarriage, sex, temperament, climate, and society, town and country, hygienic conditions, occupations, air, previous disease, mental and moral conditions, external physical conditions, poisons, temperature, diet, and epidemics, are considered in detail; and the complementary sections on personal health and public health are provided by Dr. Reginald Southey and the late Dr. Parkes respectively. This last named contribution takes rank as one of the most important in the whole work, being in fact a most admirably compressed *résumé* of the whole science of public health. It can be read with the utmost interest and profit by every medical man, whatever and wherever his practice may be, and will afford him endless and valuable help in the prosecution of professional duties.

Under the heading of "Hospitals, their Administration and Construction," Captain Douglas Galton contributes two very serviceable essays, the terms of which might with advantage be accepted as guiding principles by certain of our greater charities at the present time, and we shall possibly be doing a service to more than one general committee by commending to their perusal the remarks which Captain Galton makes in respect to management of hospitals and the various duties that properly fall to the lot of the medical staffs, matron, &c. The ripe experience gained by

(a) "A Dictionary of Medicine by Various Writers." Edited by Richard Quain, M.D., F.R.S., &c. London: Longmans & Co.

the writer of these articles, and his undoubted eminence in all pertaining to the construction of sanitary institutions, encourage anticipations of the excellence of his papers which they themselves fully maintain.

The diseases of the ear are treated of by Mr. Dalby; while Mr. Brudenell Carter undertakes the section relating to the eye. Epilepsy is described by Dr. Brown-Séquard.

As illustrating the rapidity with which the science of medicine advances the notice written by Dr. Lewis of *filaria sanguinis hominis* may be cited, no later reference than to accounts which appeared in 1877 being made, whereas since that date the life history of the entozoon, though still incompletely known, has been to some extent unravelled. Dr. Quain has, however, added a foot-note to Dr. Lewis's description, in which the researches of Dr. Manson are mentioned, researches which do much to enlighten us concerning the life-history of *filaria*.

A most excellent treatise on "Diseases of the Pleura" is from the pen of Dr. Clifford Allbutt. This work will probably take its place henceforth as the best *résumé* of the subject accessible to the student, and to whatever extent it may be employed in this respect, it will be fully deserving of the importance it attains. The sections dealing with the clinical characters and varieties of pleurisy are especially valuable and interesting, and they bring out the forcible characteristics of Dr. Allbutt as a teacher in a way that commands honest admiration. With a knowledge of the subject of pleurisy gained from careful study of this article and application of the principles laid down in practice the physician may confidently trust himself to do the best possible for such cases as may come within his treatment; and to students the sections cannot be too strongly recommended.

In selecting a few examples from the multitude of articles in the work, we have not sought in any way to indicate that they are instances of excellence elsewhere wanting. On the contrary, it is a characteristic feature of the "Dictionary" that every article in it is both authoritative and exact; the choice of authors has been a happy one, for in every case we recognise the acknowledged connection between the signatures appended and the titles of the sections to which they are attached. We have been compelled by the limits required in a review to instance the character of the whole work by describing the manner in which isolated portions of it have been carried out. In all respects the contents are of the high order of excellence naturally ensured when the pages of a work written by associated authors are throughout enriched with the result of experience gained by the best writers of our age.

To the excellence of Dr. Quain's own labours we need not further allude; those papers signed by him bear witness for themselves; in the numerous shorter contributions for which the reader will silently thank the editor the same carefulness and conscientiousness are displayed with the same gratifying result. The "Dictionary of Medicine," indeed, is a worthy monument of untiring energy, of well-spent labour, and of invaluable research and knowledge.

The necessities of publication have demanded compression of the work by resort to double columns and comparatively small type. The inconveniences thus entailed would be remedied somewhat by division of the huge single volume in future editions into at least two "sizeable" books. Otherwise the "Dictionary" is well produced, the printing is beautifully clear, and the paper excellent.

Since this notice was written, a second edition of the "Dictionary" has been published. The suggestion contained above has apparently occurred to Dr. Quain, for the work is now obtainable either in one or two volumes.

ST THOMAS'S HOSPITAL REPORTS. (a)

[SECOND NOTICE.]

DR. JOHN HARLEY has some very uncommon ideas regarding the close connection between constipation and enteric fever. He says: "Constipation is often the forerunner of enteric fever; I believe I may go even further and state that constipation is occasionally the sole cause of enteric fever." This theory, if popularised, would be a source of considerable increase of practice, and therefore of income

to the attending physician. The author is convinced that many an attack of enteric fever has its origin in constipation; and that death from simple idiopathic constipation is a not uncommon event.

Dr. Harley quotes at some length a case of fecal accumulation in the cæcum, and after stating the points of resemblance and difference between it and a case of enteric fever, he sums up as follows:—"Thus, between two groups of symptoms—the one produced by fecal accumulation and obstruction, and the other by the cause of enteric fever—we fail to find any essential distinction." This conclusion is arrived at by comparing the resemblances and differences in the two cases.

The points of resemblance as stated by him are—1. Disgust of a bad odour; 2. Long continuance of the symptoms; 3. Development of a rose rash.

The differences are—1. Constipation; 2. Perspiration; 3. Temperature.

These differences Dr. Harley speedily disposes of. Constipation, he says, is a very common event in enteric fever. Perspiration, though not common, has occurred in enteric fever in his practice. The normal temperature, he maintains, is sometimes seen in enteric fever, and besides, if the fecal matter had been allowed to remain undisturbed in the intestine for some days longer, severe febrile symptoms would no doubt have been developed.

Dr. J. S. Bristowe relates, most candidly, some mistakes in diagnosis of tumours of the abdomen. Three of these were undoubtedly hydatid cysts, and it was assumed that the other two were of the same nature. Two of the large cysts were successfully punctured. The third large tumour was about to be tapped when it was found that it altered its character under manipulation; it became less and less distinct until—though dulness on percussion still remained—it was decided to defer the operation to a future occasion. It transpired that the patient was in the family-way, and examination with a stethoscope revealed the pulsations of the foetal heart. It is true, says Dr. Bristowe, that "no harm was done, but it is quite clear that I was on the verge of doing harm."

In the second case hydatids were mistaken for abdominal cancer. In the third, hydatids were diagnosed in a case of parovarian dropsy. There is not a truer saying, nor one more applicable to our profession, than that we obtain our knowledge by our mistakes, and the mistakes of others, when so candidly laid before us, are the best calculated to prevent their occurrence in ourselves. Honour is as much, if not more, due to those who have the courage to acknowledge and make known their errors, as to those who only relate brilliant and correct diagnoses.

Surgeon H. G. Armstrong gives the result of nerve-stretching in a case of spinal meningitis. The conditions present were very severe lightning pains, confined principally to the legs and lower parts of the body, though occasionally felt in the upper extremities, and aggravated by any change in the weather; tetanic spasms, produced by pressure on the skin, over the coccyx; inability to walk; entire loss of patella tendon reflex; and complete anaesthesia of both lower extremities up to the groins. Sexual power lost, but not desire.

The operation was performed without the administration of anæsthetic, and was painless. The left sciatic nerve was exposed and stretched.

On the 29th day the patient was free from pain, dressed, and sitting up, and with very slight assistance could walk round the room. Three months after the operation he walked a distance of seven miles before breakfast without fatigue. The result of the nerve stretching has been the recovery of cutaneous sensibility, an almost complete relief from the severe pains and tetanic spasms. The writer considers that this result from operation on one sciatic nerve shows that the stretching acts, not on the periphery, but on the nerve centre.

During the next three months, however, a return of symptoms appeared, and Mr. Armstrong says, "the patient seems to be relapsing into his old condition."

The above contribution, we observe, is not written by a member of the staff, but by the assistant surgeon to the Royal Berkshire Hospital.

The matter contained in the volume, as a whole, is a feeble production for such a large and well-officed establishment as St. Thomas's Hospital.

Correspondence.

THE IRISH COLLEGE OF SURGEONS AND NIGHT LECTURING.

The following letter appears in the Dublin newspapers last week :—

SIR,—Some persons have violated the understood and expressed wish of the College and its immemorial custom in furnishing to the press a statement of the proceedings of the Fellows on the 4th inst., which is not only untrue in fact, but evidently made public with the intention of prejudicing, by a garbled report, the cause of honesty of medical teaching, with which I have been specially associated, and at the same time lowering me in public estimation.

This report states that "Professor Jacob's motion that the College should cease to recognise night lectures was supported by (certain gentlemen named), and was ultimately negatived by a large majority." Sir, it is untrue that any motion forbidding night lectures was offered by me or anyone else to the College, and equally untrue that my motion was supported by the Fellows named, except by silent vote. My motion was as follows :—

"That this College approves of the determination evinced by the Council to ensure *bond fides* of attendance on courses of medical study, but is of opinion that attendance purporting to be given by persons who are engaged during the usual hours of medical study in other engrossing avocations is not a *bond fide* fulfilment of the four years of study required by the General Medical Council, and therefore ought not to be recognised by this College as sufficient qualification for the Letters Testimonial of this College."

You will observe that this resolution simply declared that medical studies supposed to be pursued by students engaged all day in offices and shops are not what the College or Medical Council mean by *bond fide* medical study.

To this resolution the representatives of night lecturing did not venture to offer a negative, but sought to shelve it by acknowledging its principle, and remitting the subject to the Council.

To it the following amendment was moved by a distinguished Fellow—one of the staunchest opponents of night lecturing and all other methods of evading study :—

"That the College, instead of passing any order at the present meeting regarding night lectures, request the incoming Council to forward a copy of the arrangements for securing the attendance of students at lectures and hospital to every lecturer and clinical teacher recognised by the Council with a request that they will aid in carrying out these arrangements."

The sense of this amendment is that the College should take no ulterior steps until it had fully tried the efficacy of the regulation to ensure *bond fides* of study which it promulgated last year. I could willingly have voted for this amendment if I had any faith that the "request" of the College will have effect with the teachers who are parties to the evasion. Failing that hope, I felt it necessary to divide the College on the amendment, with the result that the Fellows, by a majority of 28 to 16, decided to wait, and hope for an honest fulfilment of the Collegiate regulations.

This was a decision in no sense favourable to night lecturing or sham study. This time next year we shall know whether the trust of the Fellows has been misplaced, and, if it shall appear that it has, I shall certainly—if possible—renew the effort to put a stop to sham medical education in Ireland.

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

Obituary.

MR. BENJAMIN BELL, F.R.C.S. ED., M.R.C.S. ENG., OF EDINBURGH.

THIS well-known and respected Edinburgh surgeon has just passed away, at the age of 78. His illness, which terminated fatally, originated in a severe cold, which developed into inflammation of the lungs, and suffering at the time from impaired vital energy and depression owing to the recent loss of his wife, to whom he was greatly attached, he had not strength

to combat the attack referred to, and death ensued on Friday last.

Following the footsteps of his grandfather and father, who were previously surgeons of considerable eminence, the subject of this notice very early in his career showed signs of high talent and future eminence. He rapidly acquired an extensive practice, principally in eye surgery, and soon became one of the most popular surgeons in Edinburgh. In 1835 he was elected a Fellow of the Royal College of Surgeons, and has ever since taken an active interest in the work of the corporation, frequently acting as examiner. Among other bodies with which he became connected were the Edinburgh and St. Bartholomew, the Royal Medical and Medico-Chirurgical Societies, Edinburgh; the Surgical Eye Infirmary, Edinburgh; George Watson's Hospital, and the Asylum for the Blind, Edinburgh. He was also surgeon to the Royal Public Dispensary, and in 1863 an examiner in medicine in the University of Edinburgh, and in 1864 he was elected President of the Royal College of Surgeons, Edinburgh.

Mr. Bell contributed some able papers to various medical journals, among the more important being one on "Cerebral Diseases," which appeared in the *Edinburgh Medical Journal* for 1847, and another, "On the Outbreak of Scarlet Fever in George Watson's Hospital," published in 1851. Besides being well known in his profession, Mr. Bell enjoyed a widespread popularity as a public citizen. He took a deep and lively interest in most of the public questions of the day. His well-known presence will be missed at many a public meeting. His character displayed a happy combination of simplicity and amiability, on the one hand, with a readiness, on the other, to look at new views for himself, and to hold and express his own opinions with firmness. He took a deep interest in every form of mission work, and was largely instrumental in establishing the Edinburgh Medical Mission, and in furthering the training of medical missionaries for foreign service. Mr. Bell is survived by a family of five sons and three daughters, his eldest son, Mr. Joseph Bell, F.R.C.S.E., now practising in Edinburgh, being the only member who has followed the medical profession.

PASS LISTS.

Royal College of Surgeons of England.—The following Members having passed the required examination for the Fellowship, were admitted Fellows of the College at a meeting of the Council held on Thursday, June 14th :—

- Collingwood, David, M.B. Lond., Bedford Street, Liverpool.
- Duncan, W. Archdeacon, L.R.C.P. Lond., Lambeth Palace Road.
- Elam, William Henry, Mirfield, Yorkshire.
- Gross, Charles, L.R.C.P. Lond., Watworth.
- Horseley, V. A. Haden, M.B. Lond., Gower Street.
- Wainwright, Benjamin, M.B. Edin., Belmont, Lee, was admitted to the Fellowship, though not a member.

Two other candidates passed the examination, but being under the legal age (twenty-five years) will receive their diplomas at a future meeting of the Council. Ten candidates failed to reach the required standard, and were referred for twelve months' further professional study.

College of Physicians in Ireland.—At the June examinations the following candidates obtained the licences in Medicine and Midwifery of the College :—

Medicine.

Notices to Correspondents.

DR. J. KINGSTON FOWLER will give a Clinical Demonstration at the Brompton Consumption Hospital to-day at 4 p.m., "On some Points in the Diagnosis, Prognosis, and Treatment of Thoracic Aneurism." Members of the profession admitted on presentation of their cards.

parts and the part beyond was cut off. The sac was next separated from the surrounding tissues, and its neck transfixed and stitched together with catgut sutures, and the part beyond was then cut off. The skin wound was then closed with fishing-gut sutures.

Dec. 30th.—Patient vomited after the operation yesterday at 8 p.m., and again at 9 p.m., and retched and vomited all night. Had suppository of $\frac{1}{2}$ gr. morphia at 8, and another at about midnight. Bowels confined. Temperature last night 98.4°. This morning patient dull and quiet; complains of pain in the abdomen and nausea. Constantly retching. When not disturbed she lies on her back with eyes shut and mouth open, uttering low groans. There is no abdominal tenderness. M. T. 99°, P. 76, urine 1023, acid, no albumen. Ordered nutritive enemata every four hours.

31st.—No vomiting or retching since yesterday. Abdominal pain and tenderness greatly relieved. Had a natural action of the bowels early this morning (in the night) for first time since operation.

Jan. 1st.—Enemata discontinued. M. T. 98°, P. 84. Going on well.

2nd.—T. 98°, P. 84. Bowels confined. No pain or vomiting. Wound dressed, sutures removed, healed by first intention.

4th.—Pad and bandage reapplied. Wound well. T. 67°. Had a small motion of the bowels attended at the time with a little abdominal pain. No nausea or vomiting.

5th.—T. 98°, P. 80. Slept fairly well last night. No abdominal pain or tenderness. No nausea or vomiting. Has frequent rattling cough, which she has had for the last four months.

Left the hospital Jan. 19th, 1883.

CASE IV.—Strangulated femoral hernia—Sac opened and removed—Cured.

H. D., *et.* 50, married. The rupture came down on Monday (25th). Bowels not open since that day. Sickness commenced on Wednesday night and has gradually increased. The vomit is now offensive and faecal, and patient is sick after everything she takes. Patient looks emaciated. Tongue dry and furred. Tumour size of an orange, in Scarpa's triangle, R. Hernia formed 7 years ago, as result of strain in lifting heavy weight. Never worn a truss for it. Usually about size of a hen's egg, and generally disappearing at night.

Dec. 30th, 1882.—Operated upon on Saturday, 30th December, 2 a.m. The patient came in at 11.30 a.m. Gimbernat's ligature divided, taxis again failed. Sac opened, stricture at neck of sac tight. Sac contained a large piece of omentum, and a small portion of bowel, which was of a livid red colour, and was not further altered around the seat of constriction than elsewhere. Bowel returned. Omentum ligatured in two portions and removed; the sac was then stitched with a catgut suture a little below the neck, and the body of the sac removed. Wound brought together with fishing-gut sutures and dressed with terebenthine, oil, and cotton-wool.

31st.—She passed flatus. P. 100, T. 99.2°. No tenderness of the abdomen, wound looking quite healthy. Not been sick. Nutritive enemata have been given as she is so very feeble.

Jan. 1st.—T. 99.2°, P. 90.

2nd.—Wound dressed and is healed. Nutritive enemata discontinued. T. 98.4°, P. 87.

3rd.—T. 96°.

4th.—No sickness or pain since operation. Bowels not yet moved since operation. T. 98.4°, P. 90.

Left hospital Jan. 19th.

Transactions of Societies.

ACADEMY OF MEDICINE IN IRELAND. PATHOLOGICAL SECTION.

A MEETING of the Pathological Section was held on Friday evening, April 4th, in the Albert Hall, Royal College of Surgeons.

LIVING SPECIMENS.

The following specimens were exhibited:—

Dr. J. S. M'ARDLE—Deformity of the upper extremity, and arrest of development following injury of the median nerve. Twenty years ago the patient, who is now in his twenty-sixth year, sustained a fracture of the humerus and dislocation of the elbow. Paralysis followed, and after the reduction of the dislocation and repair of the fracture, contraction of the flexors gradually set in. At present the temperature of the hand is 2° below that of the sound side. The forearm is two inches shorter, and the wrist $\frac{1}{2}$ inches less in circumference. Cyanosis is always present on the affected side. A neuroma is present in the antecubital fossa,

pressure on which causes numbness in the arc of the median nerve. The nails and skin are all ill-nourished, and a cicatrix on the flexor aspect marks the point at which bullæ have appeared since the injury.

Mr. BENSON—Myctatopic conjunctivitis.

Mr. COPPINGER—A patient suffering from hydatid disease of the femur.

SPECIMENS BY CARD.

The following specimens were exhibited by card:—

Mr. ABRAHAM—Ulcerations of the intestines, associated with malignant disease of the cæcum, with microscopical mountings.

Mr. COPPINGER—Portions of bone affected by hydatids removed from the femur of the patient exhibited.

Mr. STOKER—Thrombus of the pulmonary artery.

Mr. ABRAHAM—A single kidney from the body of a man; the left kidney, its vessels and arches were congenitally absent.

Dr. L. MATUREN—(1) Congenital deformity of the forearm and hand; (2) Aneurism of the ascending aorta.

Mr. CORLEY—Impacted alimentary bolus. Patrick Sheridan, *æt.* 49, married, residing at 63 Church Street, owning a lodging-house, was brought to the Richmond Hospital on the 14th April last at 11.15 p.m. On admission he was quite dead. The following facts were elicited from his wife at the coroner's inquest on the 16th:—Deceased came home on the evening of the 14th considerably under the influence of drink, and sat down along with several others to eat his supper. After having eaten quietly for some minutes, he suddenly attracted the attention of one of the others by giving a violent smothered cough. On looking round she said she saw him all black in the face, and staring at them. She ran over and hit him on the back, and succeeded in getting a small piece of the meat (oorn beef) out of his mouth, but without any effect on him. He was then brought to hospital. The piece of meat did not enter the larynx, but was firmly impacted into the pharynx, in this way completely occluding the opening of the larynx.

CONGENITAL MALFORMATION OF THE THORAX.

Dr. E. H. BENNETT read a paper describing the characteristics of a congenital malformation of the thorax, in which the anterior extremities of a single rib failed to reach its cartilage, and there existed in consequence a depression of the thoracic wall on one side, while the cartilages attached to the corresponding parts of the opposite side were hypertrophic, and projected as tumours in front of the level of the sternum. Having referred to the description of this malformation given by Otto and Rokitsanski, in which no mention is made of excessive development on the side opposite to the defect, Dr. Bennett showed a preparation which presented the characters mentioned in a most marked degree. He pointed out the importance of a knowledge of this malformation in relation to diagnosis of lesions of the costal cartilages, illustrating the point by the facts of the case from which he had obtained the specimen, and from two other clinical observations. In all three cases injuries had occurred which suggested that the thorax had been crushed, and the diagnosis had been erroneous in one—that from which the specimen had been taken.

The SECRETARY (Dr. Bennett) read for Mr. J. Davidson a paper on

THE INFLUENCE OF FRACTURE ON THE GROWTH OF BONE, in which the author recorded the results of his observations on the fracture of the long bones of the lower animals, chiefly fowls, in which the injury occurred during the active growth of bone. Comparison of the injured bone with their fellows showed that there existed a marked increase of size in all dimensions, the bones being heavy and longer on the fractured side.

Dr. FRASER, STOKER, CORLEY, M'SWINEY, BENNETT, and ABRAHAM discussed the foregoing paper, and expressed their sense of the exactness and care displayed by the author in his investigation.

Dr. COPPINGER read a paper on

HYDATID DISEASE OF THE FEMUR,

the patient and parts removed which established the diagnosis having been exhibited to the meeting already by card. He alluded to the infrequency of the occurrence of hydatid tumours in the human subject in Ireland, notwithstanding the known prevalence of the echinococcus disease in sheep,

mentioning that hydatid tumours even in countries where the affection is comparatively common, seemed scarcely to invade the bones, and that no instance of the disease in the bones had up to the present been recorded in this country. The patient (exhibited, and from whom the cysts and portions of bone had been removed), had been under observation for three years, having been admitted to the Mater Misericordias Hospital on receipt of a spontaneous fracture of the upper third of the femur, due apparently to its invasion by the parasite. The disease was not diagnosed until Mr. Coppinger had made an attempt to excise the patient's hip-joint, and discovered a large cavity in the dilated upper part of the femur, containing hydatid cysts and loose pieces of bone studded over with small echinococci vesicles. These (some of which were shown as microscopical specimens) exhibited the characteristic features of echinococcus cyst, selicis, &c. The complicated excision was abandoned, but the great trochanter was removed with a saw, and the cavity finally laid open and syringed out with chloride of lime solution. It was then ascertained that the shaft of the femur was firmly connected with its neck by means of the thin walls of the bony tumour, and it was hoped that, the disease having been apparently removed, the space would fill by granulation bone from below. It had since become much smaller, but the patient's condition was so unsatisfactory, even now after treatment extending over nearly two years, that another operation would be performed for the purpose, if possible, of eradicating the disease. The limb was three inches shorter than its fellow. The man was obliged to have a crutch, being unable to rest his weight upon the limb, and the wound, which was still open, led through a narrow slit in the bone into a cavity in its centre, extending upwards into the femoral neck, as well as downwards into the shaft of the femur. Although this cavity was daily washed out with carbolic and boro-glyceride solution, and although all disease was apparently removed, collapsed cysts and shreds of membrane still escaped from it occasionally, proving that the peculiar disease caused by the presence of small exogenous cysts in the cancelli of the bone had not yet been eradicated.

Mr. THORNLEY STOKER read notes of a case of

THROMBOSIS OF THE PULMONARY ARTERY,

occurring in a boy subsequently to the removal of the thyroid body, and proving fatal. He exhibited the specimen.

Dr. BENNETT expressed his doubt as to the character of the thrombus, regarding it as a post-mortem production, and a discussion followed, in which Drs. THOMSON, CORLEY, KIDD, and ABRAHAM took part, and Mr. STOKER replied.

Dr. R. A. HAYES exhibited on a screen with the lantern photographs of the microscopical appearances of the normal and diseased tissues, and explained the details of the process.

The Section then adjourned.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, APRIL 12, 1883.

B. WALKER, Esq., President, in the Chair.

Dr. PORTER showed

THREE CASES OF FRACTURED PATELLA

As illustrating good results from very simple treatment. One case had stood the test of fifteen months, and a second of nine months; the former was following his occupation as a groom, and riding constantly, while the second case referred to had been able to continue her work as a file cutter, and walk without any assistance whatever three months after the accident. The first case was a transverse fracture from direct violence, there was less than half inch separation on admission into the Sheffield General Infirmary, and not very much swelling. Union in this case appeared to be either by bone or very firm fibrous tissue. The second case shown was one of transverse fracture from muscular action, in which there had been quite three-quarters of an inch separation at the time of admission, and a great deal of swelling of the joint. In this case there certainly appeared to be osseous union. The third case had only been done about five months, but though he had not been able yet to resume work there was no

reason for supposing that the result would be in any way inferior to that obtained in the other two cases. There was about three-quarters of an inch separation of the fragments at the time of the accident, and a great deal of swelling, the fracture was a transverse one and produced by muscular action. In all three the same plan of treatment had been adopted, firm compression of the knee with an ordinary bandage, and the application of an ice bag to reduce the swelling at once and ensure early apposition of the fragments. The swelling subsided in from twenty-four to forty-eight hours, and the leg was then put up on a straight wooden back splint with foot-piece, the fragments being brought forcibly together by pieces of strapping placed obliquely and covered by a figure of eight bandage over the knee. This splint was kept on for three months, and a gum and chalk knee-cap worn for two months longer. Dr. Porter attributed the good results in these cases to the compression applied to the knee at once to reduce the swelling and enable the fragments to be brought together. He mentioned that he had seen the first case in which wiring the two fragments together had been tried, but he was bound to say that he did not think the result was superior to that obtained in the two first cases he had shown.

A CASE OF STRANGULATED UMBILICAL HERNIA.

Dr. MORTON related particulars of a case of strangulated umbilical hernia on which he had operated with success. The subject of the hernia was a short corpulent widow woman, *æt.* 64, who had suffered from it and worn a truss many years. The hernia being about the size of a large orange, and reducible, but occasionally with some difficulty. On March 7th, 1883 the protrusion could not be returned by ordinary taxis. Opium was given, and subsequently an enema of castor oil. No symptoms of strangulation appeared until March 12, when violent pain and stercoraceous vomiting set in. Operation was performed on the following day. The patient having dyspnoea and feeble heart chloroform only sparingly administered. An incision with scalpel, one and a half inches, made through integument above tumour, and deepened until the upper edge of ventral opening was felt by index finger. A probe-pointed herniotomy knife was then insinuated between parietal wall and peritoneum, and the edge notched upwards, widening opening sufficiently to allow the return of intestine, which immediately receded by gentle pressure, leaving the sac quite empty and flaccid. The peritoneum was intact. A wire suture applied, lint pad and belt bandage secured all. Recovery rapid.

Dr. MORTON on a

CASE OF HYDROCELE.

R. F., *æt.* 29, a strong healthy married man, stated he first noticed swelling eight years ago. Might have been induced by saddle when riding. He had been tapped three times, and an injection used once. February 24, 1883, the left tunica vaginalis was found distended, sixteen ounces of serum withdrawn by trocar, and then two fluid drams of tr. iodi injected. The patient felt faint but able to walk home, and two days afterwards resumed work. He came under notice again March 25, the fluid having collected. Eight ounces taken away, and the treatment suggested by Mr. Walker reported in *Brit. Med. Jour.*, March 17th, was tried, namely, injection of lig. ergotæ ext., P. B. two drachms. Very little pain and but slight inflammatory action followed. There was no accumulation of serum when seen April 3rd.

Dr. DYSON on

SOME CASES OF FEVER ACCOMPANIED BY HERPES OF THE PHARYNX.

which will be found on page 532.

THE zymotic death-rate continues to be exceedingly low in all the large towns except Glasgow, where it attained last week to the almost epidemic rate of 7·3 of the entire mortality. In the other large towns the death-rates from these diseases were—Liverpool 5·5; Newcastle-on-Tyne 4·9; Sheffield 3·7; Bradford 2·8; Manchester and Brighton 2·6; London 2·4; Dublin 2·1; Edinburgh 1·8. The 35 deaths from diphtheria in the thirty-one towns included 22 in London, 5 in Glasgow, and 4 in Birmingham. Small-pox caused 3 deaths in London, 4 in Newcastle-upon-Tyne, and one in Liverpool.

THE UNQUALIFIED ASSISTANT SYSTEM
AND THE
ILLEGAL SIGNING OF DEATH CERTIFICATES.

(Concluded from page 514.)

THE RISE AND PROGRESS OF THE SYSTEM OF EMPLOYING
ASSISTANTS.—(Continued.)

It may be strongly suspected that not only good training of a systematic kind is impeded, but also that harm is done by the requirement of the larger number of labours to be attended, for the necessarily hurried visits to the homes of out-patients in adverse circumstances leads to many bad habits, and especially to an insensibility to danger fatal to an accoucheur's usefulness in after-life.

Should an unexpected death occur to mother or child during the attendance of students, they cannot, of course, sign the certificate, and have to apply to the qualified obstetric officer of the school. He gives a statement of the facts as reported to him, and this has often been accepted by the registrar of deaths (an instance has already been given) in lieu of certificate. But the Registrar-General declines to sanction the custom, and schools are placed in much difficulty. The medical officer of health for the one parish of Bermondsey, Dr. Dixon, reports that six of the uncertified deaths in one year (1881) were those of persons attended by students of a neighbouring hospital.

It is scarcely necessary to say that the attendance on mothers and infants by the unqualified assistants of the midwifery departments in responsible charge causes frequent scandals and dissatisfaction among the general public. And what is of almost equal importance, it encourages students to take unqualified assistantships, and hampers schools in their aims at discouraging the practice.

All this evil would be avoided if the women were not attended till after the students had been proved fit to practise by their final examination.

General Remarks.

Although it is a moral offence to procure an unregistered person falsely to pretend to be a duly qualified medical practitioner, which is done when he is deputed to treat the sick as the representative of a duly qualified practitioner—and a moral offence as great as the false pretence itself—and although it is an equal injustice to the sick and to the profession, yet no legal penalty is attached to it. Legislation, which would make the offender liable to summary conviction, and to fine or imprisonment, is desired by many persons very competent to form an opinion. One who has long practised in the midst of a mass of unqualified assistants in Staffordshire states, as his opinion, that "what would tend more than anything else to stop unqualified practitioners would be to make it a legal offence for any qualified man to employ one unqualified to represent him—to fix the criminality on the *real culprit*, who benefits by such transactions."

The intentions of the Registration Act are evaded very frequently, as a consequence of the employment of unqualified assistants by registered practitioners; and the check upon the procurator above characterised, which it might have been supposed the registrars could impose, is unavailing. A letter to the Council from Dr. Ogle, supplementary to the remarks printed on pp. 66-68, points clearly to the difficulty now existing, and suggests a means of remedying it, which appears worthy of the consideration of the Council. He recommends that a form of certificate of death should be settled by the Registrar-General after due consultation with the Medical Council, and that the use of this form should be made compulsory.

An injury is inflicted on Friendly Societies and similar institutions by certificates of illness being signed by procurator of unregistered person. The pecuniary loss is stated to be large; but it may be remarked that the remedy lies in the hands of the managers of those Societies, as they can decline to receive certificates except from duly qualified medical practitioners.

The action of the Council in their last session, in regard to the employment of unqualified assistants, seems to be not generally known or understood. If it could be made more public I venture to think good would result.

From the letters of several employers it seems likely that to be restrained in their employment of unqualified assist-

ants will be some inconvenience to them, unless a compensation be provided by an increased supply of properly educated men to act as qualified assistants.

Mr. Spanton, of Hanley, who employs only qualified assistants, says: "To get rid of unqualified assistants you must, I think, make qualified men what the term implies, and not merely 'passed' men. This can be done only by some term of pupillage early in the career—say a year with a hospital surgeon in general practice, or at a provincial dispensary before going up to London, or a certificate from someone properly authorised to give it, that a term of real practical instruction in the small details of practice has been properly spent." Later on he says: "The most feasible and most useful plan would be to require evidence from a properly authorised person that a certain period had been passed by the candidate as pupil, or as assistant, to a medical man (after qualifying) before allowing him to register, leaving him free to elect which he prefers; though I should like to see the pupillage compulsory."

Remarks by Dr. W. Ogle (Assistant Registrar-General) on a Passage on Page 71 of the foregoing Statement.

The statement that the registration office encourages violations of the Registration Act by its unwillingness to prosecute, is a charge which I venture to think should not be made by the Committee of the Medical Council, unless they have evidence to substantiate it. Let it at any rate be stated what were "the cases reported in the daily papers," by which the Committee are led to believe that such a charge is true. To the best of my knowledge and belief, the charge is entirely unwarranted by facts. Many prosecutions are yearly instituted by the Registrar-General's authority, and, as a matter of fact, I only know myself of one single case since my acquaintance with the office, where there was reason to believe that the Act had been violated, and yet the Registrar-General, on complaint being made, declined to prosecute. Of that case, and the reasons for such refusal, I shall have something to say presently. There have, however, been many cases where complaint has been made to the Registrar-General, and he has declined to authorise a prosecution, simply because the alleged offence was not a violation of the Act.

These are the cases which newspaper writers, without troubling themselves as to the law on the matter, report as "refusals of the Registrar-General to enforce the Act," and which the Committee also appear to accept as such without further investigation.

By the Registration Act, a registered medical practitioner who has been in attendance on a person in his last illness in case of that person's death, bound to give a certificate, stating, to the best of his knowledge, the cause of death; and the Registrar-General is bound to furnish such registered practitioner with printed forms of certificates. But there is not a single word in the Act saying that a registered or unregistered practitioner, or, indeed, anyone else, shall not give a certificate of cause of death in cases where he was not in attendance or which he never saw. So far as the Registration Act, and therefore the Registrar-General, is concerned, the ordinary proceeding of a "cover" in signing a certificate of cause of death when he never visited the patient himself is not an illegality. It may be "infamous conduct" on the part of the "cover," as the Statement argues, as I think, with justice, but it is not illegal; and it is the business and in the power of the Medical Council to deal with "infamous conduct" on the part of registered medical practitioners, and not the business nor in the power of the Registrar-General.

It sometimes, however, happens that the "cover" does break the law by stating that he has been in attendance upon the deceased, when in reality he never visited him. When such cases are reported by complaints to this office the Registrar-General invariably, so far as my knowledge goes, sanctions a prosecution. And the consequence of this action on the part of the Registration Office has been as follows: The "cover" leaves the spaces, in the form of certificate issued by this office, relating to attendance on the deceased, blank, or prints and uses a special form of certificate of his own, in which nothing is said as to attendance on the deceased. There is nothing illegal in this. Legal opinion has been asked for by this office from the proper law officers, as to whether a registered medical practitioner is bound to use for his certificate the form which the Registrar-General is bound to supply him with, and the answer has been that

URIC ACID: ITS PHYSIOLOGY AND ITS RELATION TO RENAL CALCULI AND GRAVEL. (a)

By ALFRED BARING GARROD, M.D.,

F.R.C.P., F.R.S., &c.,

Consulting Physician to King's College Hospital, London.

LECTURE II.—(Continued.)

LET us now study more closely these two forms of renal calculus, and let us begin with the more simple kind. I will select one which is very minute indeed, a mere point of matter; this, when placed in a small cell under the microscope, presented an appearance which is exhibited in the enlarged drawing on the screen.

It is seen to be irregular on its surface, as if composed of a number of little beads or grains aggregated together. Let us now watch the result of putting into the cell a few drops of a solution of carbonate of lithium. After a few minutes' the superficial beads became more or less transparent, and exhibited, in many instances, the appearance of small cells which had been denuded of their contents. The little calculus soon has a translucent ring around it, which becomes broader and broader as the action of the carbonate of lithium spreads, the opacity of the calculus remaining in the centre only. Under the continued action of the lithia-salt, this last remnant of opacity also disappears, and the whole calculus is reduced to a translucent substance, which has the appearance of being made up of a great number of little vesicles. If polarized light be employed, this is seen to contain matter having a crystalline structure; but the still further continued action of the alkaline fluid ultimately removes this too, and the calculus is then seen as a mass apparently made up of colloidal matter in a more or less membranous shape.

In these experiments, as well as in those made on the spheroidal cells of the urinary excretion of the lower animals, I have always employed a solution of carbonate of lithium, which has the advantage of not injuring the membranous structure of the substance; whereas Dr. Carter, in his examination of calculi, appears to have used the solution of potash of the *Pharmacopœia*—a preparation which tends to destroy this structure, and to mask, to a great extent, the character of the changes that occur.

Let us first imagine that we put a particle of the white excretion of serpents on a microscopic slide, in a drop of alcohol, which does not alter the spherules; and, after covering it with a thin glass disc, examine it carefully. Then are seen spherules of varying size, some smaller, and some smaller still, till at length a size, is reached which seems to be the smallest which they are capable of assuming. Next, let us place a moistened finger upon the thin upper glass, and rub it upon the powder for a few seconds, using a fair pressure; then on re-examination under the microscope, the whole of the spherules have disappeared, and in their place are seen innumerable irregularly-rounded particles of a pretty uniform size.

If, instead of using pressure, we allow the alcohol on the slide to evaporate, and introduce a drop of a solution of carbonate of lithium, and then watch what follows, we shall see that the outlying spherules in the field are usually the first to be acted upon, and exhibit the following appearances: After a few minutes, some of the spherules show a transparent line around them, which, on close examination, is seen to be composed of transparent beads; this ring grows larger and larger, so that in a short time, no opacity remains, save in the centre of the spherule. As time goes on, with renewed application of the alkaline solution, the dark central mass gets smaller and smaller and at last altogether disappears, our original spherule being changed into a round membranous mass, without definite structure, containing crystalline matter which powerfully polarises light, which matter also in turn gives way under long-continued action of the lithia solution.

If we compare this description of what I may call the "dissolving view" presented to us by the changes in the normal spherule of the bird or reptile with that before given of those which occur in the small or rudimentary calculus, we cannot help being struck by their close resemblance; in fact, whatever differences there may be

seem to be little more than differences of degree. Surely this must make us reflect on the possibility of there being a close relationship between the two, and may fairly suggest to us the question whether the rudimentary uric calculi found in man may not be merely aggregations of spherules—the product of the original cell-formation of the uric acid. In the case of the bird and reptile we are sure that the spherule cannot have been deposited from uric acid previously dissolved in the urine, seeing that there is no such fluid to dissolve it; and it may be that, in the case of man also, the individual components of these calculi are simply the original cell-formations of uric acid, which have become somewhat altered in chemical composition, and rendered less soluble. If this be true, and if we can show that these rudimentary calculi are not produced by the precipitation of uric acid from the urine, we must at once remove them from that class of deposits which are called sand or gravel, seeing that these latter, whatever their size, have an altogether different structure. It is to the spherular grains and the more complex structures that I shall confine the name of renal calculi.

Dr. Prout, in his description of an uric acid calculus, speaks of the centre of uric calculi as non-crystalline in character.

In several renal calculi which I have examined, I have found some spherular bodies—masses of irregular shape, resembling much the partially broken-up pyramids into which the spherules of the excretion from reptiles and birds frequently split when carefully rubbed and only partially disintegrated. I have also found crystals of oxalate of calcium, many of them octahedral in shape. From these examinations, I have formed the opinion that the appearances in the nucleus may arise from a slow alteration taking place in the first-formed or spherular urates, by the action of the fluid urine upon them, causing the gradual decomposition of the original ammonia salt, and an increase of its insolubility, leading, also, to the subsequent production of oxalate of calcium, which, we know, is often the result of action of a ferment on uric acid.

I may here state that I have often found that the excretion of reptiles and birds, when acted on for a long time by weak solutions of carbonate of lithium, leave a residue consisting of the organic or colloidal matter, mixed with crystals of oxalate and carbonate of calcium, and that these are often in the spherular form.

If, instead of a very small and rudimentary calculus consisting merely of an aggregation of grains, we take one of a larger size and more complex structure—one, for example, one-eighth or one-sixth of an inch in diameter—we find that, around this granular central nucleus, layers are arranged in concentric order, that is, the calculus becomes laminated, the number of layers depending greatly on the length of time during which it has been exposed to the action of the urine. These layers vary much in thickness, and also in colour, and probably are most of them originally composed of some urate rather than uric acid itself. The subsequent action of an acid urine on a deposited layer of an urate would often slowly reduce the urates into a state of free uric acid. In examining renal calculi which have this laminate arrangement, I have frequently found the central nucleus almost devoid of colour, and very different in this respect from the surrounding layers, which are generally of a pale or dark fawn colour. What is the cause of this peculiarity of the nucleus? The only explanation which at all satisfies my mind is, that the nucleus-granules have never been in a state of solution since they were formed in the kidney-cells, and, therefore, have never become re-crystallised with the colouring matter of the urine; in fact, that they are in a condition very much like that of the renal spherules of the lower animals. The colour of the layers is not at all difficult to explain; for, whenever uric acid or urates are deposited from solution, they invariably take with them the colouring matter of such solution, which becomes intimately united with the crystalloid, in an altered shape. Thus it appears to me that we have a rational explanation, both of the pale appearance or absence of colour in the nucleus and of the colour of the different layers which surround it.

Influence of Diet.—There can be little doubt that the occurrence of gravel and calculus is largely influenced by the diet; but on this subject I feel sure that the opinions frequently held are not altogether correct, and require to be reconsidered. As we shall find in our next lecture, that a gouty diathesis is so potent in the production of the diseases under review, it will be quite safe, in so far as the discussion of food is concerned, to assume that what tends to produce

(a) The Lumleian Lectures for 1883. Delivered before the Royal College of Physicians of London.

gout tends also to develop calculus, and that the diet which is of avail in the treatment of the one disease is equally so in the management of the other. It will be desirable to turn our attention to the principal groups of aliments, and ascertain what influence they have, not only upon the formation of uric acid, but also upon its condition with respect to solubility.

1. *Sugar*.—Much has been said about sugar as an article of diet in uric acid affections; and of what has been said, much is certainly devoid of foundation. Nothing is more common than for a patient to tell one that he always avoids sugar, and looks upon it as a poison to the system, and a principle to be altogether shunned.

How do the facts stand with regard to sugar?

There are three kinds, which are commonly met with in different articles of food: (a) *Cane-sugar*, which, although it is most commonly seen and most largely cultivated as a separate article of diet, is yet much less common than (b) *Glucose*, or grape sugar, which so extensively pervades the vegetable kingdom; and (c) *Lactose*, or milk-sugar, is a third kind, which gives the slight sweetness to the milk of different animals. These three forms of sugar are very closely allied to each other, both in physical properties and in chemical constitution. Cane-sugar, when warmed with a trace of mineral acid, is resolved into glucose, and undergoes the same change when taken into the stomach. Grape-sugar is also closely allied to starch; and the latter, under the influence of many chemical agents, and when taken into the alimentary canal, passes through the stage of dextrine into that of glucose. Both cane and grape-sugar are prone to undergo the alcoholic fermentation, and to be resolved chiefly into carbonic acid and alcohol. Milk-sugar, or lactose, undergoes the alcoholic fermentation only indirectly, and much less quickly than glucose; still, milk does ferment with yeast. On the other hand, lactose is apt to undergo another change, and to be directly converted into lactic acid, with the production of some butyric acid.

The most common of the non-nitrogenised principles contained in food is starch, seeing that it forms seventy per cent. of wheat flour; and almost the whole of many of the simple amylaceous articles of food, as rice, maize, arrowroot, tapioca, sago, &c.; also of the potato, turnip, carrot, and so on, when these latter are dried. It can be shown that, when taken into the alimentary canal, starch is soon changed into glucose-sugar by the action of the saliva and pancreatic juices; and, when cane-sugar is taken, the same change ensues—so that, however carefully sugar is avoided as an article of food, it is still abundantly formed in the canal when amylaceous matters are eaten; and the result is the same whether a pound of starch in any of its dietetic forms, or a pound of cane-sugar, be taken, glucose-sugar being formed in both instances.

There is a very popular idea that sugar causes what is termed acidity, and hence it is scrupulously avoided by many. Is this true? Between two and three years ago I was much struck at seeing an American surgeon of great repute, putting lump after lump of white sugar into his tea, and I asked him why he did so. He told me that, in the States, it is a common habit to take sugar thus as a preventive of heartburn, and that he took it for that purpose. His answer made a strong impression on my mind, and since then I have often questioned dyspeptic patients as to their experience on this point. At first nearly all exclaim, "of course sugar causes acidity," but as yet I have failed to find anyone who could assure me, from personal experience, that the eating of lumps of ordinary white sugar produces more so-called acidity than taking any other article of diet. Let us see what has been found experimentally with regard to the influence of sugar on the production of uric acid. Böcker says that the effect, in man, is to lessen the quantity of that principle, and Bischoff and Voit have proved that, in dogs, starch produces the same effect on the urinary excretion as sugar, so I think we may say that there is no increase in the uric acid when sugar is taken. When, however, sugar is given to an animal along with a fixed amount of nitrogenised food, it causes a marked diminution of the eliminated nitrogen and, at the same time, a great augmentation of the weight of the animal; so that there is no doubt as to the influence of sugar and amylaceous matters in fattening; they act in fact by preserving the protein compounds from undergoing such rapid metabolism as otherwise would take place.

The same negative result, as to the acidity of the urine, has been observed in the case of fresh fruits, nay more, Wöhler has found that cherries, apples, and strawberries either diminish the acidity or even cause alkalinity, through

the conversion of the vegetable salts which they contain into the carbonates of the same bases. As we proceed we shall meet with other proofs that sugar does not necessarily influence the production of the diseases under consideration.

It is necessary to investigate the influence of the most important of the constituents of the different alcoholic beverages upon the urinary secretion, and first let us take alcohol itself:

1. *Alcohol*.—According to the experiments of Böcker and Hammond, the uric acid appeared to be slightly increased in quantity by the taking of alcohol; but even this is matter of doubt and, on the whole, its influence on the production of that principle may be regarded as inconsiderable, nor is there any reason to suppose that it sensibly affects the acidity of the urine.

2. *Distilled Spirits*.—In the various distilled spirits, as brandy, rum, gin, and whisky, there are found very small quantities of different ethers and essential oils, which, doubtless, modify to some extent the action of the alcohol on the different functions, but cause no essential alteration in the constitution of the urine.

3. *Wines*.—The various kinds of wines, although they possess one character in common, viz., the presence of ceanthine ether, still differ from each other in many important particulars, so that, to ascertain their properties and their influence upon the production of calculus and gout, we must group them into at least two classes.

In the first division we have the natural light wines, in which the alcohol is small in quantity, not more than 10 per cent., and in which the fermentation has been allowed to proceed till the whole of the sugar has become destroyed. These wines are rich also in acid tartrates, and in racemates.

In the second division we may place the Peninsular wines of Spain and Portugal, the wines of Sicily and Madeira, and Champagne and the other sparkling wines. These all contain a considerable quantity of sugar, owing to the arrest of fermentation which has been induced by the addition of distilled spirit, for it must be remembered that the process of fermentation is stopped when 12 per cent. of alcohol is developed. In this class of wines there is a marked absence of the vegetable salts, which become insoluble on the addition of the spirit, forming the well-known crust deposited on wine casks, which is known in commerce under the name of argol.

It may, as I believe, be confidently asserted, with respect to gout, that, with an absence of alcohol in any shape, coupled with an absence of hereditary predisposition derived from alcohol-drinking ancestors, the disease would be practically unknown; and that Noah, in planting his vineyard and drinking the wine thereof, laid the foundations of much misery for his descendants.

It is most essential to separate the different kinds of alcoholic beverages from each other in estimating their tendency to produce disease. Thus alcohol in the form of distilled spirits, although, when taken in excess, it causes serious mischief, injuring the liver, kidneys, heart, and other organs, still has little or no power of producing the uric acid diathesis, or, at any rate, the gouty development of it. In spirit-drinking countries, or among spirit-drinking families, gout is unknown. Look at Scotland and its whisky-drinking classes—and they are said not to be too sparing in their potations—the disease is practically absent; hardly ever seen in the hospitals. Look at Poland, where they drink a kind of arrack; the same holds good. A physician from Warsaw, to whom I was once showing some cases of gout in my hospital wards, said that he was peculiarly interested in them, as it was the first time he had ever seen examples of this disease; and, in connection with this, I may mention that, not only does spirit by itself fail to cause gout, but the combination of spirit and sugar is harmless in that direction; for toddy, I am told, is usually a sweet beverage.

When, however, we investigate the influence of wines, we shall find a different result. Drinkers of the common light wines, such as the red Bordeaux and the Rhine wines, suffer but little; while among the same nations, those who indulge freely in beer, as do the inhabitants of Berlin and Munich, for example, are by no means free from evil results to their health.

Experience shows, with respect to the influence of the different kinds of wines, that the natural light wines, in which the alcohol is small in amount, while there is an almost complete absence of unfermented matter, which contain also a considerable quantity of acid vegetable salts, are little liable

either to produce gout, or to lead to the formation of calculus or gravel.

On the other hand, the Peninsular wines and those which resemble them, which are stronger in alcohol, contain much unfermented matter, and are almost devoid of the vegetable salts, have great gout-producing power, and, at the same time, lead readily to a condition of urine favourable to the production of gravel and calculus.

4. *Malt Liquors—Ale, Beer, Stout, and Porter.*—We come, lastly to the malt liquors—ale, beer, stout, and porter. In the manufacture of all of these, the fermentation is arrested at a particular period, so as to leave what is called a "body"; in that they are but partially fermented; they resemble, therefore, the Peninsular wines. Now, from my own experience, and I believe it is also the experience of all who have attended to the subject, I can confidently assert that these beverages have a great tendency to produce the uric acid diathesis. Compare the hospitals of Edinburgh and Glasgow with those of London. In the former, gout is scarcely known; in the latter, the disease is common, the difference, as I believe, being chiefly due to the different beverages drunk by the working classes of the two countries; it is, in fact, the difference between whisky and malt liquors.

It cannot be the alcohol alone. This, I believe, can be fully and satisfactorily proved, seeing that large groups of people, whose custom is to drink freely of distilled spirits are yet free: instances are to hand in Scotland, Sweden, and Norway, and Poland. It cannot be the sugar alone; for, although the partially fermented wines and malt liquors contain sugar, yet sugar, added to distilled spirit, does not appear to produce the uric acid diathesis. It cannot be the acidity alone, for the wines which are most harmless are quite as acid, or even more so, than malt liquors and the Peninsular wines, and many people, who strongly object to the least acidity in wines, will, nevertheless, often take lemon-juice to an extravagant extent.

If, then, neither the alcohol, nor the sugar, nor the acidity, by itself is the cause of certain beverages proving so injurious, is it a combination of any of these that does the harm? The only conclusion that I can arrive at, with my present knowledge—and it is the result of much thought during many years—is that it is something which is a result of imperfect fermentation, and you will find that it is those beverages in which fermentation has commenced, and has been allowed to proceed to a certain extent and has then been checked, which, of a certainty, cause gout, and, probably, lead also to the production of gravel and calculus. If I am asked to state more exactly what this principle is, I cannot do so; it may be an influence only, a condition of matter, a ferment. At present it is a mystery to me.

In connection with this subject, however, I must return for a moment to that of sugar, which I told you had, as I thought, been regarded askance without due cause.

I would say that I do not, for a moment, classify with sugar either sweetened fruits or vegetables; for I am quite sure that such articles of diet will frequently produce heartburn and other dyspeptic annoyances in individuals who are not in the least inconvenienced by sugar itself. I cannot help thinking that these contain a *something* which is not simple sugar, but a substance which is the result of the long contact of the sugar with the fruit or vegetable juices—a kind of semi-fermented matter; in fact, that same something which exists in the stronger wines and the various malt liquors. Of this I feel confident, that in many cases where sugar, whether by itself, or in tea, coffee, and light puddings, does not disagree, and where fresh fruit, although sweet, produces no discomfort, the combination of sugar with these juices, if time has been given for them to act upon each other, will often cause well-marked dyspeptic symptoms.

But it may be said: If so, a ripe orange cannot be a good thing to eat, as it contains both sugar and acid juice, and these substances have been in contact with each other for a long time. I answer: Not necessarily so; so long as the orange exists as a fruit, with its botanical structure intact, so long there may be no change taking place between the different constituents. We have a striking analogy to this in the case of the bitter almond. When whole, this seed contains the crystalline amygdaline and an albuminous ferment. Separate one of these from the other, and each, by itself, is innocuous; crush and moisten the almond, prussic acid is immediately formed, and the union of the two principles is the production of a deadly poison.

THE SUNDERLAND DISASTER.

By WM. OSBORNE LAMBERT, M.D., L.R.C.P. Lond.

THE following statement by Dr. Lambert in reference to this melancholy accident will be read with interest. It is signed by the four medical men who were engaged in the work of extrication and resuscitation, as evidence of the correctness of the facts and premises:—"My house is situated nearly opposite to the large door on the east side of the Victoria Hall, being the entrance to the area or body of the hall and the gallery. The latter is a very large building, and will seat three or four hundred more people than the Newcastle Town Hall. I have often been sent for professionally to attend upon injured persons during elections and other disturbed occasions, as when the Tichborne riot occurred in the Hall; and quite recently, when Miss O'Gorman, the 'escaped nun,' was lecturing here. The entrances, vestibules, landings, and staircases are as well known to me as my own house. I have always considered that they would be found perplexing should a panic arise, particularly the fatal door. I first heard there was something wrong at the Hall a minute or two before five o'clock. A young lady came to my house and said that a little boy was in a fit or dying at the Hall, and asked if I would go across and attend to him. I hurried across without a moment's delay, and entered the gallery and area door. There were a few people outside. I was told that the little boy was on the steps leading to and near the dress circle vestibule. I found the little fellow was quite dead, and from appearances I came to the conclusion that death had resulted from suffocation. There was no one near the body who could give me any information whatever. A sudden presentiment that a mortal struggle was going on at a certain situation leading from the gallery caused me to run up the flight of stairs, at the top of which is a landing. Turning round a corner in the gallery stairs proper, I beheld the dark horrible pit of destruction, with three hundred or more children in it, and—oh! shocking sight—a heap, most of whom appeared to be dead, so feeble were the groans and cries (for they could not get breath to cry) of the living; hence no one could believe that a few yards from the spot actually more than a hundred were already dead. It may be safely asserted that within five minutes of the block taking place at least this number would be dead. Through the eighteen-inch space that the door was open I could see the hall-keeper making almost superhuman efforts, with others, to release the fatal door, but to no avail. I also saw Mr. Potts's coachman and a gentleman whom I have since learnt was Captain Thomson, late of the s.s. *Nebo*, and others. In the pit and on the stairs to a considerable height, as I have said before, the children were piled up some seven or eight feet. I only saw one or two persons where I was, and they seemed paralysed. The moment I took in the fearful situation I was at the rescue of the living from the dead, as I knew I could save scores more children's lives than by waiting to render professional aid, and that any moment lost meant the loss of many more lives. I was nerving every muscle of my body to the rescue for some minutes, when I found Mr. Waterston, surgeon, by my side, and together we worked with an earnestness that surely never men worked with before. Then more rescuers appeared on the stairs, some of whom quailed before the sight and rushed back with terror. I many times fell down with exhaustion and faintness together with the weight of a body in my arms; I was most thankful when I saw Dr. Beattie making his way down the stairs towards us, knowing him to be a very powerful man, and capable of giving great assistance in an emergency such as this.

Then came the hall-keeper, Captain Thomson, Dr. Bolton, and a strong mason whose name I do not know, and others from the outside of the door who had found their efforts to loosen the door vain. The limited space we had to work in by this time was rapidly becoming blocked. But the work proceeded rapidly, and in about at least thirty-five minutes the last of the dead was lifted from the floor and carried away from the fatal spot. Many of the children on the outer edge of the frightful heap could be made out to be past human aid. They had fallen early in the frightful struggle, and those who came after had been precipitated over them into the far side of the heap. In order to get at the latter, hands had to be joined by the rescuers, so that one might reach over the nearer bodies, and take hold of some little one whose feeble movement gave sign that life was not extinct. These, after being carried up, were then handed over and administered to by the tender hands and feeling hearts of the doctors who had

arrived in large numbers. I am told by the medical men who were acting in their professional capacity beyond the base of the rescuing operations that it was surprising how the children brought up from the pit who had not received internal injuries quickly recovered from almost fatal suffocation, as was evidenced by their showing only a spark of life, such as convulsive movements of the eyeballs and limbs, although insensible, yet after getting into the fresh air they in a few moments would take a drink of cold water most eagerly, and in a very few minutes longer, with very little assistance, would walk away. In comparatively few cases was there any urgent and immediate medical treatment required. On inquiry I only hear of a few cases of broken bones, and these were mostly simple fractures. What seemed to wring the hearts of the rescuers with the utmost anguish were the appeals of those who were able to cry. It was, 'Give me a hand!' 'Oh, do take me out first!' or, 'Oh, where is my mother?' with sobbing, half-choked utterances. We encouraged them to be brave, and assured them we hoped we should soon save them all.

Many of the little children who were at the rear of the crush, finding they could not proceed, turned back, dragging as many as they could with them, and went off through the dress circle vestibule door, which, most fortunately, had been fastened widely open by the hall-keeper before the commencement of the entertainment. After the last body had been removed matches were struck, when the fatal door was found immovable by being bolted into the floor. The hall-keeper asserted, and his assertion is corroborated by statements on the part of boys who passed down the gallery stairs before the general rush began, that this door was open wide a short time before the entertainment closed, but that he found it bolted when he went to ascertain why the exodus had suddenly ceased. Two boys have also stated that a man stationed himself at the door to distribute the prizes to the gallery children as they went out, and that, finding the crowd was coming too fast to allow his doing the work he had been sent to do, the man slipped the bolt so as to fix the door ajar, leaving space for only one child to pass through at a time. All the circumstances of the catastrophe seem to point to this theory as the explanation of the disaster. Many of the rescued children whom I have since seen say they first became unconscious, and remembered no more till after they were extricated. Out of the number rescued very few indeed, proportionally, have since died. Were it not for the early efforts of the rescuing party, I fear that upwards of a hundred more lives would have been lost."

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JUNE 1ST.

The President, ANDREW CLARK, M.D., LL.D., in the Chair.

THE committee appointed to consider Dr. Tyson's case of leprosy presented their report, in which, as a result of microscopic examination of the skin, it was affirmed that bacilli were discovered in profusion.

MR. BARKER ON

A CASE OF LARGE SEBACEOUS OR DERMOID CYST IN THE TONGUE, REMOVED BY OPERATION, WITH CURE.

The case was one of a woman, *æt.* 28, who had first noticed pain and difficulty in swallowing seven years before. Soon after, a swelling was noticed exactly under the tongue in the middle line, and directly behind the *symphysis menti*. This had been increasing ever since. On admission into University College Hospital, it pushed the mucous membrane forwards and upwards, so as to make an interval between the jaw and the root of the tongue of quite an inch broad. It also projected beneath the chin for about an inch and a quarter. The skin over it here was perfectly normal, and in no way attached to the tumour. The whole tongue was thrust much upwards, and its dorsum rested against the hard palate. The tumour was painless, and fluctuated over its whole surface; there was no trace of inflammation anywhere about it. On puncture with a grooved needle, typical sebaceous matter was obtained. On Aug. 12, 1882, Mr. Barker removed the tumour by a

straight incision in the middle line under the chin. The tough cyst was reached above the mylo-hyoid muscle, and lay here, partially separating the genio-hyoidel. It was easily separated from its bed, which lay almost entirely between the genio-hyo-glossi muscles, and reached quite up to the dorsum of the tongue, only covered by the tough mucous membrane of the latter. Blunt instruments and scissors were used, and hardly a trace of blood was lost, no vessels requiring to be secured, except one tiny twig, which was pinched. The wound having been well cleansed with carbolic solution, the skin was brought together with four silver sutures, and the large cavity drained with a tube. The whole thing healed in a few days without any suppuration or reaction, and the patient left hospital on the sixth day after operation. The cyst (*shown*), being removed entire, was found very tough and firm-walled. It measured 3 in. by $1\frac{1}{2}$ in., and was somewhat uniform. Its contents were like porridge, with a faint, sour smell, and under the microscope were seen to be typical sebaceous material. Its wall was fibrous, lined by a thin, glistening membrane, leaving no doubt as to its nature. Mr. Barker then alludes to the rarity of these tumours of the tongue, and in illustrating this fact, states that after careful search he has only been able to collect sixteen recorded cases, exclusive of his own two. From an examination of these, it appears that these cysts may occupy three distinct situations in relation to the tongue:—1. Between the genio-hyo-glossi muscles in the middle line; 2. They may be unilateral—that is, lie between the mylo-hyoid muscle and genio-hyo-glossus of one side; and 3. They may be bilateral, lying above the mylo-hyoid and below the genio-hyo-glossi of both sides. Their contents vary also very much, as also the age of the patients among whom they are met with, although they appear to be, in a sense, congenital. The various modes of treatment are then alluded to, but of all Mr. Barker gives the preference to complete excision without opening the sac, as the easiest and safest operation. This may either be done from the mouth, or by a median incision, as in the last of the author's two cases. The scar left by the last method is very trifling, as seen in the patient exhibited, and the ease and safety of the operation is greatly increased thus where larger cysts have to be removed.

MR. R. J. GODLEE ON CASES OF

STRETCHING THE FACIAL NERVE FOR TIC CONVULSIF.

The first case was the conclusion of one reported in vol. xiv. of the "Transactions" of the Clinical Society, page 44, by Dr. W. Allen Sturge and Mr. Godlee, that of a lady, *æt.* 72, in whom the operation had been performed for right-sided tic. The result had been almost complete relief for nine months, when the spasm recommenced as the result of a sudden and severe nervous shock, and gradually regained all its former intensity. The patient remains in tolerably good health, but still suffers from some neuralgic pain in the face, principally in the right supra-orbital nerve, and at the top of the head, on the left side, at the seat of an old injury. She is unwilling to undergo any further operation. The next case was that of a man, *æt.* 36, who had suffered from bilateral tic for some years without assignable cause. There was no syphilis, and no source of reflex irritation, except some old carious stumps of teeth. It was made worse by exposure to cold and bright light and excitement. He had slight supra-orbital neuralgia on the left side. He was kept under observation for some months, and improved while perfect rest was maintained, but relapsed when allowed to go about. The left supra-orbital nerve was first divided subcutaneously without good effect, and subsequently the left, and afterwards the right, facials were stretched by the same method as in the former case. In both instances the twitching recommenced after three months, as the paralysis disappeared and returned as severely as before the operations. Arguments were adduced in favour of the mischief being situated in the region of the medulla oblongata, and references were made to as many reported cases as the author could discover. It was shown that, though all of these had been reported at first as examples of success, in all (except in one reported by Mr. Southam, of Manchester, which remained quite well after two years) more or less return of the twitching has occurred. Some, however, according to reports carried up to the present time, remain to some extent improved. The total number of cases in the table amounted to thirteen. It was then urged, that if Mr. Southam's case did not exist, we should have to consider this chapter of surgical therapeutics closed, but that while it remains well there is still a certain amount of hope that

the operation may be sometimes successful. It was lastly pointed out that the stretching of a small nerve on a hook acts differently from the stretching of a large nerve with the finger. In the latter class of cases the effect is probably either a loosening of the nerve from its sheath, or some influence on the nervous centre; in the former it causes a solution of continuity of the nerve, but with a certainty of union. The *modus operandi* is, therefore, probably not a profound effect upon the centre, as has been supposed, but merely the breaking of a bad habit, which must be taken for what it is worth.

Mr. PAGE was of opinion that the operation had been more frequently performed than was implied by Mr. Godlee's remarks, and that it was premature to speak of finality in respect to it. He referred to a case operated on by Mr. Pye, and another in which he had himself resorted to the same proceeding for relief of long-standing facial paralysis, in which all other remedies had been tried in vain. The first consequence of the operation was complete paralysis, and, subsequently, return to a condition of slight improvement on the original state. Prof. Braun had recently published observations tending to show that nerve stretching tended to the production of distant lesions.

Dr. ANDREW CLARK observed that Mr. Godlee's paper was an excellent illustration of valuable work. He agreed, however, with Mr. Page that all the cases had not been referred to, and instanced one in which, two years ago, Mr. Hutchinson successfully operated on the facial nerve.

Mr. H. H. CLUTTON on a case of

SPONDYLITIS DEFORMANS.

The patient, who had been exhibited at a previous meeting, was 30 years of age, and the subject of a very severe form of ankylosis of the spinal column. In the family history there was nothing to indicate hereditary taint. In his previous history there was strong evidence of rheumatism affecting the joints. When nine years old he was confined to bed for rheumatism, which, with several intermissions, lasted for six months. It began in the metatarso-phalangeal joint of the right big toe. It then attacked the right knee, and finally the right hip. The latter joint had, he said, remained stiff ever since. Six years ago he had a painful foot, which the doctor called rheumatic gout. He had never had any venereal disease of any kind, and beyond the attacks above described had always had good health. Three years ago he first felt pain and stiffness in his neck, but it had caused him little inconvenience till the last six months. He can give no account of his back or chest, and is not aware that they are fixed and immovable. For the last three months his left shoulder has been stiff and painful, and he still occasionally suffers from rheumatic pains in the right hip. His present condition is one of almost complete ankylosis of the spinal column. He stands with the left leg advanced in front of the right, with the knees bent, and in a stooping posture. His spine presents one large dorsal curve, with the convexity backwards. The head is craned forwards, and the chest sunken and depressed. The movements of the head are very much impaired, although not as yet completely destroyed. He cannot turn his head at all to the right, and only slightly to the left, the nose moving about one and a-half inches from the median line. The lateral movements ordinarily obtainable in the cervical region are entirely absent. In raising and depressing the head, the chin only moves three inches. There is no movement whatever in the lower cervical vertebrae. This is very apparent on trying to make the patient bring his chin towards the sternum. On bending the whole body forwards, it is seen that the spinal column is quite rigid; there is no separation between the spinous process, or increase of curva. With the knees extended, the tips of the index fingers just touch the patella, and this movement appears to be effected by the hip-joints. The respiratory movements are entirely abdominal. On the deepest inspiration there may be some slight expansion, but there is no elevation of the ribs. His height is now 5ft. 2in. in his boots, and he is quite sure that some years ago he was 5ft. 5½in. when measured in his boots against the wall. As to other osteo-arthritic changes, the patient has several creaking joints and distinct "lip-growths" in both shoulders and big-toe joints. He has also distinct limitation of movement in the left shoulder. The right great trochanter is larger than the left, and tender on pressure. All the other joints except those named seem perfectly healthy. Such an extensive and severe form of ankylosis of the spine, with or without osteo-arthritic changes elsewhere in the body, is a rare condition in

a man 30 years of age, and it was on this account Mr. Clutton brought him before the Society. A similar case was shown at this Society by Dr. Allen Sturge, and is recorded in the Clinical Society's "Transactions," vol. xii.

Dr. LEDIARD on a case of

SPONDYLITIS DEFORMANS AND OSTEITIS DEFORMANS.

The patient was a miner, *æt.* 58, from Cumberland, who had suffered from repeated attacks of pain in the spine, and rheumatic affection of the joints, and of late years stiffness of the spine and head, so that the body was bent forwards in a stooping posture. The spine was absolutely ankylosed except for slight movement in the neck, and the head was firmly fixed to the spine. Several joints presented chronic rheumatoid arthritic changes; there was no movement of the chest walls, respiration being entirely diaphragmatic. The femora were curved forwards and outwards, and the shafts, somewhat massive, suggesting the disease known as osteitis deformans in possibly an early stage. The skull and clavicle were, however, unaltered.

Dr. DYCE DUCKWORTH said it was difficult to account for the rarity of the disease if it was due to rheumatic arthritis. Mr. Hutchinson put the origin of many such cases in gonorrhoeal attacks, but he was uncertain if this experience was borne out by that of other surgeons. It was fortunate the disease was so rare, since it was so hopeless of cure.

Mr. CLUTTON said that, in spite of particular inquiry as to the occurrence of gonorrhoea in his patient, no proof of this had been obtainable.

Mr. GEORGE LAWSON related the history of

TWO CASES OF EPITHELIOMA WHICH HAD OCCURRED ON OLD CICATRICES, AND WHICH HE HAD REMOVED.

In the first case, the patient, a pale, anæmic woman, *æt.* 38, had lost, in childhood, the sight of both eyes, except the bare perception of light, from an ulcerative inflammation, probably diphtheritic, and which had caused complete adhesion of the upper and lower eyelids of each eye to the globe. The patient was admitted into the Middlesex Hospital in May, 1881, and the growth first commenced in the previous September. It sprang from the cicatricial tissue which united the left lower eyelid to the globe, and steadily increased until it obtained the dimensions shown in the drawing, the whole front of the eye being occupied by it. Mr. Lawson removed the growth and the eye. Two years has now elapsed since the operation was performed, and there has been no recurrence. In the second case, the patient, a strongly-built man, *æt.* 30, was admitted into the Middlesex Hospital in March, 1881, with an epithelioma of the left thigh, which occupied the greater part of a large cicatrix. Twenty years previously his left thigh was crushed by a heavy cart passing over it, which caused great laceration of the skin and muscles. He was seven months in the Aylesbury Hospital, and when he was discharged there was still an unhealed superficial wound of about the size of a small saucer. He then went to work as a farm labourer, but the wound never healed. Two years and a-half before his admission into the Middlesex the wound took on a new action. It began to spread rapidly, the granulations became large and fungoid, and it occasionally bled. On admission, there was found an epitheliomatous ulcer measuring seven and a-half inches by eight inches. Mr. Lawson amputated the thigh just below the trochanters, and although two years have elapsed, there has been no recurrence of the disease. Mr. Lawson remarked that the cicatrices which seemed specially prone to epithelioma were the tight cicatrices such as are caused by a great destruction of skin, and those cicatrices upon which there is a constant tension. Both the cases, he said, tended to show that if epithelioma can be completely excised before it has affected lymphatic glands, it is the form of cancer which is the most amenable to treatment; whilst experience has taught us that after the lymphatic glands are invaded, epithelioma is the most formidable and irremediable of all the cancers.

Mr. GODLEE asked whether the epithelioma arose in the centre or at the circumference of the cicatrix.

Mr. LAWSON said that in his own case it arose at the margin of the scar.

Mr. WARRINGTON HAWARD observed that the cases described pointed to the conclusion that in such forms the disease was purely local; and he cited a case in which the region of a large burn was for twelve years subsequently the site of a granulating sore. Then active fungation set in, and much pain was experienced. Skin grafting was tried without result,

and amputation of the leg—which was the part affected—was performed, an epitheliomatous structure being clearly seen in it. There was no history of cancer in the patient's family for some generations before, and now, seven or eight years later, she continued in good health, having had no recurrence of the growth. Other examples could be quoted of long unhealed sores resulting in cancer, and they taught that immediate removal of such parts should be adopted.

Mr. BARKER also regarded the cases as affording striking proof of cancer originating from local irritation.

Mr. PEARCE GOULD mentioned two cases treated in the Westminster Hospital, one, that of a woman in whom cancer spread from the edge of a scar on the thigh; and the other, of a man who had been shot in the leg eleven years previously, and in which case epithelioma spread round small sinuses communicating with shot remaining in the tibia. The resemblance of such less malignant forms of cancer to rodent ulcer was insisted on by Mr. Pearce Gould.

Dr. ANDREW CLARK inquired whether Mr. Lawson had found cancer originate in syphilitic cracks in the tongue.

Mr. LAWSON replied that syphilitic tongues were more commonly cancerous than non-syphilitic. He regarded irritation as a common cause of cancer, and thought that the epitheliomatous growths under consideration might be managed in their early stages, but were intractable later. In operating, however, the whole of the affected tissue must be removed.

Dr. RADCLIFFE CROCKER read the case of a girl, *et. 12*, with
NODS FROM CONGENITAL SYPHILIS.

The patient had been shown at a previous meeting. She had enteric fever five months before she came under notice, and during convalescence, two nodes appeared on the forehead, one on each side of the median line; there was another tumour in the right orbit, softer than the nodes and movable. There was no corroborative evidence about the girl except the two upper central incisors, both of which were notched, and one was slightly pegged. No history of infantile syphilis could be obtained, and the mother and the other children were apparently quite healthy; but eventually it was ascertained that the patient was a child by a previous husband, who died soon after their marriage, had lived a dissipated life, and was never well, but resented inquiries into the cause of his ill-health. The patient was put under iodide of potassium, and when last seen the softer tumour had quite gone, and both the nodes were softer and much smaller, and the improvement in the general health of the patient was very striking. Dr. Crocker remarked that the case corroborated Sir James Paget's observation that typhoid fever often aided as the discoverer of constitutional taint, and also Mr. Hutchinson's observations on the value of the notched and pegged incisor teeth as evidence of congenital syphilis.

Dr. FREDRICK TAYLOR on a case of
INFANTILE HEMIPLEGIA WITH UNUSUAL REFLEX PHENOMENA.

The patient was a child, *et. 5*, who was taken with convulsions at twelve months old. These lasted two hours, and were followed by weakness of all the extremities. In a few days the right arm began to move, and the right leg, but the left limbs remained paralysed. Gradually rigidity developed, and with it the curious reflex irritability to be described. The child was fat and well, commonly semi-recumbent, with both legs semi-flexed and rigid, the left arm flexed at all joints and rigid. This arm is scarcely used, but the right freely and well. Both legs can be moved, but not completely flexed or extended. The right is less rigid than the left. The child cannot sit up in bed, nor stand upright, nor walk. The left arm and leg are nearly two inches shorter than the right arm and leg respectively. On making a sudden noise near the patient the left arm is quickly thrown out at right angles to the body, the elbow, wrist, and fingers are extended, the face assumes a puzzled expression, and the legs undergo moderate extension. The condition of spasm remains for about thirty seconds, then slowly relaxes. The same reflex contractions are brought about by shocks affecting the surface of the body, a blow on his crib, a tap on the head. Vision appears to be good, but he has disseminated choroiditis in very small patches in both eyes. He is lively, fairly intelligent, and can talk. He passes feces and urine involuntarily. But for the choroiditis there is no conclusive evidence of congenital syphilis. He has been four months treated with iodide of potassium and mercury, but shows no material improvement. Dr. Taylor thought the case was allied to those of infantile hemiplegia with spastic or choreic phenomena occurring

afterwards. Though not strictly unilateral, the disease on the left side was obviously of cerebral origin, and that on the right side must be explained by a second lesion, or more likely by a single lesion crossing the middle line. The mode of origin suggested obstruction of a vessel, with syphilis as a possible antecedent. Its early occurrence and the deficient growth of the left limbs rendered it probable that asymmetry of the brain also co-existed.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

A METHOD OF RENDERING THE SKIN INSENSIBLE IN OPERATIONS WITHOUT CHLOROFORM.—M. Jules Guérin read a note at the Académie des Sciences upon a method of rendering the skin insensible in those operations which do not admit of chloroform by inhalation, and cited a case in which he had employed it to advantage. A lady, *et. 60*, consulted him three months ago for a tumour in the right breast of eight years' standing, which, on examination, proved to be a scirrhus. The general health was bad, bronchial and cardiac troubles were very manifest, and the kidneys were not in a very satisfactory condition. However, the operation was urgent. Chloroform having been considered dangerous, M. Guérin applied around the tumour a circular layer of Vienna paste, limited by a double band of diachylon. At the end of twenty minutes the caustic was removed, leaving in its trace a black ribbon-like line. The knife was then applied, and the tumour removed without the patient feeling the slightest pain, and who did not seem to be aware of the operation. The results were all that could be desired.

ANKYLOGLOSSIS.—At the meeting of the Société de Chirurgie a member invited the opinion of his colleagues in a case of ankyloglossis which had come under his notice. The patient was an infant, two months old, and from the peculiar position of the tongue, which was totally adherent to the floor of the mouth, the child was unable to suck, and consequently was rapidly wasting away. He thought that an attempt might be made to disengage the tongue by the thermo-cautery, but waited the opinion of his colleagues. M. Champonnière said he had seen a child presenting a deformity analogous to this case. The tongue was fixed to the floor of the mouth in its whole length. With the scissors he was able to set free the point, and the child was able to perform suction satisfactorily. He did not see why a similar operation should not be tried in the case under consideration. M. Verneuil could not believe that such a simple operation would be attended with a sufficiently satisfactory result in this case, although it might suffice where the deformity was not so complete. M. Trélat had occasion to observe a case of ankyloglossis in which the tongue was attached to the floor of the mouth by two fimbriated mucous folds, one on each side. A cut with the scissors sufficed to set free the organ. He might suggest that it was possible that a similar disposition of the parts might be found in the case of his *confrère*. M. Sée observed that, if the tongue was simply separated from its adherences a relapse was sure to occur. It would be necessary in consequence to interpose between the two surfaces a piece of mucous membrane which might be taken from the cheek. M. Tillaux was of opinion that nothing should be done, as an operation on a child two months old, weak and sickly, could not be followed by any good results; it was better to let a child die quietly than to kill it. After some other remarks from different

members, the subject dropped, but not before the member, who had charge of the case, expressed his determination to hazard some kind of operation.

BRIGHT'S DISEASE.—At the Académie de Médecine M. Seminola, of Naples, explained his theory on Bright's disease. According to him, the alterations observed in the renal tissue are not the cause, but the result, of the infiltration of albumen. The albumen is altered in its quantity and composition. Its characters in the serum of the blood are not normal, and consequently it must be eliminated from the economy. M. Seminola injected by little quantities under the skin of healthy animals albumen of different kinds. After some time the kidneys became affected in a similar manner as that observed in Bright's disease. This new theory was tacitly received by the meeting, and immediately afterwards a discussion on the report of the Typhoid Fever Commission was commenced. This Commission was formed to furnish the authorities with advice on the best prophylactic means to be adopted against that affection.

A FURIOUS ANTI-VIVISECTIONIST.—M. Brown-Séguard was interrupted rather brusquely the other day in one of his courses of experimental physiology at the College de France. A monkey was brought on the table and the learned physiologist commenced his lecture by explaining the nature of the experiment about to be made on the animal. The monkey seemed evidently well-pleased by the observations, for he highly amused the whole audience by his mimics. But when the lecturer went to seize him he cried most piteously, as if he had a presentiment of what was in store for him. Having thrown him on his back and bound him, M. Séguard took the scalpel and, was in the act of plunging it into the animal, when, to his great surprise it was adroitly sent whirling across the room by a straight tip from the umbrella of an indignant lady member of the Anti-Vivisection Society. The humiliation of the lecturer can be easily imagined, however, recovering his *sang froid* he requested his assailant to leave the Hall, but was met with a stern refusal from the lady, who said that, as she had no other way to show her disgust for such practices, she had determined to prevent them by the means she had chosen. However, the influence of an *agent de paix* was brought to bear on this member of the gentle sex and she left, protesting all the way. The scalpel was picked up, and now that his defender was gone poor monkey had to submit *bon gré mal gré* to the operation in question, and the lecture was finished without further interruption.

RESECTION OF THE LUNG.—Your correspondent is always glad to be corrected when he inadvertently makes a mistake, either as to the name of authorities or the subject of facts. But at the same time he is generally surprised when one of those rare occurrences take place, as he is always very careful as to the selection of his sources of authority. In any case, although it is quite possible that the credit of such an operation is not to be attributed to Koch of Berlin, but another Koch, the fault is not to be laid at the door of your French correspondent, but at that of the *Bulletin de Thérapeutique*, a journal always well-informed and edited by several of the best lights of the metropolis. The article commences thus, "Koch de Berlin très connu dans le monde scientifique pour ses recherches sur le bacillus de la tuberculose vient de tenter une operation, &c. I would advise "the writer of the summary" to exact without delay a correction in the journal referred to, as it seems of such importance to him. There is no doubt he will get every satisfaction.

MEDICAL ACTS AMENDMENT BILL.

A STATEMENT of their case has just been issued by the Royal College of Surgeons in Ireland which embodies, as we think, most of the points which can be urged by the Irish licensing bodies, and is, therefore, worthy of special notice.

With reference to the constitution of the Irish medical Board the College proposes that the Irish Medical Board shall consist of thirteen members, *i.e.*, twelve from the licensing authorities which are recognised by the Bill, together with the direct representative for Ireland; and it submits that the Colleges of Physicians and Surgeons should not have a smaller combined representation on the board than the Universities, because (a) the medico-educational work done by them is much greater, and (b) the medical examination standard, as evidenced by the percentages of rejections, is not, in any respect, lower than in the case of the Universities.

As regards the standard of general education required for their admission to the profession, the College recognises the claims of Graduates in Arts, or of Under-graduates in Arts, of three years' standing, to a special exemption from examination fee, but it does not admit that other University students are entitled to any special consideration, or that bodies which grant qualifications to candidates of lower Arts standing than three years have any claim to predominant influence in the Medical Board.

The College submits that the representation of the Irish licensing bodies in the medical board which it urges is consistent with the principle upon which such representation has been fixed in the other divisions of the Kingdom. In England the licensing of the great majority of practitioners is effected by the Colleges of Surgeons and Physicians, and, therefore, a large predominance of representation in the Medical Board is given to these two bodies, which return as many delegates as the five universities combined, the result being an equally balanced influence between the universities and the colleges. In Scotland, on the other hand, the greatest proportion of medico-educational work is done by the universities, which are, therefore, given a predominant representation of 8 to 3.

Admission of the Direct Representative to the Medical Board.

The College is of opinion that the Bill will not be acceptable if the direct representative be excluded from a seat at the Medical Board of his own division of the Kingdom. One of the chief purposes of the reconstitution of the Medical Council was to give the profession at large an influence in education and examination; but the Bill does not fully effect this object, for it limits the direct representative to the occupation of a seat for a few days annually in the Medical Council, with a vote as one of eighteen members, in the exercise of the supervisory powers of that Council. The direct representative for Ireland, for example, would have no direct voice in the arrangements for preliminary or professional education—the appointment of examiners—the regulation of fees for study or for examinations—the recognition of examining bodies in Ireland, or any of the other functions of the Board. These important matters would, in the absence from the Medical Board of the Crown nominee and the direct representative, be ruled exclusively by the delegates from licensing bodies, an arrangement which the Bill is expressly intended to prevent.

Uniformity of Educational Standard throughout the Kingdom.

The College strongly urges that it shall be impossible for the Medical Board of any one division of the Kingdom to accept a shorter and cheaper course of medical study for its examinations than that required by another board. The chief purpose of the Bill is to ensure competency of the practitioner, by requiring a sufficient minimum of education, and to put a stop to the practice of students who are not educated up to the requirements of their own country,

resorting to institutions of a lower educational standard elsewhere. The Bill attempts to meet this downward competition between Medical Boards by providing for uniformity of examination, but it permits any amount of downward competition in curriculum of study.

This lowering of the extent of courses of study and consequent cheapening of education has, in fact, caused a migration of a very large number of Irish students from their place of education to seek qualifications from licensing bodies elsewhere which accept a lower, briefer, and cheaper curriculum; proof of this statement can be found in the evidence given before the Royal Commission.

This College does not desire to limit schools as to their method of teaching, so long as that teaching is *bona fide*, and it is entirely willing that the course of study shall be fixed as the Medical Council deems expedient; but urges that whatever studies be considered indispensable they would be imposed strictly upon the students of every division of the Kingdom without exception.

Education and Examination Schemes to be made by Medical Council.

The College is strongly of opinion that the subjects and extent of final examinations, and of the required courses of study, should be fixed by the Medical Council, and not by the local Medical Boards. As the Bill now stands, each Board would make, in all probability, its own scheme of a totally different scope and character from those of the Board, and the Medical Council would be obliged to bring these schemes into uniformity against the opinion of the Boards, and, probably, in face of frequent appeals to the Privy Council—a system which would obviously increase enormously the labour and cost of making a general scheme.

Allocation of Surplus Funds.

Under the Bill two sorts of funds are contemplated—*a*. Three local Medical Board Funds, resulting from the surplus of the fees paid to local Boards for final examination, over the expenses of same; *b*. A Medical Council Fund, resulting from the assets from the three existing Branch Councils, plus the fees of £5 each for registering practitioners.

Fund *a*. (the Local Fund) is applicable, *inter alia*, after payment of expenses, to maintenance of "medical museums and medical libraries belonging to a medical authority." Fund *b*. (the General Fund) is applicable "for the benefit of the medical profession, or in such manner as the Medical Council may, with the consent of the Privy Council, determine."

The College solicits attention to the operation of these arrangements in Ireland. Fund *a*. would probably be insignificant in amount, because University undergraduates would be exempted from contributing to it, and the entire expenses of maintenance of the local Board and payment of examiners would constitute a first charge on it, therefore the surplus available for maintenance of Irish "museums and libraries" would probably be very small.

Fund *b*. (the General Fund) would, on the contrary, be large. It would start with the aggregate capital of the three existing Branch Councils (£29,000 + £2,000 + £1,869), amounting to £32,869, and yielding an interest income of nearly £2,000 a year. It would have also an income of almost £6,000 arising from registration of practitioners; and against this total income of £8,000 it would expend for the Medical Council and its establishment about £3,500, leaving a yearly profit of about £4,500 available for any purposes within the wide area of the phrase quoted above.

The College submits that the maintenance of great Irish educational institutions ought not to be left either to the insignificant local Fund or to the unlimited discretion of the Medical Council, of whom only four members will specially represent Ireland, and it proposes that the Medical Council Fund shall be allocated to each division of the Kingdom proportionately to the medico-educational work done therein, and shall be there distributed by the local Medical Board. It appears, taking the three

years last passed, an average of 2,048 new students were registered each year throughout the Kingdom, of whom England supplied 966 annually; Scotland, 580; Ireland, 502; total, 2,048. Calculating on this basis and dividing the gross central surplus fund into hundredths, it appears that, in respect of its medical educational work, the English Divisional Board should receive 47·1 per cent. of the entire fund, Scotland 28·3, and Ireland 24·5.

Exemption of University Undergraduates from Examination Fee.

Clause 36, page 22, lines 19 *et seq.* declares that "the fees (for final examination) to be paid by University graduates or undergraduates holding University certificates of having passed the examinations at their University . . . shall not exceed the portion of the fee leviable . . . for the administrative expenses of the Board." The College is willing to accede to this concession to full Arts graduates of Universities or to undergraduates of at least three years' standing in Arts; but it altogether dissents from the proposition to extend such privilege to students who are only University undergraduates in name, and who have not acquired a claim—by *bona-fide* academic studies—to the enjoyment of such privileges. The College draws a marked distinction between Universities such as Oxford, Cambridge, and Dublin, which accept no candidate for their medical degrees but those who have fulfilled a complete curriculum in Arts as well as in Medicine, and those other Universities which grant their highest medical degrees to students who are little more than matriculants, who pass but one, or, at most, two preliminary examinations of no higher standard than the analogous examinations of the College,—who are examined, but not, in any respect, educated in these Universities,—who do not reside therein, and who are not called upon to pay the cost of complete Arts studies. Such Universities, being simply examination centres, have even less claim to special privileges than this College, which both educates and examines and maintains for purely public purposes an educational establishment of the greatest value, without calling upon the public purse for any assistance.

Affiliation of Examiners to a Licensing Body.

The Bill confers on the examinee of the local medical board a right to be registered and to practise, but it does not give him a title by which his *status* shall be indicated. The College is of opinion that an examinee who has passed his primary examinations at a College or University, and his final examination before a medical board should be affiliated by the College or University *ipso facto* without additional examination, and upon a small fee (if any). But it would be an abuse of the system if such students should go off to another licensing body and obtain its diploma without having been associated with it during studentship, or having passed any examinations therein.

Signed, as delegates for the Royal College of Surgeons in Ireland,

WILLIAM IRELAND WHEELER, President.
RAWDON MACNAMARA, Representative on
General Medical Council.
JAMES KELLOCK BARTON, Past President
and Councillor.
ARCHIBALD HAMILTON JACOB, Councillor.

THE MEDICAL BILL.

THE position of the Bill as one of the secondary measures of the Government is becoming every day a subject of greater anxiety to reformers, for, though Ministers are evidently determined in passing it, if at all possible, yet the embarrassments of Government legislation are just now so great that an organised opposition would certainly be fatal to the measure this session.

We understand that the Government will probably devote Saturdays to this and other secondary Bills, including a London Police Bill (which is considered of first importance), the Union Officers' (Ireland) Superannuation Bill, and other class legislation which still hangs fire. On these Saturdays the rule that opposed measures shall not be taken after midnight cannot be availed of to stop progress, because the House sits at noon and goes on without limit, and ample time is thus afforded to take opposed Bills before midnight.

Nevertheless an organised opposition could interpose insuperable difficulties, and it is for this reason especially that we regret to observe that Mr. Mundella has evinced a disposition to refuse consideration even to reasonable amendments, which, being consistent with the principles of the measure, might be conceded to the licensing bodies which put them forward. In this respect we think

that the attitude of the Minister, as well as the policy adopted by certain representatives of medical reform, is extremely unwise.

These advocates of reform think that they most effectually support the Bill by declaring their readiness to swallow it entire without particular inquiry as to its ingredients. They represent the profession as being so hungry for direct representation that it will thankfully accept any Bill which contains that concession, and without waiting to inquire whether the measure is in other respects acceptable, or whether it really provides for the one point which they consider essential. By reiterated begging for this boon they have, we fear, succeeded in persuading Mr. Mundella that, so long as he grants it, he need not trouble himself with the other details of the Bill, and they have thus caused him to assume an attitude toward remonstrants which is, we think, in the last degree undiplomatic.

These representatives of reform of whom we speak seem entirely to forget that, if they abstain from seeking to improve the Bill, their doing so will not in any material degree relieve the Government from the pressure of amendments promoted by other parties, and Mr. Mundella would be wise to recollect that these amendments cannot be met with flat refusal, unless the Government is prepared to make the Bill a Cabinet measure of the first order, and force it through by the votes of the Government majority.

We feel that it is not reasonable for the Government to meet suggestions for improvement with the declaration that reformers must take the Bill as it stands, or no Bill, and we must say that, putting out of consideration the very influential class in the profession who are hostile to reform, and would be delighted that the Minister would carry out his threat to abandon the measure, there is also a large section of reformers who would almost prefer to wait and agitate for another year or two rather than accept for the next twenty years a defectively reconstructed system.

We would, therefore, earnestly advocate a change of policy before it is too late. The Bill will probably not be seriously opposed on second reading if the licensing bodies have reason to hope that they will have fair play when the Bill goes into committee; and, therefore, with a view to smooth the way for further progress, we think that the advocates of reform ought to help the Government by suggesting concessions, and that Mr. Mundella ought to consider the suggestions in a compliant spirit so long as they are neither impracticable nor inconsistent with principle.

We warmly support the Government in refusing to sacrifice principle or important detail to the individual interest of any licensing body, but we cannot approve of a determination to hear no remonstrance or make no concession; nor can we listen to a repetition of the formula that if the profession does not like everything the Bill contains it will get nothing else.

THE RECENT ANTI-VACCINATION COLLAPSE.

NOTHING that has occurred within recent times has more conclusively demonstrated the arrogant pretensions of anti-vaccinators than the debate and its result

we have nothing but admiration ; although it must be added that the sections wherein the relations of the Council itself towards those guilty of fraudulent practices connected with unqualified practice, are dealt with, reflect the besetting weakness of the Council as a judicial body, and rightly enough have provoked a crushing and unanswerable retort from Dr. Ogle.

It was to be expected, as a matter of course, that objectors to the Council's proposals for preventing a continuance of unqualified practice would arise ; but we must confess to a feeling of real concern at the attitude assumed by our contemporary, the *British Medical Journal*, towards a reform that is as necessary as it is just. The whole weight of evidence is abundantly favourable to the main argument of Dr. Chambers' report, that, namely, the interests of the public and of the profession alike demand that every responsible medical practitioner shall be legally *qualified* to assume charge of the sick. So long as this primary truth is evaded, the whole matter in dispute is shelved ; and with it go also the principal factors that strengthen the hands of innovators pledged to remove existing abuses. It is no part of the duty of conscientious workers in the path of improvement to take into consideration what hardships will be suffered by men who are enjoying the fruits of unjustifiable practice when they are surrounded by disabilities of a penal nature, for the whole success of their lives has been obtained at the expense of risk to the public welfare. Indeed, so glaring are many of the abuses brought to light by recent inquiries—abuses inseparably associated with the employment of unqualified assistants—that excuses might be forthcoming for much more drastic proceedings than are proposed in Dr. Chambers' report ; and even in the utterances of apologists for the system which have appeared since the issue of the official document, it is not difficult to discover substantial reasons for speedy and effectual dealing with the problem in hand. The plea of expediency is naturally enough the principal one put forward in defence of giving to unqualified men the position that should never be occupied by them ; and the most frequently urged complaint against reformers is that they will, if they persist and succeed in their endeavours, be depriving the poor of a valuable and indispensable means of relief. This objection is plausible because it has a philanthropic ring ; but it is devoid of all foundation in fact. The services, cheaply purchased though they are, of the majority of unqualified assistants are in the end effective of little saving to the employer. It is true that he may, by a dereliction of duty, leave to his assistant the performance of tasks that can only be illegally fulfilled by such a representative, and he may thus conduce to his own more comfortable existence by prostituting his conscience and his honour ; but even the most diligent and successful unqualified assistant, sooner or later, plunges into error, in the consequences of which his principal is dragged no less than himself, and with results that not infrequently prove permanently injurious in a professional respect.

We are less concerned, however, to analyse the objections to reform at present, inasmuch as the voice of all those to whom the dignity and honour of their

calling are higher considerations than pecuniary advantage is unanimous in demanding such changes as will remove the reproach under which medicine suffers so long as its qualified followers lend their help in promoting the scandal of unqualified practice. Nothing could indicate more clearly the growth of opinion on this subject than the evidence of those who are quoted by Dr. Chambers as having replaced unqualified men by duly qualified assistants, with advantages they do not hesitate to acknowledge. It should be remembered, moreover, that sharp and sudden transition from the existing state of things to that under which unqualified assistants will no longer be permitted to exercise responsibility is deprecated by Dr. Chambers, and is not sought by even his most enthusiastic supporters. Sufficient time will be afforded for the accomplishment of necessary changes quietly and without undue interference with personal rights and privileges ; and under the new *régime* as much liberty as they now enjoy will still remain to medical men to be assisted, ministerially, by students who are, *bond fide, in statu pupillari*. Without entering into the merits of etymological quibbles, on which some partisans of unqualified assistants have striven to raise discussion, it may be at once admitted that the employment of assistants had its origin at a time when pupilage to a practitioner formed the sole means of medical education ; such a mode of obtaining help was both legitimate and useful, and aid so secured was confined within purely *ministerial* limits ; it did not, as it could not by any stretch of right, include performance of responsible functions, but only of duties which were discharged under the eye and direction of the *master*. It is a refinement of objection to urge that extension of this principle to that involving full responsibility on the part of *experienced* assistants is permissible and reasonable. It is *not*. For one thing, such an extension is illegal ; it ignores the privileges of qualification, and it at once places the man who has honourably pursued the curriculum and passed the examinations prescribed by law on a level of equality with the competitor who, either through incompetence or negligence, has failed to raise himself to the position of a qualified practitioner. Those, too, who employ such unqualified men are guilty of the offence which the latter themselves commit against registered practitioners ; and the mere question of moral right has, when properly appreciated, so strongly appealed to the senses of some employers of unqualified men that it has influenced them to cease pursuing an objectionable practice.

It would be premature to speculate just now on the probabilities of the suggestions made in the report being carried to fulfilment ; and it may probably be for the best if any immediate legislation is not the result of it. It is infinitely to be preferred that amendment should come from within the profession, of its own volition, and as the practical outcome of a general feeling condemnatory of the evils attendant on a most vicious system. Such improvement may possibly be of slow growth, but it is not difficult to perceive the germs of it already expanding ; and as it increases it will naturally react on larger and larger circles to the extinction of the reproach.

In the limits of an article like this we have been unable to discuss in detail the numerous points raised in Dr. Chambers' report; but this is the less necessary, since, as stated above, the report is mainly in agreement with our own utterances; and we may be content with directing attention to, and advocating, the suggestions for change and improvement contained in the report, while fully agreeing also with the most stringent recommendations formulated in the document.

THE IRISH LUNATIC POOR BILL.

LORD CARLINGFORD has, within the past week, presented to the Lords a most important Bill, to provide for the maintenance of harmless lunatics in Ireland, and also to reconstruct the Irish Lunacy Department. The first part of the measure is practically identical with the Bill which was introduced by Mr. Litton, Q.C., in 1880, and which was of necessity dropped by him when he accepted the Commissionership of the Land Court. The same measure was, in the next session, taken in hand by Lord O'Hagan, and for the second time it was abandoned when his Lordship resigned the Chancellorship. For the third time the Bill appears now as a Government measure, and we trust that this time it will pass, if, indeed, the block of business in the Lower House will permit of its being got through its stages there.

There is, strange to say, no method at present provided for the certifying of harmless pauper lunatics in Ireland. The dispensary medical officer may be served with a ticket to visit such a patient, and must attend and prescribe, but it is not a part of his duty to certify anything unless he is retained and paid as a private practitioner by the patient's relatives, and even then the process of getting such patient into an asylum is so complex that any easier method of disposal is preferred. That method is found in the Dangerous Lunatics Act, which enables a magistrate to commit to an asylum a lunatic who is apprehended by the police as dangerous, and under this Act it is customary to regard all sorts of lunatics as dangerous, and to treat them accordingly.

Lord Carlingford's Bill is simply an extension of certain parts of the English lunacy law to Ireland. Under its provisions a constable or relieving officer "who has knowledge that . . . any person is deemed to be a lunatic, and that such person is . . . not under proper care or control, or is cruelly treated or neglected . . . shall give information to a magistrate," who may, thereupon, either visit the patient or direct the nearest dispensary medical officer to do so, and to report in writing, and if he be satisfied of the truth of the information, the magistrate may cause the lunatic to be brought before two magistrates, who, on further examination and a further medical report, may, if they are satisfied that "his lunacy is chronic, and that he is harmless," remit him to the nearest workhouse, or may place him in the custody of some relative who will take care of him.

For examination and certifying of lunatics each medical officer is to receive a fee such as the justices order, not exceeding £1, or, for both the preliminary and subsequent proceedings, £1 10s., to be paid by the guardians, and any relative of the lunatic who would be chargeable for his relief in workhouse is to pay for his maintenance.

Those lunatics who are boarded out of the workhouse, or with relatives, are to be visited and reported on twice a year by the local dispensary doctor, who is to receive 5s. for each such visit.

The third part of the Bill provides for the reorganisation of the Central Lunacy Department. The office now existing in Dublin Castle is to be merged in the Local Government Board for Ireland, and the two inspectors, Drs. Nugent and Hatchell, to cease to hold office. Two new inspectors are to be appointed under the Board, "being physicians or surgeons of seven years' standing, to assist in carrying out" the new system, but either of the existing inspectors of lunacy may be drafted into charge of the department under the Local Government Board.

It will be seen that this is a measure of the highest importance, and requiring more consideration of detail than we can give to it at the present moment. On a first inspection, and after full consideration of the former Bills on which it is based, and of the fact that the system has had ample trial in England, and been found to work well, we feel able to give its proposal our unqualified approval. Its provisions for the custody of harmless lunatics are much needed, and they will enable a large part of the lunatic population to be provided for in workhouses at a cost which will be only a fraction of their expense of maintenance in district asylums. The departmental part of the Bill is also much needed, and we think it a wise proposal that the pauper lunacy administration of Ireland shall be placed under the same control as the other arrangements for the relief of the poor.

We trust that in the selection of inspectors by the Board the principle of promotion from the ranks of the department will not be forgotten, and that we shall not see outsiders with political influence placed over the heads of competent and experienced Poor-law officers.

SCOTCH INTERESTS AND THE NEW MEDICAL BILL.

At the important meeting referred to in another column, representatives of the University of Glasgow were present in the persons of Drs. Leishman and Young, and the former of these gentlemen, in a speech conspicuous for moderation and gentlemanly good taste, said the best that could be said, and in the best possible manner, for the Universities of Scotland, a fact on which, considering recent exhibitions, the University of Glasgow is to be congratulated. So great is our respect for Dr. Leishman's excellent address, and so conscious are we of the deserved weight which it will carry, that we cannot allow it to pass without indicating its salient features and the manner in which his arguments have been answered by Dr. MacVail. Dr. Leishman does not deny that at present the Universities possess a monopoly, but he contends, in opposition to the document issued by this meeting, which he describes as "fantastic in its extravagance," that no new monopoly was created by the Bill, nor could he see that there was freedom in any sense at present enjoyed by the extra-mural teachers of which it was in contemplation to deprive them. Now it will be admitted by most people as an ultimate fact that the nature of the monopoly at present enjoyed by the Universities is the *extent to which*

teachers are examiners. So long as teachers continue to be examiners, and to the extent that they are so, to that degree is there an unfair advantage accorded to them in competitive teaching, as students will naturally gravitate, no matter what the relative differences of merit as teachers, towards those who are to examine them for their qualifications. Certain obvious results flow from this. In the first place, medical reform, to make any pretensions to completeness, must recognise the fact that the teaching and the qualifying functions be completely severed. Medical reform will, therefore, be incomplete to the extent that they are *not* severed. Now at present in Scotland it is possible for a student to receive a complete course of medical education, and a legal qualification or qualifications from one of the Corporations, without going near a University, whereas, as it at present stands, the new Bill provides that the new Medical Board for Scotland will consist of *eight* University and *only three* Corporation members. It is thus undeniable, in opposition to the view of Dr. Leishman, that if no new monopoly is created the present one is mischievously strengthened at the expense of the Scotch Corporations. That this provision, if it become law, will be unfair to the extra-mural teachers, and prejudicially affect the extra-mural schools, does not require to be insisted upon.

Dr. Leishman further contended that the disparity of the present numbers on the Divisional Board, if carefully looked into, disappears, seeing that the University of St. Andrews, being more of an examining than a teaching body, its vote would be invariably given in favour of the Corporations, and the numbers would thus become, not eight to three, but seven to four. There is a tacit acknowledgment in this contention that all voting in the Divisional Board will be determined by interest, and on this point all that requires to be said is that any board influenced by any interest whatever in passing men into the profession is unwholesome, and can never command public or professional confidence. If the Universities must necessarily give seven votes in favour of their pecuniary interests, and the Corporations, in like manner, give four, the University preponderance would surely continue strong enough.

In answer to the charge that the Scotch Universities were consulted as to the relative numbers on the Divisional Board, Dr. Leishman frankly says: "No one connected with the Scotch Universities knew, until the Bill was issued, what the numbers of these Divisional Boards were to be, and he confessed frankly, for his own part, that when he read the numbers he was rather astonished, because he did not think that, whatever the sins of the Corporations of Scotland might have been, they were *not* sins of that deep dye which called for such reproof as was embodied in these numbers." It was not in the disparity of numbers in the Divisional Board that Dr. Leishman considered that danger lay to the extra-mural schools; it lay in the deep-seated feeling which existed in England against the Scotch schools, as England had been jealous for many years of the surprising success of the Scottish schools, and he pointed out that whatever a medical board did was subject to a Medical Council—a board sitting in London, the majority of its members being always Englishmen. Scotland and Ireland would be in a minority,

and appeal from that board was to the Privy Council, and "they all knew what the Medical Department of the Privy Council was." Dr. Leishman is thus perfectly willing to take a gift of eight University representatives from these gentlemen, of whose sense of fairness in the matter of appeal he has such serious misgiving.

As a former lecturer of the Glasgow Extra-Mural School, Dr. Leishman fell into a singular error as to the long-continued hostility of the University towards "the Andersonian." He stated that the University was advised by the Lord President of the Court of Session that so long as the Andersonian University, which was the only extra-mural school then existing, called itself a University, without having a charter, it could not be recognised. Dr. McVail cogently points out, in reply to this, that the University of Edinburgh was under the same legal enactments as that of Glasgow, and that it did not refuse recognition of the lecturers of this school, and that, in point of fact, the change on the part of the University towards its rival had no relationship whatever to the change of name or constitution, as it took place *prior* to that event by about two years. Dr. Leishman's advocacy of the University being, therefore, as we believe, about the best possible, it simply serves to show the inherent weakness of the case he defended with such success as a pleader.

Notes on Current Topics.

Chloroform Narcosis During Sleep.

A CORRESPONDENT of our New York contemporary, the *Medical Record*, having recently given expression to doubts concerning the possibility of inducing chloroform narcosis in sleeping persons, communications affirming the opposite have been contributed to the same journal by other observers. These are of considerable interest on account of their being illustrated by records of actual experiments purposely made with a view to solving the problem, Dr. Davis Haldermann adducing two successful instances in which he himself was the operator, and Dr. E. M. Nelson one. These examples added to those previously recorded sufficiently establish the truth of the statement which has been called in question; and the subject possess also an interest which entitles it to consideration. Not very long ago it arose in this country in connection with the performances of burglars, certain of the more daring of whom were popularly charged with invoking chloroform to their assistance while carrying out their designs. On the evidence proffered by the physicians named above, however, it is shown that to be successfully applied the narcotic must be very gradually and cautiously brought within breathing distance of the subject of the experiment, the cloth or other instrument must be held at first as far as two feet away from the sleeper's face, so sparingly to dilute the atmosphere for some distance around, with the primary object of blunting the air passages, and thus avoid the liability of reflex disturbances, the abrupt excitation of which leads to failure in those trials which fail of success. The practical application of this method of narcosis is well shown by one of the cases quoted, that of a boy on whom the operation of circumcision was performed during insensibility produced while

the patient was asleep in bed. Children offer peculiarly favourable subjects in this respect, and by pursuing such a course with them much terror and apprehension caused by preparations made in their waking presence might be happily avoided.

Voters in Irish County Infirmaries.

QUESTIONS have arisen, in connection with the recent election of a surgeon to the County Roscommon Infirmary, as to the period at which the subscription of a governor ought to be paid to entitle him to vote in the election. On looking into the law of the matter, we find that by the 3rd section of 47 George III., cap. 50, passed in 1807, "Every donor of any sum not less than twenty guineas . . . shall, from the time of such donation, be one of the governors or governesses, and a member of the body corporate of such respective infirmary . . . for one year from the day of the payment of such subscription." By the 4th section of a subsequent Act—54 George III., cap. 62—it is provided, "That no annual governor or governors of any such infirmary shall be permitted to vote at the election of such infirmary upon any vacancy in such office (the surgeoncy) unless he shall have paid the subscription by virtue of which he claims a right to vote at such election two years at the least before any such vacancy shall have occurred." By the 9th section of 3rd and 4th William IV., cap. 92 (1883), this latter limitation is altered to one year. It thus appears that no one is entitled to vote in respect of any subscription paid subsequently to a year before the death or resignation of the surgeon. This is a strange limitation, and, it seems, might be read so as to exclude the votes of all annual subscribers, because, as the election must necessarily take place after the death or resignation, none of them could possibly vote until after the twelve months preceding the vacancy had lapsed; and if they voted at all, they must do so in respect of the previous year, and not the current year's subscription.

The Parkes Museum.

THE Council of the Parkes Museum of Hygiene, which is now definitely located in its new home at 74A Margaret Street, Regent Street, W., has just issued a circular letter setting forth the objects to forward which the institution has been founded, and inviting the hearty co-operation of all who are interested in the progress of sanitary science. The most effectual support that can be afforded, and such as can be rendered by all who have the will to proffer it, may be given in the assurance that good will result; and by enrolling themselves as members of the Museum, profession and public may alike contribute to the success that is so well merited. The annual subscription for members is one guinea; or a life composition of ten guineas confers the privileges of membership, including free use of the museum, library, and reading room, and admission to lectures and demonstrations. Several of the latter have already been given, in the presence of considerable and appreciative audiences, and a programme of other similar meetings is arranged for the current session. It is to be hoped that an ungrudging support will be accorded to the Museum, and all who desire to obtain further information concerning it may do so on application the Hon. Secretary, Dr. Dawson Williams, at the institution.

Nitrous Oxide for Prolonged Anæsthesia.

THE only method of administering nitrous oxide for prolonged anæsthesia, so far successfully used, has been to use it mixed with air or oxygen at considerably more than ordinary atmospheric pressure, which required the immersing of the patient, operator, assistant, &c., in an isolated condensed air chamber. On the 30th of April last, however, M. Bert described, before the French Academy of Science, experiments upon animals, with a view of accomplishing the same end by the *alternate* exhibition of the nitrogen protoxide and oxygen gas at the ordinary pressure. It was only necessary to connect with the ordinary mask or inhaling facepiece another tube from a bag of oxygen. When insensibility is produced by the laughing-gas, oxygen is for the moment given to avert asphyxia. This reoxydises the blood sufficiently to allow the nitrous oxide to be continued, without restoring sensibility. By these means, animals—such as dogs—were kept alive and insensible for half-an-hour or more without bad after-results.

Research Rewards in France.

THE treatment of M. Pasteur by his countrymen offers a striking example of the gratitude of a nation for benefits conferred on it as a result of scientific research, and might not inappropriately find imitation in other countries than France. A committee having been appointed by the French Parliament to consider the question of the pension awarded to M. Pasteur by the Government, and which has hitherto been £450, has recommended that the amount be increased to £1,000 per annum, and that it should revert to the widow and children of the *savant* after his death. As a mere return for the services it acknowledges no money payment could, of course, be sufficient; but as an evidence of grateful appreciation the action thus taken by the committee is eminently encouraging to research.

Sanitary Insurance in Dublin.

A SPECIAL general meeting of the Dublin Sanitary Association was held on Monday week, for the purpose of amending the rules of the Association so as to enable it to place the benefits of "sanitary protection" within the reach of its members. On the motion of Dr. Grimshaw, the Registrar-General for Ireland, it was resolved, "That the following (fifth) object be added to the four for which the Association was originally founded, viz.:—To provide its members, at moderate cost, with such advice and supervision as shall insure a proper sanitary condition of their own dwellings, and enable them to procure practical advice as to the best means of remedying the defects in the houses of the poorer classes in which they are interested."

This is an admirable addition to the usefulness of the Association, and we have no doubt the sanitary insurance which is offered will be largely availed of by the Dublin public. We hope, however, that the executive of the Association will instruct its sanitary inspectors to keep their suggestions within practical bounds, for we know as a fact that house proprietors are usually deterred from calling in a sanitary adviser by apprehension that they will be called upon to undertake large, troublesome, and expensive works.

No doubt it is good policy to make the sanitation of a house quite perfect when it needs reconstruction, but such a proceeding is seldom within the means of a house-owner, and never within his inclination, while he may be perfectly willing and able to effect useful changes. When the sanitary insurance system develops in Dublin—as we hope it will—it would be a great matter if the Association could arrive at a price list, or approximate estimate of cost of works, for there is no class of tradesmen so much feared by the public as sewer-doctors, and none whose work is, generally, worse or more exorbitant in cost.

Professorships at Cambridge.

APPOINTMENTS have recently been made at Cambridge to the new Chair of Physiology founded as a result of the Royal Commission, and to that of Anatomy vacated by the resignation of Dr. Humphry, who has generously taken over the duties of Professor of Surgery without stipend. To fill the Physiology Chair, Dr. Michael Foster has been chosen, and no more fitting occupant could possibly have been selected. Dr. Foster, moreover, has so identified himself with the teaching of this branch of science in the University that any other selection would have appeared almost unnatural. His services have amply merited this recognition of them; to have lost them from any cause would have been an irreparable blow to the great school whose fortunes he has so materially advanced. The second professorship, that of Anatomy, has been offered to and accepted by Dr. Alexander Macalister, Professor of Comparative Anatomy and Zoology in Dublin University.

The Practical Result of the Anti-Contagious Act Agitation.

DR. A. CONAN DOYLE, of Portsmouth, writes to the daily papers to the following effect:—

“As an ounce of fact is proverbially superior to an indefinite quantity of theory, I think that I am justified in citing one or two instances of the effects of the present suspension of the Acts. Being in practice as a medical man in the town most affected by the measure, I am able to speak with some authority on the subject. Last week a large transport entered Portsmouth Harbour with time-expired men from India. Upon the same day several diseased women left the hospital presumably with the intention of meeting that transport, and there was no law to prevent it. I say that if an unfortunate soldier, coming home to his native land after an absence of years, and exposed to such temptations, should yield to them, and entail disease upon himself and his offspring, the chief fault should not lie at his door. It surely emanates logically from those hysterical legislators who set loose these bearers of contagion, and their like, upon society. For fear delicacy should be offended where no touch of delicacy exists, dreadful evils are to result, men to suffer, children to die, and pure women to inherit unspeakable evils.”

It is truly a subject for just indignation that the moral hallucinations of a few misguided philanthropic theorists should have induced the Government to deprive the public of the protection which these Acts afforded, and this in the face of the repeated judicial decisions of Committees of Parliament that these Acts were necessary to the public weal, and a hardship on no decent member of society. The subject is one in which our profession may reasonably be looked to to take a strong position, and the

present circumstances are such as to call for vigorous action. Agitation can only be met by counter-agitation, and as the promoters of syphilis infection have succeeded in creating a false idea in a section of the public, and in squeezing the Government, it becomes urgently necessary for the profession to educate the public as to the utter falsity of the statements made by these anti-Act fanatics. We therefore urge our brethren to throw themselves with enthusiasm into the effort to restore to the public the benefits of protection against syphilitic disease. The Society for promoting the extension of the Acts is ready for work, but it needs increased moral support, and the sinews of war, and our profession is bound to give that aid. A brisk campaign between this and next session of Parliament would, we fully believe, lead to the restoration of the grant for carrying the Acts into effect which has been withdrawn by the Government.

Physiology at Oxford.

THE advent of Dr. Burdon Sanderson to Oxford in the capacity of Waynflete Professor of Physiology has naturally led to vigorous exertions on his part for speedily providing the University with increased laboratory accommodation in keeping with the advances made by modern scientific methods and research. At a late meeting of Convocation, therefore, a proposal to apply the sum of £10,000 from the University chest, for the purpose of supplying the new professor with working room, was brought under discussion, and raised, as might be expected, much opposition among the clerical party, who chiefly objected to facilitating vivisection, this being, in their estimation, the logical outcome of physiological instruction. Fortunately for the credit of Oxford as much as for the advantage of study, the attempt to withhold the vote was a failure, and it was eventually carried by a narrow majority of 3, 88 voting for, and 85 against, the motion. There is now a fair prospect that Oxford will become a worthy rival of Cambridge in the work done by its members in behalf of experimental science.

“Infamous Conduct in a Professional Respect.”

AMONGST the light thrown upon the trade in fictitious lecture and hospital certificates, by the recent discussion in the Dublin College of Surgeons, a remarkable statement made by Mr. Macnamara, representative of the College on the General Medical Council, deserves special notice. Mr. Macnamara, speaking officially and authoritatively on behalf of the Medical Council, stated that, while that Council did not wish to place a restriction on the hour at which lectures might be delivered, it was unanimously determined to treat the issue of a fictitious certificate—if proved against any teacher—as (to use the words of the Act of Parliament) “infamous conduct in a professional respect,” and to punish it rigorously by erasure of the offender's name from the Register.

This is truly a new departure, considering that the five Irish members of the General Medical Council must for years past have been thoroughly conscious that this “infamous conduct” was of every-day notoriety, and considering that the evidences of its prevalence were to be found in the Council's own minutes.

In order to be prepared with evidence on the point, we should like to know what the Irish Branch Council would consider sufficient proof of the falsity of a certificate? Would it suffice them to have evidence of a sheaf of certificates of diligence signed by a teacher who never delivered a single lecture of those certified, and never saw the face of one of the students of whose diligence he testified?—would it convince them if proof were presented of a gentleman who within a comparatively recent period obtained the highest qualification of an Irish licensing body by virtue of a certificate which he bought for £3 3s. from a school where his name was never even entered for the course, such certificate being ante-dated 15 years by the vendors to suit the period of his studentship? or would they prefer evidence of the "diligent" attendance on a Dublin *annus medicus* by a student resident for that period in Australia?

The pretence of unconsciousness comes too late, for we can answer for it that—if the five members of the Irish Branch Council and its Registrar were in innocence of the wholesale trade in fictitious certificates in Dublin—they are the only six gentlemen in the Irish medico-educational community so ill-informed.

Mercuric Chloride as a Germicide.

A VERY interesting summary recently appeared in the *Practitioner* of a paper by Professor Koch, giving the results of some investigations into the comparative value of disinfectants, or germicides. He found that, as regards the action on bacteria, bacilli and micrococci, by far the most potent disinfectant was corrosive sublimate; a solution of 1 per 1,000 of mercuric chloride killed the strongest of these at once, whilst even solutions of 1 in 10,000 and 1 in 15,000 were sufficient to destroy many micro-organisms. He remarks that the poisonous action of such dilute solutions may be entirely disregarded. A five per cent. solution of carbolic acid, used under the same conditions, was ineffectual. Salicylic acid and thymol were about equal in value to carbolic acid. Other mercurial salts, as the sulphate and nitrate, were found to be quite as efficient as the chloride. A French chemist, M. de la Croix, who has been making experiments of a somewhat similar nature, arrives at nearly the same conclusions.

A Medical Reserve Force.

THE French Minister of War has just declared that he considers it quite indispensable for doctors and apothecaries to practise in time of peace the duties which are necessary in war, and he has requested the Minister for the Interior to inform him under what conditions these functionaries can be called together for this purpose. At present they are only obliged to appear once a year, at a fixed date, before the Controller of the Medical Department. The *Temps*, which gives this information, thinks that it would be advisable to call out at the same time both the doctors of the reserve and those of the active force, as by this means the former would be aided by the latter in the explaining of the various duties, and would also become acquainted with the details of military life. The reserve numbers about 900 doctors and 100 dispensers.

Scotch Licences.

THE Scottish correspondent of the *Lancet* says, last week:—As an evidence of how the wind blows, it may be mentioned that in the last published list of those receiving the licence of the College of Physicians, Edinburgh, only one had residence in Scotland. Of the eleven, eight were from London, one from Bristol, one from Canada, and one from Glasgow.

The Prospects of the Medical Bill.

THOSE whose "wish is father to the thought" have been gratifying themselves by circulating a rumour that the Medical Bill will not be proceeded with this session, for which statement we believe there is no better foundation than the backward state of the session. We have authority for saying that the Vice-President of the Privy Council, who has charge of the Bill, never had the least idea of dropping it, and that it will be placed on the notice paper *au sérieux* on the first opportunity which can be got.

The Briton Medical Life Assurance.

THIS Association, which has always been largely patronised by the profession, has just issued its annual report, which is of a decidedly favourable character. No less a sum than £21,573 was received from premiums during the year, and £4,708 constituted the new business. We hope the new business is chiefly from insurance of medical men, as it would thus afford practical evidence that they were becoming more alive to the necessity of life assurance in providing for the proverbial rainy day.

Stronger testimony in favour of total abstinence could scarcely be desired by its most ardent advocate than is found in the report before us, where the directors state that after mature deliberation they have decided to offer the advantages of lower rates "to total abstainers from alcoholic beverages." From a pecuniary point of view the Briton Life Association is in a decidedly favourable position, as the directors are able to recommend that a dividend of 5 per cent. on the balance of the capital be declared, free of income tax, out of which an interim dividend, for the first six months, has already been paid.

The Poor-law Superannuation Bill.

A PARAGRAPH appeared last week in the *Freeman's Journal* to the effect that at the meeting of the Irish Parliamentary party a lengthened discussion took place on the report of the sub-committee appointed to examine the Poor-law Officers' Superannuation Bill. The general feeling of the meeting was against allowing the Local Government Board the power of interfering with the superannuation allowances granted by the guardians. A conversation also took place as to the desirability of introducing an amendment giving the boards of guardians discretionary power in fixing the amount of the allowance and relieving them from the compulsion proposed to be placed upon them by the Bill of adhering to the scale contained in it.

We are glad to be able to state our belief that the views here expressed are not those either of the leaders of the Irish party or a majority. Discretionary superannuation could not be for a moment thought of by those who

are promoting the Bill, and, moreover, it will not be tolerated by the Government, inasmuch as the Bill would be entirely valueless as a settlement of the difficulty if guardians were empowered to do as they pleased with their officers' pensions. We believe that Mr. Herbert Gladstone will make any reasonable or possible concession to meet the opposition of Mr. Biggar and his party, but—if it be not found possible to do so—the Bill will be pressed to an issue this session in spite of their blocks.

Telephonic Night Service for Dublin.

THE Telephone Company has announced that on and after Monday last the exchange will be kept open night and day. Thus the chief difficulty in the way of the employment of this method of medical inter-communication is removed, and we hope to see, as a consequence, the extension of the wires to all the hospitals, and most of the practitioners of Dublin.

Factory Inspectors.

A CIRCULAR has been issued by Mr. Redgrave, the Chief of the Factory Inspection Department, asking certifying surgeons to make a return of the number of firms with whom contracts are made by them for periodical visits, and how much they are worth, and also the value of the fines received. This is a movement by the authorities which, however inconvenient to individuals, must be approved in the public interest. The truth is that the Act of Parliament intended that the certifying surgeon should be altogether independent of the factory owner, and it set down a tariff of fees payable for periodical inspection. But, after a time, it came to be tolerated by the central department (and therefore usual with certifying surgeons) to contract themselves out of the provisions of the Act and make private arrangements with the factory owners such as would be mutually comfortable. The effect of this laxity was to make the surgeon, more or less, the *employé* of the owner, and to make him unwilling to vex the owner by any excess of official enthusiasm, *et hinc illæ lacrymæ*, abuses have crept in and the central department is called upon to move in the matter.

The Pathogenesis of Uræmic Eclampsia.

DR. SNYERS, of Liege, has recently submitted the various theories as to the origin of so-called uræmic accidents to an experimental examination, carried out in Stricker's laboratory in Vienna, with the result that each was shown to be untenable. The various theories examined and rejected in turn were—(1) that of Wilson, who held that the uræmic symptoms depend on retention and accumulation of urea in the blood; (2) that of Frerichs, that they are caused by the change of urea into carbonate of ammonia. The author concluded that the quantity of carbonate of ammonia in the blood of uræmic dogs was far too small to cause death. (3) That of Schottin, to the effect that the effete material accumulates in the blood before it becomes changed into urea. This also was rejected. (4) That of Traube who held that the symptoms are produced by œdema and consecutive anæmia of the brain. The author found that if increased blood pressure was avoided, œdema of the brain failed to produce the

symptoms. (5) That of Feltz and Ritter, who believed that the potash salts of the urine were the agents of uræmic intoxication. The author concluded that the amount of potash salts in the blood was too small for the symptoms to be fairly attributed to them. He also examined the blood in two cases of puerperal eclampsia and failed to discover any increase in the amount of the potash salts. The author remarks in conclusion that none of the present theories suffice to explain the whole train of symptoms of uræmia. This is quite true of the theories passed under review by the author, but another theory recently set on foot, in which the above train of symptoms is attributed to nervous causes, the so-called uræmia playing but an accidental and secondary part, or even no part at all, would seem to be supported in a negative manner at least by our author's observations.

Ready Method of Intravenous Injection.

IT appears certain that the intravenous injection of saline fluids in cases of acute general anæmia has a great future before it. One obstacle to the more extended employment of this eminently conservative operation has been the absence of suitable and inexpensive apparatus. It is true that we have had quite recently brought before our notice apparatus well adapted for the purpose, and of moderate price. It is still uncertain, however, whether any great number of practitioners will care to spend even so small a sum as a couple of guineas on the purchase of an instrument they may never have an opportunity of using. Under these circumstances it will, perhaps, be interesting to learn how intravenous injection has been performed in a case of emergency, in which no specially designed apparatus was at hand. Such a case occurred in the practice of Dr. L. Szuman, of Thorn, and is reported in the last number of the *Berliner Klinische Wochenschrift*:—The patient was a youth, 15 years of age, who had met with an accident, resulting in serious hæmorrhage, likely to prove fatal. An apparatus for intravenous injection was extemporised on the spot, and the injection made, with a happy result. A piece of fine drainage tubing, not perforated, was attached to the nozzle of an irrigator (a flat old-fashioned infant's feeding bottle would answer the purpose very well.) The solution employed was—water 1000 grm., table salt 6 grm., and bicarbonate of soda 1 grm. The left median vein was exposed, separated by passing under it two hollow sounds, a trocar 1½ mm. in diameter was then introduced until the point of the stilette was well in the vein, when the stilette was withdrawn a little. The canula was then pushed in to a depth of about 1½ ctm. A ligature was then applied round the vein over the canula, the stilette withdrawn, and the tubing drawn over the free end of the canula. The irrigator was then raised about 1 metre in height. When the solution flowed into the vein, 760 grms. were employed. After the injection was completed the vein was ligatured on the peripheral side of the puncture. The operator is to be congratulated on his ability to make use of such apparatus as was at his command, and by means of it tide his patient over a danger that would most likely have proved fatal but for his readiness in thus adapting simple means to an unusual purpose. Let us hope that the lesson thus taught may not be taught in vain.

injury is flexion of the knee before the patella is quite sound. This is proved by every-day experience. How often we find cases discharged from hospital after two, three, and four months' sojourn where patellar union seems all but perfect, and yet a very few weeks of free use of the limb, with or without knee-cap, is sufficient to make both the surgeon and patella gape. Previous treatment cannot be blamed for it, but the surgeon may be justly censured for permitting movement where its evil result is manifest. In Mr. Parson's case the result does not wholly justify the means, for we have abundant proof of the recovery of many patients from similar injuries left to the tender mercies of sea captains. Isolated cases of good results will occur whatever the treatment; the danger lies in the confusion of the "propter" with the "post hoc." Mr. Parson adds, "slight movement of knee in walking about prevents a stiff joint." This I emphatically deny, and the proof is contained in two propositions:—1st. Inflammation is a necessary precursor of ankylosis. 2nd. Inflammation is increased in a knee when moved. In a given case the worse the inflammation the greater the danger of ankylosis.

The advantages claimed for Thomas's method are freedom from confinement and efficiency of cure. With the splint on the patient is free to follow his out-door habits in a couple of days after his accident, and that without the slightest risk. The apparatus forms a convenient form of perineal crutch, which withholds all flexion at the knee. A few days back, at the Stanley Hospital, I removed a Thomas's splint off a corpulent old dame who had worn it five months. To-day movement at the knee was very fair; next week it will be nearly well. The fragments, which were two inches apart, are now in perfect apposition; but the method I adopted saved me from all apprehension from the first. Yesterday week I removed two splints which had been for two years correcting genu valgum, during the whole of which time no movement was permitted to the knee-joints. To-day movement is nearly perfect. This is only one of several instances. I have seen upwards of twenty cases of fractured patellæ treated by Thomas's method, and never yet a stiff joint resulting. To ensure permanency of cure it is often necessary to wear the splint six months, and patients rarely complain of discomfort meanwhile.

I am, &c.,

ROBERT JONES,
Senior Assistant Surgeon,
Stanley Hospital.

22 St. George Square,
Liverpool, June 21.

THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your journal of June 13th and 20th you gave great prominence to the false statement of Mr. A. Conan Doyle, M.B., respecting the departure of diseased women from hospital in Plymouth. You appear not to have seen his acknowledgment that this statement was an error, or you would doubtless have given equal prominence to the contradiction.

Surely the solution of a grave social problem, involving the highest moral and physical welfare of our country, can never be attained by the spread of falsehood on either side! In judging this question, it would be well if every member of the profession would carefully read "Le Péril Venerien dans les Familles," by Dr. P. Diday (published by Asselin and Co., Paris). The perusal of this work, written by an experienced French surgeon, must arrest the attention of every unprejudiced Englishman. It shows the practical results which follow from working for several generations on a false principle.

This false principle (of which the author is a follower) is the refusal to check whoremongers, whilst endeavouring to regulate whores. The pitiful stultification of judgment which results from frantically endeavouring to establish this false principle is only equalled by the astounding cynicism which such a foolish contravention of law produces.

Both these results are strikingly shown by this and other lately published French medical treatises.

I am, Sir, yours, &c.,

A CONSTANT READER (but a believer in
the oneness of medicine and morality.)

The following is the contradiction referred to:—

The Secretary of the National Association for the Repeal of the Contagious Diseases Acts, having had the letters of Mr. Doyle to *Daily Telegraph*, June 8th, and one from S. U.

Thompson, June 9th, brought to his notice, wrote to Mr. Doyle, pointing out that, as the Acts had not been repealed, and the compulsory detention in hospital had not been suspended, his "ounce of fact" was an evident fiction. Mr. Doyle replied: "I am glad that you have called my attention to my error as regards the dismissal of women from the hospital. I had the story from two members of the Visiting Committee, but Dr. Snowdon, the indoor officer, assures me that there is no foundation for it. I have, of course, written a contradiction of it to the paper."

Mr. Conan Doyle, M.B., C.M., of Portsmouth, writing in reference to the letter from him which was published in the *Daily Telegraph* of Friday last (June 8th), says: "I find that one error has crept into my statement of the increased immorality since the suspension of the Acts. It is not correct that thirty women left the hospital with the avowed intention of meeting a transport. The error arose from the misconception of some remarks made by a gentleman intimately connected with that institution." Mr. Doyle adds that this error in no way affects his general argument—"the difference in the streets of Portsmouth is most marked, and grows worse."—From the *Daily News*.

Novelties.

AN ELECTRICAL PHOTOPHORE.

At a recent meeting of the French Académie de Médecine, M. Dujardin-Beaume presented an electrical "photophore," invented by M. Paul Hélot, chief surgeon to the hospital at Rouen, and M. Trouvé. The apparatus consists of an

incandescent lamp contained in a metallic cylinder, between a reflector and a convergent lens. This small instrument when fastened on the forehead gives a very intense light, and can be adapted to the field of vision by moving the lens. When placed between the eyes, the light, as it were, accompanies the view of the operator, as there is nothing to interfere with it. The source of the electricity is a voltaic pile of bichromate of potash supersaturated. It lasts many hours without being re-charged, and can be used either continuously or at intervals. This apparatus will be found most useful in examinations of the mouth, throat, ears, &c.

AN IMPROVED NURSERY POWDER.

The importance of a pure, non-irritating, and innocuous nursery powder is so generally recognised by the profession and the public alike that the addition of a reliable article of this kind to those already in use is of some consideration. Messrs. Woolley, Sons, and Co., of Manchester, have introduced a new "sanitary rose powder," which is not inappropriately named "the perfection of nursery powders," and which possesses the unique and highly valuable property of being soluble in water, so that the annoyance produced by caking is altogether avoided by its use. The powder is also antiseptic, and is, in very many respects, a great improvement on those in general use. Its employment, in nurseries particularly, may be strongly recommended.

officials were all re-elected. Dr. Lawrence was unanimously appointed first medical officer for the Infirmary, and Dr. Kay assistant medical officer.

NEW DISTRICT LUNATIC ASYLUM.—At a meeting of the Lunacy Board of the county of Lanark, held in the Council Chambers, Glasgow, on the 13th inst., the Committee concluded the final arrangements with Mr. Peter Forrest, of Shotts, for the acquisition of his lands of Hartwood and Bow-housebog, of about 500 acres. At the same time, arrangements were made for purchasing two small adjoining properties, which will bring up the total area to about 600 acres, at a total cost of £26,500. The distance from Glasgow is about fifteen miles by rail. When completed, the new asylum will be on an extensive scale, and fitted up to accommodate 900 to 1,000 patients. The ultimate cost, we learn on good authority, will be not less than £150,000.

DIPHTHERIA AT FETTES COLLEGE.—In consequence of the occurrence of two cases of diphtheria at this institution, it has been thought desirable, as a measure of precaution, and to prevent any chance of the spread of the disease, to dismiss the boys for a time. It is to be hoped that a careful inspection of the sanitary arrangements of the building will be made, so as to prevent a recurrence of the disease.

THE LATE MRS. JAMES BUCHANAN.—As a munificent contributor to and founder of medical institutions and scholarships, beside many objects of a humanitarian character, this estimable lady, who has just died in Edinburgh, in her 86th year, deserves more than a passing record. Mrs. James Buchanan was well known as one of the earliest and largest contributors to the new Royal Infirmary, and one of the medical wards there bears her name. Three years ago Mrs. Buchanan presented £1,000 to the University of Edinburgh for the foundation of a scholarship in Midwifery and Gynaecology, and had the satisfaction of being visited by the first two Buchanan scholars. During her long life she took a special interest in, and contributed liberally towards, the construction and support of drinking troughs in London and elsewhere. But her philanthropic and humanitarian endeavours to do good were not confined to her own country. She built, and has supported for many years, a school in Swatow, China, for the education of Chinese girls. The Buchanan Institution in Glasgow, which was founded by her husband, received many proofs of her liberality. She built a handsome dining-hall for the boys, in which has been placed a marble bust of herself, by the late William Brodie, R.S.A.

ROYAL INFIRMARY, EDINBURGH.—At a meeting of the managers of this institution, held last week, it was reported that there had been received from the Edinburgh Football Association a sum of £100, the amount allocated to the Infirmary from the money drawn at the various matches for the Charity Cup, presented to the association by Lord Rosebery.

A BELIEVER IN DRUGS.—The subjoined prescription was recently dispensed according to the direction of a medical man by a Glasgow chemist and druggist:—

R Potass. iodidi, gr. iv.;
Potass. nit. ℥ss.;
Potass. chlorat. ℥ss.;
Calc. hypophos. ℥j.;
Sodæ hypophos. ℥j.;
Ferri ammon. cit. ℥ij.;
Ext. ergotæ liquid. ℥v.;
Vin. ipecac. ℥iss.;
Tinct. digitalis, ℥iss.;
Tinct. nucis vomicæ, ℥iss.;
Syrupi zingib. ℥j.;
Aquæ chloroformi ad ℥vijj.;

Sig. A tablespoonful shortly before each meal.

Will any one dare to doubt that there is such a science as that of medicine after this?

IMPORTANT MEETING IN GLASGOW ON THE MEDICAL ACTS AMENDMENT BILL.

A PUBLIC meeting, called in terms of a requisition to the Lord Provost, was held in the Merchants' House, Glasgow, on the 15th inst., to consider the Medical Acts Amendment Bill now in the Commons, more especially in respect to the clauses constituting the Medical Board for Scotland, so as to consist of eight University and three Corporation representatives, thus creating in favour of the Universities a monopoly which would be detrimental to the Extra-Mural Medical Schools by extinguishing freedom in medical teaching.

Lord Provost Ure, who was called upon to preside, explained the steps taken to call the meeting.

Mr. John M'Laren, moved the first resolution:—"That this meeting views with regret the constitution of the proposed Medical Board for Scotland, as from the great preponderance of the University nominees, it is likely to tell prejudicially on the extra-mural school for Scotland." After explaining the nature of the proposed Medical Board, the speaker went on to say that Scotland was not to have a fair representation at the Board as compared with England or Ireland. England was to have a board of 116 members; 8 of these were University professors, and 8 medical corporation. Ireland was to have a board of 11-6 from Universities and 5 from medical schools. Well, Scotland was to have a board of 11, of which the large proportion of 8 was from the Universities, and only 3 from the Medical Corporation. This, upon the face of it, appeared to be unfair. He therefore moved this resolution.

Dr. Leishman took exception to many of the statements that had been made, and said that he could find nowhere in the Bill anything which could create a monopoly not previously existing. There might be something in the monopoly already existing; but there was none that he saw created, nor could he see in any sense that the freedom enjoyed by the extra-mural teachers was to be deprived by this new Board. After going into details, he said he thought the real danger to the Bill in Scotland was a different one from what was stated here—the real origin being a deep-rooted feeling of hostility which existed in England towards Scotch schools, whose surprising success they had been jealous of for many years. He did not intend to move an amendment to the resolution, but would content himself with the remarks made.

The resolution was then agreed to.

Mr. William M'Ewen moved the next resolution, to the effect that as there was no arrangement under which extra-mural schools could be directly represented on the Medical Board, other than through the medical corporations, this meeting is of opinion that the latter should be equally represented with the University as a Medical Board, and at least one half of the Corporation nominees on the Board should be extra-mural teachers.

Provost Brown having seconded this resolution,

Dr. Young moved as an amendment—"That in the opinion of this meeting it is desirable that the extra-academical teachers of Scotland should have a direct representation on the Medical Board of Scotland by three of its own members."

The amendment failed to receive a seconder, and the motion was declared duly carried.

Mr. Stephen Mason moved—"That in the opinion of this meeting it would be unjust to the extra-mural medical schools, and would tell disastrously upon them, that their students should be compelled to pay to the Medical Board a larger fee than the students of the Universities."

Dr. Leishman supported the resolution, which was adopted.

Baillie Wilson moved "That the resolutions that had been put before the meeting should be drawn up in the form of a petition, signed by the chairman of the meeting, and presented to Parliament by the Members for the City."

Mr. Muirhead seconded, and it was agreed to.

Mr. Fleming said it ought also, at the same time, be represented that the meeting was not a fair representation of the medical profession in Glasgow, as it was composed mostly of extra-mural teachers. ("No, no.")

The Chairman: Well, it has been publicly enough advertised, and if the citizens of Glasgow did not turn out in their thousands it cannot be helped.

Baillie Watson moved a vote of thanks to the Lord Provost for taking the chair, which brought the proceedings to a close.

Literature.

QUAIN'S DICTIONARY OF MEDICINE. (a)

MEDICAL literature has received no addition at all comparable to Dr. Quain's "Dictionary" since the appearance of Copland's well-known work, the excellence of which has necessarily excited a considerable amount of expectation in regard to the merits likely to be shown by a new labour projected on similar lines. With the certainty of comparative criticism before him, therefore, it is by no means unlikely that an editor of even Dr. Quain's universally recognised ability may have been anxious for the result of his efforts; and in the exhaustive treatise with which his name will henceforth be always associated, we are able to discern abundant evidence of that careful, conscientious, and thorough workmanship which is impressed on all that emanates from him.

The modern science of medicine borrows largely from the genius of its individual promoters; each physician who devotes himself to the careful analysis of a particular disease or class of diseases succeeds in stamping its treatment for the time being with marks characteristic of his particular views; and in every case where a teacher with a recognised following has thus lent himself to be the enunciator of special views, they have, so long as his influence has continued to exert itself, been followed to the advantage of humanity and the alleviation of suffering. We owe perhaps more than can readily be estimated to Dr. Quain's acute perception of such influences and the bearing they have on the progress of science, and to the facility this perception offers for securing the most able assistance in producing the work already familiar to the majority of medical practitioners. In writing the "Dictionary" Dr. Quain has obtained the service of more than one hundred and fifty of the leading physicians and surgeons of our time, not all of whom, alas! have lived to see the final acceptance of their efforts at the hands of the general profession. The busy hand of death has thinned even the small band associated with Dr. Quain to an all too appreciable extent; and once more we are called on to mourn the loss, emphasised afresh by the lines, in many cases the last they ever wrote, which stand over the names of Parkes, Murchison, Callender, Peacock, Cormack, Lockhart Clarke, Tilbury Fox, Hayden, Leach, Silver, Clover, Irvine, Seaton, Sparks, and Stephen H. Ward. This list indicates, moreover, the length of time during which the work has been in preparation, and from the size and importance it presents it can be readily understood how impossible it must have been to conclude it in any shorter term.

The work is what its name indicates, a *dictionary of medicine*, in which, under the names of various diseases alphabetically arranged, is included a full description of all recognised ailments as regards etiology, symptoms, course, duration and termination, diagnosis, prognosis, and treatment. The characteristic lesions presented under each form of disease are also described as far as is consonant with existing knowledge; and unique importance attaches to the essays of which the volume is in the main composed, from the fact that each bears the signature of the author contributing it, of whose individual research and opinions it is consequently a valuable reflex.

The task of reviewer, when extended to such a monumental production as the "Dictionary," necessarily becomes a most difficult one. When the plan and scope of the book have been explained, there remains but little to be achieved in the direction of legitimate criticism, for the most careful examination of the articles suffices to exhibit no more than points which at the most are matters of personal difference, rather than important departures or omissions. But turning to subjects which have assumed especial prominence in the recent history of medical science, we are afforded opportunity both of observing the minute care with which every matter deserving of notice has been included in the work, and of commenting on the opinions expressed by the authorities responsible for their treatment. Thus, Dr. Ord very fittingly contributes the article on Myxœdema, but owing probably to the revision of his proof sheets having preceded the issue of the "Dictionary" for some time, he confines

the appearance of the disease to adult womanhood. The occurrence of myxœdema in males has now been recorded more than once, and very recently three children have been exhibited in London in whom the appearances of myxœdema were most markedly present. The disease itself is very instructive, and its history more so, as showing the fallacies that lurk under the description of any hitherto unrecognised disease as "new." Under the heading of "Shock," Sir William MacCormac has an able and sufficiently brief essay to convey a lucid and adequate notion of the condition and its consequences; the definition he gives is a very useful one, and though it may be objected that it opens the door too widely to any and every systematic change attended with depression, yet for practical purposes it would be difficult to improve upon it. Sir William MacCormac is not able to add much in the way of pathological details to what is generally accepted on the subject; but he nevertheless faithfully and completely recounts the *modus operandi* of the phenomena associated with shock, invoking, as of necessity, the physiological elements of the problem. As aids to treatment, transfusion is recommended in *extreme* cases of hæmorrhage only, and stimulation of the phrenic nerve and epigastrium by means of electrodes externally is suggested when respiration has ceased or is failing.

Dr. H. Charlton Bastian naturally takes his stand, when contributing under the title "Bacteria," on the ground that the germ theory of disease is materially allied with the question of spontaneous generation, so that the study of the former to the neglect of the latter "can only end in the propagation of vagueness and uncertainty." He further continues: "The real question is not as to the extent or frequency of the co-existence of organisms with local or general diseases, but the much more important one as to the nature of their relation to such processes. If they act as invariable and sole causes, then their presence is a matter of the deepest interest and importance. If, on the other hand, the organisms are not causes, but rather concomitant products, their presence from a purely medical point of view is of trifling importance. The study of their growth and development would in that case be important only as adding to our knowledge of the structural changes pertaining to the diseases in question."

In writing of "Germs of Disease," Dr. Bastian does not hesitate to display his want of sympathy with the modern school of germ theorists; and his faithful agreement with "auto-genetic" principles is equally well, though by no means ostentatiously, advanced. It would, of course, be unfair to expect an authority of Dr. Bastian's undoubted position and tenets to renounce his place as an advocate of special views entirely, and in the articles from his pen scattered through the "Dictionary" we cannot help but admire the excellent good sense and moderation displayed in dealing with subjects respecting which the author of them is so well known to be a holder of extreme opinions. As a summary of opposing views they are most instructive and intelligible, and, as far as such a thing could be under the circumstances, impartial.

The late Dr. Pearson Irvine has contributed a valuable essay on the causes of disease, in which the influences of age, heredity, intermarriage, sex, temperament, climate, and society, town and country, hygienic conditions, occupations, air, previous disease, mental and moral conditions, external physical conditions, poisons, temperature, diet, and epidemics, are considered in detail; and the complementary sections on personal health and public health are provided by Dr. Reginald Southey and the late Dr. Parkes respectively. This last named contribution takes rank as one of the most important in the whole work, being in fact a most admirably compressed *résumé* of the whole science of public health. It can be read with the utmost interest and profit by every medical man, whatever and wherever his practice may be, and will afford him endless and valuable help in the prosecution of professional duties.

Under the heading of "Hospitals, their Administration and Construction," Captain Douglas Galton contributes two very serviceable essays, the terms of which might with advantage be accepted as guiding principles by certain of our greater charities at the present time, and we shall possibly be doing a service to more than one general committee by commending to their perusal the remarks which Captain Galton makes in respect to management of hospitals and the various duties that properly fall to the lot of the medical staffs, matron, &c. The ripe experience gained by

(a) "A Dictionary of Medicine by Various Writers." Edited by Richard Quain, M.D., F.R.S., &c. London: Longmans & Co.

the writer of these articles, and his undoubted eminence in all pertaining to the construction of sanitary institutions, encourage anticipations of the excellence of his papers which they themselves fully maintain.

The diseases of the ear are treated of by Mr. Dalby; while Mr. Brudenell Carter undertakes the section relating to the eye. Epilepsy is described by Dr. Brown-Séquard.

As illustrating the rapidity with which the science of medicine advances the notice written by Dr. Lewis of *filaria sanguinis hominis* may be cited, no later reference than to accounts which appeared in 1877 being made, whereas since that date the life history of the entozoon, though still incompletely known, has been to some extent unravelled. Dr. Quain has, however, added a foot-note to Dr. Lewis's description, in which the researches of Dr. Manson are mentioned, researches which do much to enlighten us concerning the life-history of *filaria*.

A most excellent treatise on "Diseases of the Pleura" is from the pen of Dr. Clifford Allbutt. This work will probably take its place henceforth as the best *résumé* of the subject accessible to the student, and to whatever extent it may be employed in this respect, it will be fully deserving of the importance it attains. The sections dealing with the clinical characters and varieties of pleurisy are especially valuable and interesting, and they bring out the forcible characteristics of Dr. Allbutt as a teacher in a way that commands honest admiration. With a knowledge of the subject of pleurisy gained from careful study of this article and application of the principles laid down in practice the physician may confidently trust himself to do the best possible for such cases as may come within his treatment; and to students the sections cannot be too strongly recommended.

In selecting a few examples from the multitude of articles in the work, we have not sought in any way to indicate that they are instances of excellence elsewhere wanting. On the contrary, it is a characteristic feature of the "Dictionary" that every article in it is both authoritative and exact; the choice of authors has been a happy one, for in every case we recognise the acknowledged connection between the signatures appended and the titles of the sections to which they are attached. We have been compelled by the limits required in a review to instance the character of the whole work by describing the manner in which isolated portions of it have been carried out. In all respects the contents are of the high order of excellence naturally ensured when the pages of a work written by associated authors are throughout enriched with the result of experience gained by the best writers of our age.

To the excellence of Dr. Quain's own labours we need not further allude; those papers signed by him bear witness for themselves; in the numerous shorter contributions for which the reader will silently thank the editor the same carefulness and conscientiousness are displayed with the same gratifying result. The "Dictionary of Medicine," indeed, is a worthy monument of untiring energy, of well-spent labour, and of invaluable research and knowledge.

The necessities of publication have demanded compression of the work by resort to double columns and comparatively small type. The inconveniences thus entailed would be remedied somewhat by division of the huge single volume in future editions into at least two "sizeable" books. Otherwise the "Dictionary" is well produced, the printing is beautifully clear, and the paper excellent.

Since this notice was written, a second edition of the "Dictionary" has been published. The suggestion contained above has apparently occurred to Dr. Quain, for the work is now obtainable either in one or two volumes.

ST THOMAS'S HOSPITAL REPORTS. (a)

[SECOND NOTICE.]

DR. JOHN HARLEY has some very uncommon ideas regarding the close connection between constipation and enteric fever. He says: "Constipation is often the forerunner of enteric fever; I believe I may go even further and state that constipation is occasionally the sole cause of enteric fever." This theory, if popularised, would be a source of considerable increase of practice, and therefore of income

to the attending physician. The author is convinced that many an attack of enteric fever has its origin in constipation; and that death from simple idiopathic constipation is a not uncommon event.

Dr. Harley quotes at some length a case of faecal accumulation in the cæcum, and after stating the points of resemblance and difference between it and a case of enteric fever, he sums up as follows:—"Thus, between two groups of symptoms—the one produced by faecal accumulation and obstruction, and the other by the cause of enteric fever—we fail to find any essential distinction." This conclusion is arrived at by comparing the resemblances and differences in the two cases.

The points of resemblance as stated by him are—1. Disgust of a bad odour; 2. Long continuance of the symptoms; 3. Development of a rose rash.

The differences are—1. Constipation; 2. Perspiration; 3. Temperature.

These differences Dr. Harley speedily disposes of. Constipation, he says, is a very common event in enteric fever. Perspiration, though not common, has occurred in enteric fever in his practice. The normal temperature, he maintains, is sometimes seen in enteric fever, and besides, if the faecal matter had been allowed to remain undisturbed in the intestine for some days longer, severe febrile symptoms would no doubt have been developed.

Dr. J. S. Bristowe relates, most candidly, some mistakes in diagnosis of tumours of the abdomen. Three of these were undoubtedly hydatid cysts, and it was assumed that the other two were of the same nature. Two of the large cysts were successfully punctured. The third large tumour was about to be tapped when it was found that it altered its character under manipulation; it became less and less distinct until—though dullness on percussion still remained—it was decided to defer the operation to a future occasion. It transpired that the patient was in the family-way, and examination with a stethoscope revealed the pulsations of the foetal heart. It is true, says Dr. Bristowe, that "no harm was done, but it is quite clear that I was on the verge of doing harm."

In the second case hydatids were mistaken for abdominal cancer. In the third, hydatids were diagnosed in a case of parovarian dropsy. There is not a truer saying, nor one more applicable to our profession, than that we obtain our knowledge by our mistakes, and the mistakes of others, when so candidly laid before us, are the best calculated to prevent their occurrence in ourselves. Honour is as much, if not more, due to those who have the courage to acknowledge and make known their errors, as to those who only relate brilliant and correct diagnoses.

Surgeon H. G. Armstrong gives the result of nerve-stretching in a case of spinal meningitis. The conditions present were very severe lightning pains, confined principally to the legs and lower parts of the body, though occasionally felt in the upper extremities, and aggravated by any change in the weather; tetanic spasms, produced by pressure on the skin, over the coccyx; inability to walk; entire loss of patella tendon reflex; and complete anaesthesia of both lower extremities up to the groins. Sexual power lost, but not desire.

The operation was performed without the administration of an anaesthetic, and was painless. The left sciatic nerve was exposed and stretched.

On the 29th day the patient was free from pain, dressed, and sitting up, and with very slight assistance could walk round the room. Three months after the operation he walked a distance of seven miles before breakfast without fatigue. The result of the nerve stretching has been the recovery of cutaneous sensibility, an almost complete relief from the severe pains and tetanic spasms. The writer considers that this result from operation on one sciatic nerve shows that the stretching acts, not on the periphery, but on the nerve centre.

During the next three months, however, a return of symptoms appeared, and Mr. Armstrong says, "the patient seems to be relapsing into his old condition."

The above contribution, we observe, is not written by a member of the staff, but by the assistant surgeon to the Royal Berkshire Hospital.

The matter contained in the volume, as a whole, is a feeble production for such a large and well-officed establishment as St. Thomas's Hospital.

Correspondence.

THE IRISH COLLEGE OF SURGEONS AND NIGHT LECTURING.

THE following letter appears in the Dublin newspapers last week :—

SIR,—Some persons have violated the understood and expressed wish of the College and its immemorial custom in furnishing to the press a statement of the proceedings of the Fellows on the 4th inst., which is not only untrue in fact, but evidently made public with the intention of prejudicing, by a garbled report, the cause of honesty of medical teaching, with which I have been specially associated, and at the same time lowering me in public estimation.

This report states that "Professor Jacob's motion that the College should cease to recognise night lectures was supported by (certain gentlemen named), and was ultimately negatived by a large majority." Sir, it is untrue that any motion forbidding night lectures was offered by me or anyone else to the College, and equally untrue that my motion was supported by the Fellows named, except by silent vote. My motion was as follows :—

"That this College approves of the determination evinced by the Council to ensure *bond fides* of attendance on courses of medical study, but is of opinion that attendance purporting to be given by persons who are engaged during the usual hours of medical study in other engrossing avocations is not a *bond fide* fulfilment of the four years of study required by the General Medical Council, and therefore ought not to be recognised by this College as sufficient qualification for the Letters Testimonial of this College."

You will observe that this resolution simply declared that medical studies supposed to be pursued by students engaged all day in offices and shops are not what the College or Medical Council mean by *bond fide* medical study.

To this resolution the representatives of night lecturing did not venture to offer a negative, but sought to shelve it by acknowledging its principle, and remitting the subject to the Council.

To it the following amendment was moved by a distinguished Fellow—one of the staunchest opponents of night lecturing and all other methods of evading study :—

"That the College, instead of passing any order at the present meeting regarding night lectures, request the incoming Council to forward a copy of the arrangements for securing the attendance of students at lectures and hospital to every lecturer and clinical teacher recognised by the Council with a request that they will aid in carrying out these arrangements."

The sense of this amendment is that the College should take no ulterior steps until it had fully tried the efficacy of the regulation to ensure *bond fides* of study which it promulgated last year. I could willingly have voted for this amendment if I had any faith that the "request" of the College will have effect with the teachers who are parties to the evasion. Failing that hope, I felt it necessary to divide the College on the amendment, with the result that the Fellows, by a majority of 28 to 16, decided to wait, and hope for an honest fulfilment of the Collegiate regulations.

This was a decision in no sense favourable to night lecturing or sham study. This time next year we shall know whether the trust of the Fellows has been misplaced, and, if it shall appear that it has, I shall certainly—if possible—renew the effort to put a stop to sham medical education in Ireland.

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB, M.D., F.R.C.S.I.

Obituary.

MR. BENJAMIN BELL, F.R.C.S.ED., M.R.C.S.ENG., OF EDINBURGH.

THIS well-known and respected Edinburgh surgeon has just passed away, at the age of 73. His illness, which terminated fatally, originated in a severe cold, which developed into inflammation of the lungs, and suffering at the time from impaired vital energy and depression owing to the recent loss of his wife, to whom he was greatly attached, he had not strength

to combat the attack referred to, and death ensued on Friday last.

Following the footsteps of his grandfather and father, who were previously surgeons of considerable eminence, the subject of this notice very early in his career showed signs of high talent and future eminence. He rapidly acquired an extensive practice, principally in eye surgery, and soon became one of the most popular surgeons in Edinburgh. In 1835 he was elected a Fellow of the Royal College of Surgeons, and has ever since taken an active interest in the work of the corporation, frequently acting as examiner. Among other bodies with which he became connected were the Edinburgh and St. Bartholomew, the Royal Medical and Medico-Chirurgical Societies, Edinburgh; the Surgical Eye Infirmary, Edinburgh; George Watson's Hospital, and the Asylum for the Blind, Edinburgh. He was also surgeon to the Royal Public Dispensary, and in 1863 an examiner in medicine in the University of Edinburgh, and in 1864 he was elected President of the Royal College of Surgeons, Edinburgh.

Mr. Bell contributed some able papers to various medical journals, among the more important being one on "Cerebral Diseases," which appeared in the *Edinburgh Medical Journal* for 1847, and another, "On the Outbreak of Scarlet Fever in George Watson's Hospital," published in 1851. Besides being well known in his profession, Mr. Bell enjoyed a widespread popularity as a public citizen. He took a deep and lively interest in most of the public questions of the day. His well-known presence will be missed at many a public meeting. His character displayed a happy combination of simplicity and amiability, on the one hand, with a readiness, on the other, to look at new views for himself, and to hold and express his own opinions with firmness. He took a deep interest in every form of mission work, and was largely instrumental in establishing the Edinburgh Medical Mission, and in furthering the training of medical missionaries for foreign service. Mr. Bell is survived by a family of five sons and three daughters, his eldest son, Mr. Joseph Bell, F.R.C.S.E., now practising in Edinburgh, being the only member who has followed the medical profession.

PASS LISTS.

Royal College of Surgeons of England.—The following Members having passed the required examination for the Fellowship, were admitted Fellows of the College at a meeting of the Council held on Thursday, June 14th :—

- Collingwood, David, M.B. Lond., Bedford Street, Liverpool.
- Duncan, W. Archdeacon, L.R.C.P. Lond., Lambeth Palace Road.
- Elam, William Henry, Mirfield, Yorkshire.
- Gross, Charles, L.R.C.P. Lond., Watworth.
- Horseley, V. A. Haden, M.B. Lond., Gower Street.
- Wainwright, Benjamin, M.B. Edin., Belmont, Lee, was admitted to the Fellowship, though not a Member.

Two other candidates passed the examination, but being under the legal age (twenty-five years) will receive their diplomas at a future meeting of the Council. Ten candidates failed to reach the required standard, and were referred for twelve months' further professional study.

College of Physicians in Ireland.—At the June examinations the following candidates obtained the licences in Medicine and Midwifery of the College :—

Notices to Correspondents.

DR. J. KINGSTON FOWLER will give a Clinical Demonstration at the Brompton Consumption Hospital to-day at 4 p.m., "On some Points in the Diagnosis, Prognosis, and Treatment of Thoracic Aneurism." Members of the profession admitted on presentation of their cards.

PROFESSOR HUTCHINSON'S LECTURES AT THE LONDON COLLEGE OF SURGEONS.

IN accordance with our annual custom, we propose presenting our readers with the complete course of lectures now being delivered at the Royal College of Surgeons of England by Professor Jonathan Hutchinson. The subject selected is "Diseases of the Tongue," the first lecture of which will be commenced with the new volume of the *Medical Press* on July 4th.

DR. C. THEODORE WILLIAMS' lectures "On the Relation of the Tubercle Bacillus to Phthisis" will be commenced in our next.

WE hope to recommence the papers "On some Implications of Dissolution of the Nervous System," by Dr. Hughlings-Jackson, F.R.S., in the first number of the new volume in July.

DR. BERNARD KELLY.—The addition shall be made in due course, and proof sent you before insertion.

DR. ROGERS is thanked for his efforts on behalf of "A Retired Poor-law Medical Officer," to whom a miserable board of guardians refused superannuation, after nearly half-a-century's faithful services, on the plea of not taxing the ratepayers. We hope to enlist further sympathy in the case, and expect the matter brought before the House of Commons in the course of a few days.

SANITARY ASSURANCE.

AT a meeting of the Council of the Sanitary Assurance Association, held on Monday, June 11th, Sir Joseph Fayrer, F.R.S., in the chair, the following resolution, recently passed by a meeting at 9 Conduit Street, W., was considered, viz.—"That the Council of the Association be requested to consider whether they cannot recommend legislation compelling the builders of all new dwellings to obtain a certificate from some authority or qualified person as to their sanitary condition before it shall be lawful for such buildings to be inhabited." On the motion of Professor Hayter Lewis, F.R.S., seconded by Professor Corfield, M.D., a sub-committee was appointed to consider how best the object of the resolution may be attained, and, if desirable, to draft a Bill and report to the Council.

CORRECTION.—Owing to an unfortunate combination of printer's error with want of revision, Dr. Cory was, in our last issue, credited with holding very remarkable opinions on syphilis. It is hardly necessary to explain that the statement made was not that intended; but the note having been printed without first being read, the important omission of words to the effect that Dr. Cory did not believe in inoculation of true syphilis *via* lymph, was allowed to pass unnoticed, with the result referred to. Obvious though it is, the blunder demands this explanation.

MR. SIMMON.—The labour was most unnecessarily bestowed. There are at least a dozen books in which the whole particulars are given as fully and completely as you have been able to give them. For any purpose of information your results are no more valuable than these, and it could advantage no one if we were to publish them. The report is of a different degree of value, and is accepted with thanks.

MR. CRANSTON.—It is very unlikely that any distinction would be intentionally made by an examiner; it is much more probable that you are altogether mistaken in the matter, and that the suggestion made to you was without any justification in fact. This interpretation is, at any rate, the wisest one you can put on the occurrence.

R. T.—We hope to publish a complete account of the experiments at an early date.

A WORKING SURGEON.—Tenotomy knives will be found most useful for the purpose. If carefully performed, the operation should not be attended with serious risk. Antiseptic dressings should be employed, but the spray need not of necessity be used.

ANOTHER UNQUALIFIED ASSISTANT.—The blame is less yours than your employer's, but you alone will be held responsible in the event of proceedings being instituted. 2. We do not think so.

X. Y. Z.—See Vol. XIII. of the *Clinical Society's Transactions*.

MR. HORNBLLOWER.—It is a matter of custom, and usage varies in this respect in different places. You can easily ascertain the terms made with your predecessor, and may very well be guided in the course you elect to pursue by the information thus obtained. It is not a question of law.

M. A. F.—Several successful cases of transfusion of saline fluid have recently been recorded. You should make yourself acquainted with them first.

THE POWERS OF COMMITTEES AS TO LOCUM TENENS.

NEMO asks: Is it compulsory on a dispensary committee to accept the nominee of their officer, who is incapacitated through illness? or is it competent for them to appoint any person they choose, provided he is duly qualified, to act as *locum tenens*?

[The committee may do exactly as it pleases in the matter; the medical officer is simply to recommend some person who possesses the legal qualifications to be a *locum tenens*. Any such person will do, and it is not the business of the medical officer to negotiate with him, or ascertain his willingness to act, nor to pay him a farthing for his services. All these are the functions of the committee, and they may accept the person recommended, or appoint any other person at their discretion.—ED.]

MR. JAS. STURTIN (St. John's Hospital for Skin Diseases).—We fail to see that you are even remotely referred to in the annotation; "the management" only is mentioned, and we understand that you have no control over, or voice in this.

A CHRONIC (Bath).—We do not prescribe in these columns, but would advise our correspondent to purchase the little book just issued from the pens of Professor Titchborne and Dr. Prosser James, "On the Mineral Waters of Europe;" he will there see the composition and therapeutical value of all the known waters, and will gain some hints as to their suitability in his case.

DR. W. J. C.—We do not see that you are responsible for an indiscretion of your partner. He should frankly apologise to his neighbour and thus avoid the threatened professional scandal.

DR. T. T. P.—Thanks for the lines, which contain a good many truisms, but as our province is medical journalism, we are unable to accept them for publication, religious topics being more appropriately discussed elsewhere. The paragraph about "Pseudo-medical Degrees" has already appeared in our columns, and has often been quoted elsewhere.

MR. FORBES (Chelmsford).—The author will doubtless be glad of the correction, which, though of one word only, is of considerable moment. We will forward your letter to him.

PROFESSOR JONATHAN HUTCHINSON, F.R.C.S., will deliver a course of lectures at the Royal College of Surgeons of London to-day (Wednesday), Friday, June 22, and on Monday, Wednesday, and Friday next week at 4 p.m. Members of the profession will be admitted on presentation of their cards.

Appointments.

- BLAIR, E. M.D., C.M. Glas., Medical Superintendent to the Lunatic Asylum to the Barony Parish of Glasgow.
 BROWN, J. M., F.R.C.S. Eng., M.B., M.C. Ed., Surgeon to Out-patients to the North-West London Hospital.
 BURNET, E. W., M.D., C.M., Pathologist to the Chelsea Hospital for Women.
 DICKINSON, T. V. M.D. Lond., Assistant Physician to the Chelsea Hospital for Women.
 DONNELLAN, F., L.R.C.S.I., Medical Officer for the Wexford Union.
 HARRIS, J., M.D. Lond., Resident Medical Officer to the Chelsea Hospital for Women.
 HORROCKS, P., M.D. Lond., B.Sc., Assistant Physician to the Chelsea Hospital for Women.
 LINTON-JONES, W. H., Anesthetist to the Chelsea Hospital for Women.
 MACKENZIE, J., B.A., M.B. Cantab., Assistant Physician to the Chelsea Hospital for Women.
 RODLEY, J., L.R.C.P. Ed., M.R.C.S., House Surgeon to the Bucks General Infirmary.
 ROOPOFF, W. M., M.R.C.S., L.R.C.P. Ed., Honorary Medical Officer to the Royal Albert Edward Infirmary, Wigan.
 SAINSBURY, H., M.D. Lond., M.B.C.P., Physician to Out-patients to the North-West London Hospital.
 TRAVERS, W., M.D., Assistant Physician to the Chelsea Hospital for Women.
 VENN, J., M.D., M.R.C.P., Assistant Physician for Diseases of Women to the West London Hospital.
 VALENTINE, E. W., M.R.C.S., Medical Officer for the Second District of the Langport Union.
 VOS, G. H., B.A. Cantab., M.R.C.S., House-Surgeon to the Training Hospital, Tottenham.
 WALKER, T. S., M.R.C.S., Hon. Consulting Ophthalmic Surgeon to the Royal Albert Edward Infirmary, Wigan.
 WARREN, F. W., M.B. Dub., M.K.Q.C.F.I., F.R.C.S.I., Surgeon to the Adelaide Hospital, Dublin.
 WESTBROOK, E., L.R.C.P., L.R.C.S., Assistant House-Surgeon to the Poplar Hospital.
 WILLIAMS, E., M.R.C.S., L.R.C.P. Ed., Honorary Ophthalmic Surgeon to the Royal Albert Edward Infirmary, Wigan.
 WILLIAMS, W. T., M.R.C.S., Second Assistant Resident Medical Officer to the Birmingham Workhouse Infirmary.

Vacancies.

- Brompton Consumption Hospital.—Resident Clinical Assistant. Further particulars to be obtained of the Secretary (see Advt.).
 St. Mary's Hospital, Paddington.—Demonstrator of Physiology. Value of appointment, £100 per annum. Applications to the Dean before July 7th.
 Bath, Eastern Dispensary.—Resident Medical Officer. Salary, £100, with extras. Applications to the Hon. Sec. before July 2nd.
 Stockton-on-Tees Hospital.—House Surgeon, non-resident. Salary, £200. Applications to the Secretary before July 14th.
 Rochester District Friendly Societies' Association.—Resident Medical Officer. Salary, £200, with extra fees and house. Applications to H. T. Kybett, 50 High Street, Chatham, Kent, on or before June 2nd.
 Royal Hants County Hospital, Winchester.—House Surgeon. Salary, £100, with board. Applications to the Secretary before July 4th.

Births.

- HATCHELL.—June 13, at Maryborough, Queen's County, the wife of Dr. J. H. Hatchell, of a son.
 KINKAD.—June 12, at West House, Galway, the wife of R. J. Kinkad, M.D., of a son.
 STACK.—June 12, at 12 Idrome Terrace, Blackrock, the wife of R. Theodore Stack, M.D., of a daughter.

Deaths.

- NELSON.—June 14, at 12 The Circus, Greenwich, suddenly, Thomas Nelson, M.D., R.N., Inspector-General of Hospitals, aged 65.
 SHORTHOUSE.—June 12, at his residence, Croxteth, Joseph Henry Shorthouse, M.D., LL.D., after a protracted illness.

IRISH POOR-LAW INTELLIGENCE.

DISMISSAL OF UNION OFFICERS BY BOARDS OF GUARDIANS.

THE following additional correspondence, which closes the subject for the present, has taken place between the Council of the Irish Medical Association and the Irish Local Government Board :—

LISMORE UNION.

(Copy).

Local Government Board,
Dublin, 7th November, 1882.

SIR,—The Local Government Board for Ireland have had under consideration your letter of the 26th ult. respecting the recent resignation by Dr. O'Reilly of his appointment as medical officer of the workhouse of Lismore Union, and the Board desire for the information of the Irish Medical Association that the vacancy created by Dr. O'Reilly's resignation has been filled up by the guardians, and the Board do not consider it necessary to enter into a correspondence on the subject. With reference to the request of the Council that the Local Government Board will take steps for the reinstating of Dr. O'Reilly in the office which he held, the Board desire to point out that when a medical officer's appointment becomes vacant by resignation or otherwise, it can only be filled by an election conducted in the manner prescribed by the general regulations.

By order of the Board,

(Signed) W. D. WODSWORTH.
Assistant Secretary.

To Wm. Thomson, Esq., M.D., &c.

Irish Medical Association,
December 8, 1882.

SIR,—I am directed by the Council of the Irish Medical Association to state, in reply to your letter of 7th Nov., "No. 32,679 Lismore Union," that, in view of the circumstances that the office vacated by Dr. O'Reilly has already been filled by the appointment of another medical practitioner, the Council will not continue to urge the reinstatement of that gentleman.

The Council desire to remind the Local Government Board that Dr. O'Reilly's resignation of office was not a voluntary act, but that he was forced, notwithstanding his repeated protests and appeals for full investigation of the circumstances, to vacate his appointment in consequence of the unjust, and—as the Council believes—illegal course adopted by the Board of Guardians, not only with the concurrence, but apparently at the suggestion of the Local Government Board for Ireland. The Council hold the opinion that suspension of an officer

from the performance of his duty is a power entrusted to Boards of Guardians solely, in order that they may be enabled, in case of emergency, to dispense temporarily with the services of an officer pending the immediate investigation of some serious charge, which would, if proved, render him unfit to continue in office, and with a view to his reinstatement if the accusation were not established. To use such a power for the purpose of permanently removing an officer against whom no such charge has been made or sustained is, in the opinion of the Council, an abuse of the law, inasmuch as it is an assumption by the Board of Guardians of the power of dismissal, which is the prerogative only of the Local Government Board, and is exercised by them subject to the approval of Parliament.

The Council of the Irish Medical Association apprehend that by the course which has been pursued towards Dr. O'Reilly, a precedent may be established which it would be their duty to contest, as they believe that course to be altogether illegal and contrary to the intention of Parliament, and as the establishment of such a precedent would obviously be most prejudicial to the status of Poor-law medical officers.

In this instance, Dr. O'Reilly's resignation appears to preclude the Council from bringing the case into court and obtaining a judicial decision on the subject; nevertheless, the Council desire to state emphatically their opinion that, so long as the State compulsorily imposes upon Poor-law medical officers duties, the proper discharge of which tends to bring them into variance, if not conflict, with Poor-law guardians it is essential to the efficiency of the service that the position of those officers shall be rendered as independent as possible, and that they shall receive at the hands of the Local Government Board the utmost consideration and protection in the due performance of their duties. Were it not that Boards of Guardians are aware of the powers conferred by the Legislature on the Local Government Board to protect their officers against harsh and unjust treatment, a considerable number of those officers would doubtless find it impossible to discharge their duties efficiently and conscientiously. The Council therefore expect that the Local Government Board will afford to Poor-law officers the protection necessary for the performance of their functions, and not afford its countenance to unscrupulous attacks, nor visit with punishment any complaints until it has, by a thorough and independent investigation, fully satisfied itself that the case is one which really merits the punishment meted out. In the case in question the Council regret to think that no adequate investigation was held by the Local Government Board. The Council therefore feel, that they have no other course open to them than to reiterate emphatically their protest against the compulsory removal of Dr. O'Reilly from office at the caprice of the Board of Guardians, and, without any

to reach the lung by inhalation, to develop in the alveolar epithelium, causing it to proliferate through irritation. The alveolus becomes stuffed with cells which either caseate at once, or, if the process be a slow one, are partly converted into giant cells. Infection of neighbouring alveoli takes place either by continuity or by inhalation of bacilli from other parts. The further progress depends on the rate of bacillus multiplication, or on the fitness of the soil for their development. If they multiply quickly caseous pneumonia and rapid lung excavation ensue; if slowly, the resulting caseation may cause thickening of the alveolar walls with inflammatory tissue, and further infection be prevented by this fibrous barrier, this taking place in fibroid phthisis. When the lungs become largely involved, the walls of the pulmonary veins are attacked, and bacilli entering the circulation, give rise to acute tuberculosis. According to Weigert, they may enter the innominate veins from the bronchial glands, and Koch gives an instance where a bronchial gland gave rise to disease in an artery of the lung, and thus infected the system.

The bacillus theory explains the limited portion of the lungs attacked in early phthisis, the spread of tubercle around cavities or caseating centres, and the infection of the opposite lung by inhalation of the sputum; also the spread of disease by the lymphatics and blood-vessels; it also explains the limitation to the lungs of galloping consumption, of tuberculo-pneumonic phthisis, and of catarrhal phthisis, but it does not elucidate the thoroughly constitutional features of scrofulous phthisis or the origin of hæmorrhagic phthisis, or the comparative freedom of the larynx and trachea from caseation and ulceration in spite of the bacillus-laden sputum passing over them.

The lecturer discussed the question of fitness or unfitness of soil for the reception of the bacillus, in which the key of the position must be sought, as, considering the prevalence of consumption, there is little doubt the bacilli must enter the air passages of healthy people without harmful results. He stated that the various well-known predisposing causes of consumption, such as dampness of soil, bad ventilation, miscarriages and confinements, and other debilitating conditions, might act by preparing a fit soil, either by giving rise to low inflammatory conditions which tend to cellular products, or by weakening the resisting powers of the constitution. The recognition of one exciting cause, instead of many, may lead not only to direct remedial measures against the same, but equally and perhaps more effectually to combat the predisposing causes.

The tubercle bacillus varies in length from 1-3000th to 1-12000th of an inch, its breadth being as a rule uniform, about 1-5th of an inch (Heron), though the older ones appear somewhat broader than those which are less developed. Some are only twice as long as they are broad; others extend over 1-12th of the microscopic field; some are straight, with slightly rounded extremities; others are curved, and occasionally have a vermiform appearance. They are found singly or in groups, in the latter case, sometimes appearing like bundles of sticks, 3, 4, and 5 together. This grouping seems to indicate activity of disease. They can be seen from 4-10th inch power upwards, but are clearest under powers ranging from 1000 upwards. Each rod when well developed shows a number of beadings, from 4 to 8, or even more, and these separate from each other and are called the spores, from which fresh bacilli grow. Mr. Cheyne describes an external membrane enveloping the beaded rod which stains with the same dye. The bacilli have been found by the lecturer to increase in sputum after long keeping in a warm atmosphere: he suggests that this may be one of the causes of their accumulation in the cavities of advanced cases of consumption, where expectoration is difficult.

The practical value of the bacillus in aid to diagnosis was then considered, and it was shown by illustrative cases to assist in separating chronic pneumonia and bronchiectasis from phthisis, and in throwing light on

incipient laryngeal phthisis and catarrhal phthisis, in the former there being often difficulties of diagnosis from the swelling of the mucous membrane of the larynx rendering the act of respiration painful, and thus interfering with satisfactory auscultation. In the latter the sonorous rhonchus and sibilant râles often mark tubercular consolidations, the nature of which examination of the sputum now reveals.

Still, Dr. Williams urged that, however valuable this test is in the above classes of cases, it must never be allowed to interfere with most careful physical examination of the chest, as, after all, the presence of bacilli cannot define the locality, or even the extent of the diseased area, but can only indicate the existence of the tubercular process.

NOTE UPON A READY METHOD OF TESTING THE PURITY OF MILK.

By F. J. B. QUINLAN, M.D., M.R.I.A.

A QUICK, simple, and reasonably accurate mode of accomplishing the above object has long been a desideratum to public institutions, and even to private families, but the want can hardly be said to have been supplied. The favourite domestic method of testing milk is the upright cylindrical glass tube, the upper fifth of which is graduated in hundredths; so that, when the milk sets, the percentage of cream can be read off. But this is not an immediate plan. The other resort, the float, is wholly unreliable, inasmuch as the addition of gummy or saccharine compounds will run up the specific gravity of very poor milk.

I would wish to briefly describe the Milchprüfer (milk tester) of Heeren, which is at once quick, simple, and accurate. It consists of a circular disc of black vulcanite, 2½ inches in diameter, in the centre of which is a cup 8-10ths of an inch in diameter and 1-50th of an inch in depth, the bottom, of course, being black. If this cup be filled with a few drops of milk, and a perfectly flat cover glass laid on it, a stratum of milk of a constant thickness will be secured, and will have a colour varying according to its dilution, from the white of cream to the bluish shade of milk which has been conscientiously skimmed and then liberally watered. The second part of the instrument is a circular piece of very thin plate glass of the same size as the disc, and which is lined with coloured vulcanite (like the silvering of a mirror), except in the central part corresponding to the cup. This annular vulcanite lining is divided into six equal radial segments, presenting an harmonious series of colours from cream to bluish, and labelled respectively "cream," "very fat," "normal," "less fat," "poor," "very poor."

In using it the observer stirs the milk with a spoon to make it homogeneous; and then, letting a few drops into the cup, lays on the cover-glass disc, taking care that there shall be no air bubbles. The eye will at once determine that the stratum of the milk being tested corresponds in colour to some one of the radial segments, or is between two of them. I have tried with it a specimen of milk enriched with cream, so as to correspond with No. 1; and by successive additions of water brought the specimen to correspond with each number of the scale; and, thus tried, the instrument showed great accuracy. It is manufactured on a large scale by the Hanover Vulcanite Company, and is inexpensive.

PROFESSOR GRAINGER STEWART, OF EDINBURGH. — It affords us much pleasure to congratulate Prof. Grainger Stewart on his return, after an enforced absence abroad in search of health. This, we are glad to hear, he has attained after his severe illness in the winter; and when, for the first time, he presented himself to his class at the University on Saturday last, he received a hearty ovation.

duty as a medical man. It was, counsel added, comforting to Dr. Sparrow, when such an unfounded charge was made against him, to find himself surrounded and supported by his honourable colleagues, as he was that day. One of the risks of the noble profession of medicine was to have false charges made against physicians by hysterical and designing female patients. Such a charge, only the other day in England, cost an innocent man his life. Dr. Sparrow then left the court, accompanied by his friends.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

(Continued).

Dr. JACOB'S examination continued.

898. You stated also your reading of the law, and I have no doubt your reading of the law is correct, because I am sure, from your experience, and from the evident care you have given to the matter before this Committee, you would not advance anything of which you were not certain; but you say, as to the practice of a medical man resigning before he can claim superannuation, that that is not usually so; that the dispensary doctor is at liberty to inform the board of guardians or the dispensary committee, of his desire to resign, and he need not so resign until he makes his ground sure?—Under the Act of Parliament I believe that that is so. I know of one case in which the medical did not resign, but simply notified his intention to resign, and the board of guardians nevertheless did consider his pension, and did grant him a pension on the day that he retired, and therefore there can be nothing illegal in the practice of a medical officer withholding his resignation up to the day when his case is considered.

899. Do not understand me as assuming that there is any illegality, but I am glad to get your information upon the subject, and the information is new to me, and I accept it as accurate; as regards the other reasons that you give for this Bill, one was that concurrently with the position held by the dispensary doctor he has private practice more or less?—Yes.

900. Experience has shown that in towns or aggregations of communities as a man's private practice grows and becomes of larger importance, he surrenders the dispensary?—Yes.

901. And you give it as one of the advantages of this Bill that, if a man had a limited private practice, and under the established state of things he had given in his resignation, and his resignation had been accepted without a pension, that then there was the danger of a rival practitioner coming in?—Yes.

902. Does it always occur that a rival practitioner comes in?—Not with the advantage of an official position behind his back; if A., being a practitioner in a district, deserts his offices and leaves it open to B., B. would set up against him as a rival practitioner under exceptionally favourable circumstances; therefore, my contention, is that there is no danger of abuse of the Act, inasmuch as A. will not leave his official position until the very last moment that he is obliged to do so.

903. I do not like to ask you any question that may injure the *esprit de corps* of your profession, or hurt your feelings in any way, but is it true, as a matter of fact, that a great many dispensary physicians in Ireland hold on to their situations pledged to the performance of certain duties, conscious that they are incompetent and unable to perform them, simply on account of the question of superannuation?—Yes, certainly, it is the fact.

904. You stated that one of the reasons why the dis-

pensary doctor, or resident medical doctor of the union, was not likely to have his claim for superannuation fairly considered was, that there might exist between him and the majority of the board political and religious differences?—Yes.

905. And you also stated that it might arise from his brusqueness of manner?—Yes.

906. Will you give me leave to ask you, is not a doctor always, in the first instance, elected either by the members of the board for the position of resident medical officer, or by the members of the dispensary committee for the dispensaries themselves?—Yes, always.

907. Therefore, as elected originally, there were no political or religious difficulties; if he was a favourite of the electors, presumably he would have neither political nor religious difficulties with the members of the board?—At the time he was elected thirty years ago he was presumably of the same colour as his elective board.

908. Then it follows that to establish your ground for there being political and religious difficulties, either the board must have changed its constitution, or the doctor must have changed his political and religious opinions?—Not strictly speaking, because you must recollect that the question of superannuation of a medical officer comes before the board of guardians, whereas his election comes before the dispensary committee, which may be of an entirely different political and religious line. A man of their religion and politics may be elected by the dispensary committee; but when he comes for his pension he has to go before a different tribunal.

909. In that answer you assume that the dispensary committee is not a reflex of the board?—There may be such instances.

911. The average salary of a doctor, that is to say, his salary alone, I understand you to say, amounts to £102 per annum?—Yes, roughly speaking.

912. You were asked by the honourable Member for Wexford whether the emoluments received from a number of offices under the Public Health Act, the registration of births, deaths, and marriages, add an average increment of £30 a year?—Yes.

913. Then, in effect, the average income of those gentlemen who come to have their cases considered by the Committee is £130 per annum?—Yes.

914. And that £130 per annum is quite independent of means which may accrue to them from their private practice?—Yes; but the average in these sort of matters is entirely deceptive, and the persons who would be getting that pension would be likely to be men whose incomes had been excessively small from private practice, and therefore the average ought not to be made to apply to them; but if you ask me what the average is it is what I stated.

915. Is there any instance within your own knowledge of dispensary doctors receiving superannuation, they themselves being in receipt of an income from means acquired in the practice of their profession?—Yes.

916. Then as regards the refusal by the board of guardians to fairly consider the claims of the doctors, that is modified by the fact that they have given superannuation allowances to men whom they knew were in the receipt of incomes independent of the superannuation allowance?—Certainly.

917. Does that prevail to a fairly large extent?—Yes, it does; a good number of the persons who have been superannuated are persons who have more or less private practice.

918. There is this important distinction between the doctors and some other persons employed by the Poor-law Board, that the doctors have not given their whole time, except the resident officers in unions, and a great many other servants of the Poor-law Board have devoted their

whole time?—Doctors are obliged to place the whole of their time at the disposal of the guardians; no portion of their time of the whole 24 hours is free to themselves; every minute they are liable to be called upon, and they must, to the exclusion of every other sort of business, attend to their union duties; but, on the other hand, they are not whole time officers in the sense that they may engage in private practice.

919. And, in point of fact, very many of them enjoy large means from private practice concurrently with their holding the office of dispensary doctors?—Yes, they could not live upon the salary they get.

926. Capt. Aylmer: Do you think that, as a general rule, medical officers who have a qualifying service for superannuation will retire when they arrive at 68 years of age?—I certainly do not think so.

927. You think that they would continue on, having a practice in the place?—A great number will continue on as long as they can possibly get along sooner than introduce another practitioner into the district.

928. If this Bill passes, is it not possible that boards of guardians may, if pressure is put upon them by aspirants to the post, make them take their superannuation as soon as they arrive at 60 years of age?—Generally speaking, a medical officer is sufficiently well lodged in the place to prevent aspirants ousting him in that way; I would not apprehend that.

Mr. ROBERT STEWART, *called in, and examined.*

985. Chairman: I believe you are a guardian of the Belfast Union?—Yes.

986. How long have you been a guardian?—For two or three years.

988. Are you in favour of that Bill?—In many of its issues I am opposed to it.

990. Do you think that any change is necessary in the existing system of pensioning Poor-law officers in Ireland?—I do not.

991. What has been your practice in reference to pensions in your union?—In the Belfast Union there have been no pensions granted for about seven years so far as I know.

995. Therefore a union officer in the Belfast Union could have had no reasonable expectation that he would be sure of receiving a pension when he retired?—He could not by any means be sure.

996. That may have accounted, in your opinion, for the fact that they did not stay long in that union?—Yes.

997. Can you account for it in any other way?—The resident officials, the chief officials, were not sufficiently well conducted throughout to entitle them to pensions.

999. Was not it possible for the board of guardians to make sure when they engaged their officers that they were efficient men?—That is sometimes largely the result of chance or accident.

1000. I understand you to say that at present you do not take the granting of any pension into consideration?—I do not, especially in the case of dispensary and medical officers: I am entirely opposed to it.

1001. During the last three years, do you find that your officers have held on for longer periods in the employment of your union?—I do, but I do not think it arises out of any particular hope with regard to pensions.

1002. On the other hand, should you say that the knowledge that they will not receive pensions induces them to retire at an earlier age than they would retire if they thought they were going to receive pensions?—I have never known of any resignations connected with the question of pensions; in fact, the chief cause of their leaving our employment at all was generally dismissal, or compulsory resignation.

1003. Are there any old officers in your union?—The oldest officer has been eight years in our employment at present.

1004. What is his age?—I suppose about 53.

1011. Chairman: Have any officers in your union resigned from infirmity?—There has not been one that I am aware of.

1012. In regard to the Bill before the Committee, do you think it is advisable that in some unions boards of guardians should go on the principle of granting no pensions, and that in other unions they should go upon the principle of granting pensions to all, and that in many unions they should go upon no definite principle in giving pensions?—I think the law as it stands is sufficiently good to meet the whole case; that is to say, that if persons really merit pensions, then let the guardians fix the sum that should be granted.

1013. By your own showing you say that some change in the existing system is necessary for this reason, that your union declined to grant any pensions at all?—No, I did not say that.

1014. They have not granted any?—They have granted pensions on two occasions.

1015. In the last seven years they have not granted a pension, as I understand you?—They granted a pension seven years ago, or recommended it, but it was unconfirmed by the Local Government Board.

1016. I understand you to say that you have made it a practice not to grant pensions from that time?—They never were asked; so far as I am aware, no application has come before the Board for seven years.

1017. Did they let the officers know when they took service in your union that pensions were not granted?—They never held out any such inducement or hope; I think the officers were sufficiently well acquainted with the fact.

1018. Your opinion then, as I follow you, is not against giving pensions *in toto*?—I think that the law as it stands is fair enough; that is if the guardians consider the relative merits of the applicant as the case comes before them, it might be a fair enough thing. I believe the guardians should have free control in the matter of granting pensions.

1019. I understand you to say, that the guardians generally in Poor-law unions have done their duty in reference to giving pensions?—I think they have.

1028. Mr. Gibson: Are you of opinion that as a matter of public policy, if a man or woman has served the union faithfully for a great number of years and is worn out in the service, and their service has been blameless and upright, it is right to give them a pension or compel them to go into the workhouse as an inmate?—If their conduct had been blameless, it would be a fair case for consideration, but I am sorry to say that I have not found them blameless.

1029. You must take my question as I put it, and not as you put it. Take my proposition. Supposing a union officer, man or woman, has spent his or her whole life in the service of the ratepayers, say 40 or 50 years, and has arrived at the age of 75 or 80, and that their conduct has been uniformly good and blameless, and that they were worn out in the service, and are no longer able efficiently to discharge their duties, is it desirable in the public interest that a public servant should be pensioned, or compelled to go as an inmate into the workhouse?—It would be a very proper question for the guardians to consider whether they should give him or her a pension.

1030. That is not my question. Do you think it is desirable for the public service, that that person should be given a pension, or compelled to go as an inmate into the workhouse?—Under the circumstances the guardians would be disposed to consider it.

1031. That is not my question. Do you think that it would be just and proper that that person should be given a pension or be compelled to go into the workhouse as an inmate?—The pension in the case of a woman would be so limited, according to the present Bill, that I do not think would be worth the guardians' while to grant it.

(To be continued.)

IRISH POOR-LAW INTELLIGENCE.

THE MEDICAL REFORM CONTROVERSY IN DUBLIN.

At the meeting last week of the Dublin Branch of the British Medical Association an organised effort was made to induce the members of the Branch to throw over the Medical Reform policy which, for many years past, has been advocated both by the British and the Irish Medical Associations, which policy is substantially the same as that adopted by the Royal Commission which sat last year to investigate the subject. A majority of the Council of the Branch has been induced by a no-surrender sub-committee to advise the profession in Ireland to take up the same humiliating position of hostility to improvement which has hitherto been special to Scotland alone. We cannot now enter upon the question further than to express our entire confidence that when the question is fully discussed at the adjourned meeting of the Branch on Tuesday, the 6th, the members of the Association will resolutely refuse to join in opposition to the endeavour to put medico-educational affairs throughout the kingdom on a satisfactory footing. Every member of the Branch is well aware of the loss in public estimation which the profession has sustained from the disreputable traffic in diplomas which the no-surrender committee now seeks to preserve. Every one knows of the trade which has been driven in low-class diplomas by the Scotch corporations, and of the serious injury done to Irish and English licensing bodies thereby. Every one knows that the General Medical Council, after its quarter of a century of probation, has proved itself unwilling and incompetent to check these abuses. We shall therefore be greatly mistaken in our estimate of the spirit of the Dublin practitioners if we find them led to desert the policy adopted years ago by earnest reformers.

GALWAY GUARDIANS.

AN unusually large meeting was held last week for the appointment of two medical officers, one for the Dispensary and the other to the post of Junior Medical Officer to the Union Workhouse. Both positions had been held by the late lamented Dr. Clayton. The candidates for the post of dispensary medical officer were—Dr. Rice, Dr. Kirwan, and Dr. Lyden. The voting was as follows:—For Dr. Rice, 20; for Dr. Lyden, 13; for Dr. Kirwan, 5. The candidates for workhouse medical officership were—Dr. Pye and Dr. Grealy. The voting was—Dr. Grealy, 33; Dr. Pye, 20.

DUNMORE (GALWAY) DISPENSARY.

A MEETING was held last week for the purpose of electing a medical officer for the Dunmore dispensary district, Mr. W. D. Griffith, J.P., in the chair. There were two candidates, who received ten votes each, viz., Dr. O'Reilly, of Lismore, and Dr. Donnellan, of Castlereagh. The election, having resulted in a tie, must be held again, unless one of two votes on Dr. Donnellan's side be disqualified by the Local Government Board, both being objected to.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

Mr. ROBERT STEWART, called in, and examined.

(Continued).

1032. That is not my question. I must ask it again, and it is a plain one. If a union officer, man or woman, has spent his or her whole life in the service of the union, and has become worn out in the service, say 40 or 50 years, and has performed his or her duties honestly and soberly and in a blameless way, is it just and expedient that that public servant should be given a pension, or be compelled to go into the union workhouse as an inmate?—I think if all the circumstances regulating the conduct of that official were as you put them, she would not be entitled to a pension, because she would have saved a sufficient competence to prevent her going into the workhouse.

1033. Then you are against a pension in any case?—I might not be.

1034. I must put the question again. Will you state the case to the Committee where you consider that such a person would be entitled to a pension?—There was a case in which I would have voted for a pension; it was the case of a workhouse master; he was 30 years in the service, and I thought he was harshly treated by the guardians for some very small fault; he was compulsorily forced to resign, and I thought it was a case in which he should have got a pension.

1038. Can you state to the Committee any circumstances where, independently of harsh treatment upon the part of the guardians, you consider any union officers would under any conceivable circumstances be entitled to any pension whatever?—I do not know of any case.

1039. Then you are against the principle of pensions, root and branch. You are of opinion that men and women employed in the union should save out of their earnings to provide for old age?—Practically, that is the fact.

1045. You have been listening to the other evidence that has been given to the Committee to-day?—Yes.

1046. You heard Dr. Jacob give evidence to-day with reference to a doctor of the age of 82, who is now serving in the county Waterford, and who is in infirm health, who

has served a vast number of years; do you not think that it would be expedient for the public service that that officer should resign?—Yes, if he is infirm and unfit for the duty.

1047. You must take my proposition again as I put it. A man of 82 and infirm, with a great deal of travelling to do, and a great deal of medical attendance; do you not think that it would be expedient for the public service that the man should resign?—If I were a guardian of that union I should call upon him to resign.

1048. Would not it be very harsh upon him to call upon him to resign and not give him a farthing of pension?—I do not think so.

1049. Now take another case stated by Dr. Jacob. A man 79 years of age who has served 50 years, that is half a century, and was blameless and never censured in the discharge of his duty, and is now utterly broken in health; is it not for the interest of the public service that he should resign?—I do think so.

1050. Do you consider that it would be grossly harsh and unfair to that man who has given his whole lifetime in the public service, that he should not have a fair pension?—If the circumstances are as you say it might.

1051. The circumstances are as I say; a man 79 years of age, who has served 50 years, and blamelessly conducted himself, is it expedient for the public service that that man should resign; would it not be grossly unfair to the public to compel him to resign and not give him a pension. Do you think so or not?—I consider if the circumstances are as you put them, and the man is unfit for duty, it would be for the interest of the public that he should be called upon to resign.

1052. So do I, but I do not ask that; I ask you, do you consider that his being called upon to resign, in fairness he is entitled to a pension?—In the case of all dispensary and medical officers I consider that they should not get any pension at all; I have a most decided opinion upon that point.

1073. Can you state to the Committee any case in your own personal knowledge where the Belfast Union has refused to give a pension?—I do not know of one, for the very simple reason that I do not know of any who have applied.

1081. Mr. Meldon: May I ask whether you happen to know whether your board of guardians are in favour of superannuation, or are against it?—I think they have no opinion upon the subject, the applications have been so few.

1082. Are you aware that only on two occasions have your board ever refused superannuations?—There were only two cases within ten or twelve years—one granted and the other refused, and that case was refused by the Local Government Board, and not by the guardians.

1084. Would you be surprised to hear that since 1876 there have been no less than 10 cases of applications for superannuation to your board of guardians?—In what year?

1085. Since the year 1875 or 1876?—I was not a member of the board of guardians then.

1086. Are you aware that since the passing of the Act there have been no less than 10 applications to your board of guardians for superannuation, and that of those 10 but two were refused?—I am not aware of it.

1103. Mr. Biggar: With regard to the dispensary doctors outside, in Belfast, could you form any idea as to the greatest length of time that any one of the present dispensary doctors has been in the service?—Their appointments are nearly all recent; that is to say, the oldest may be 10 years in the service, or nearly so, and the most recent appointments are not more than four or five years.

1104. Then from your experience have you ever known a case in which a dispensary doctor has retired from ill-health or from old age?—I never knew a case of a dispensary doctor resigning from ill-health or old age.

1109. Is it the fact that with regard to the dispensary doctors with whom you have come in contact in the capacity of secretary of the dispensary committee, you have found a very substantial variation in their character for good conduct and attention?—My experience of the dispensary medical officers from acting over three years as honorary secretary, was, that they had a very strong inclination to attend to their private practice first, and the public afterwards.

1110. You have found them exceedingly attentive?—Yes, I would say attentive.

1112. Would you think it a proper thing, that the same rate of salary should be given to the gentlemen who were very attentive, and that they should be pensioned at the same rate as others who were less attentive?—In my opinion none should be pensioned, but I would vary the amount of pension, if there is to be a pension, in accordance with the respective merits of each officer.

1113. Would you think that although no very special cause of complaint could be made against a dispensary doctor, he would necessarily be entitled to have a pension, although no very special charge was brought against him where he had been more or less negligent in the general conduct of his duties?—I would consider that although no special case might be made out if the question was submitted to the guardians, the opinion that I would express would be that he was not entitled to so much as a medical officer who was attentive and discharged his duties properly.

1116. A question was asked you with regard to the visiting lines; is it a common or an uncommon thing in your experience for the dispensary doctors to make the claims for visiting fees?—I have known some instances in which they have reported to the dispensary committee that they have been given lines by the relieving officer to attend cases which were not deserving cases.

1117. That is not common, is it?—It has been of frequent occurrence.

1118. What has the result been?—The result is that on the medical officer making such a report, the dispensary committee have almost invariably cancelled the line issued by the relieving officer.

1119. Then the doctor ceased to attend the patient?—The doctor ceased to attend immediately upon the cancellation of the line.

1120. How often do the committee meet?—Once a month only.

1121. With regard to the Local Government Board, to what extent do you find that they perform their duties with regard to the applications made by the guardians to them in reference to officials?—In many cases the Local Government Board are very inattentive, and I would even go so far as to say negligent in the discharge of their duties.

1123. Sir Patrick O'Brien: You have mentioned the conduct of the medical officers. Did you consider it part of your duty as a member of the Poor-law board of Belfast, having observed the conduct of medical officers as stated in your answer, to report any of them?—I did.

1124. To whom did you report?—It was my duty as secretary to find fault.

1125. You reported?—I found fault.

1126. You did not report?—Upon two occasions I brought the conduct of the dispensary officer before the dispensary committee.

1127. Was there a vote taken upon it?—Yes.

1128. What was the result?—The result was that they were instructed to be more particular in future.

1129. The vote was to that effect?—Yes.

1130. Did you hear Dr. Jacob's evidence here to-day?—I did.

1131. Did you concur with him when he said that it would be most desirable that old men unfit for their work should retire, not in the interests of the men themselves, but in the interests of the poor of the district?—I

the operation may be sometimes successful. It was lastly pointed out that the stretching of a small nerve on a hook acts differently from the stretching of a large nerve with the finger. In the latter class of cases the effect is probably either a loosening of the nerve from its sheath, or some influence on the nervous centre; in the former it causes a solution of continuity of the nerve, but with a certainty of union. The *modus operandi* is, therefore, probably not a profound effect upon the centre, as has been supposed, but merely the breaking of a bad habit, which must be taken for what it is worth.

Mr. PAGE was of opinion that the operation had been more frequently performed than was implied by Mr. Godlee's remarks, and that it was premature to speak of finality in respect to it. He referred to a case operated on by Mr. Pye, and another in which he had himself resorted to the same proceeding for relief of long-standing facial paralysis, in which all other remedies had been tried in vain. The first consequence of the operation was complete paralysis, and, subsequently, return to a condition of slight improvement on the original state. Prof. Braun had recently published observations tending to show that nerve stretching tended to the production of distant lesions.

Dr. ANDREW CLARK observed that Mr. Godlee's paper was an excellent illustration of valuable work. He agreed, however, with Mr. Page that all the cases had not been referred to, and instanced one in which, two years ago, Mr. Hutchinson successfully operated on the facial nerve.

Mr. H. H. CLUTTON on a case of

SPONDYLITIS DEFORMANS.

The patient, who had been exhibited at a previous meeting, was 30 years of age, and the subject of a very severe form of anchylosis of the spinal column. In the family history there was nothing to indicate hereditary taint. In his previous history there was strong evidence of rheumatism affecting the joints. When nine years old he was confined to bed for rheumatism, which, with several intermissions, lasted for six months. It began in the metatarso-phalangeal joint of the right big toe. It then attacked the right knee, and finally the right hip. The latter joint had, he said, remained stiff ever since. Six years ago he had a painful foot, which the doctor called rheumatic gout. He had never had any venereal disease of any kind, and beyond the attacks above described had always had good health. Three years ago he first felt pain and stiffness in his neck, but it had caused him little inconvenience till the last six months. He can give no account of his back or chest, and is not aware that they are fixed and immovable. For the last three months his left shoulder has been stiff and painful, and he still occasionally suffers from rheumatic pains in the right hip. His present condition is one of almost complete anchylosis of the spinal column. He stands with the left leg advanced in front of the right, with the knees bent, and in a stooping posture. His spine presents one large dorsal curve, with the convexity backwards. The head is craned forwards, and the chest sunken and depressed. The movements of the head are very much impaired, although not as yet completely destroyed. He cannot turn his head at all to the right, and only slightly to the left, the nose moving about one and a-half inches from the median line. The lateral movements ordinarily obtainable in the cervical region are entirely absent. In raising and depressing the head, the chin only moves three inches. There is no movement whatever in the lower cervical vertebra. This is very apparent on trying to make the patient bring his chin towards the sternum. On bending the whole body forwards, it is seen that the spinal column is quite rigid; there is no separation between the spinous process, or increase of curve. With the knees extended, the tips of the index fingers just touch the patella, and this movement appears to be effected by the hip-joints. The respiratory movements are entirely abdominal. On the deepest inspiration there may be some slight expansion, but there is no elevation of the ribs. His height is now 5ft. 2in. in his boots, and he is quite sure that some years ago he was 5ft. 5½in. when measured in his boots against the wall. As to other osteo-arthritis changes, the patient has several creaking joints and distinct "lip-growths" in both shoulders and big-toe joints. He has also distinct limitation of movement in the left shoulder. The right great trochanter is larger than the left, and tender on pressure. All the other joints except those named seem perfectly healthy. Such an extensive and severe form of anchylosis of the spine, with or without osteo-arthritis changes elsewhere in the body, is a rare condition in

a man 30 years of age, and it was on this account Mr. Clutton brought him before the Society. A similar case was shown at this Society by Dr. Allen Sturge, and is recorded in the Clinical Society's "Transactions," vol. xii.

Dr. LEDIARD on a case of

SPONDYLITIS DEFORMANS AND OSTEITIS DEFORMANS.

The patient was a miner, *æt.* 58, from Cumberland, who had suffered from repeated attacks of pain in the spine, and rheumatic affection of the joints, and of late years stiffness of the spine and head, so that the body was bent forwards in a stooping posture. The spine was absolutely anchylosed except for slight movement in the neck, and the head was firmly fixed to the spine. Several joints presented chronic rheumatoid arthritic changes; there was no movement of the chest walls, respiration being entirely diaphragmatic. The femora were curved forwards and outwards, and the shafts, somewhat massive, suggesting the disease known as osteitis deformans in possibly an early stage. The skull and clavicle were, however, unaltered.

Dr. DYCE DUCKWORTH said it was difficult to account for the rarity of the disease if it was due to rheumatic arthritis. Mr. Hutchinson put the origin of many such cases in gonorrhoeal attacks, but he was uncertain if this experience was borne out by that of other surgeons. It was fortunate the disease was so rare, since it was so hopeless of cure.

Mr. CLUTTON said that, in spite of particular inquiry as to the occurrence of gonorrhoea in his patient, no proof of this had been obtainable.

Mr. GEORGE LAWSON related the history of

TWO CASES OF EPITHELIOMA WHICH HAD OCCURRED ON OLD CICATRICES, AND WHICH HE HAD REMOVED.

In the first case, the patient, a pale, anemic woman, *æt.* 38, had lost, in childhood, the sight of both eyes, except the bare perception of light, from an ulcerative inflammation, probably diphtheritic, and which had caused complete adhesion of the upper and lower eyelids of each eye to the globe. The patient was admitted into the Middlesex Hospital in May, 1881, and the growth first commenced in the previous September. It sprang from the cicatricial tissue which united the left lower eyelid to the globe, and steadily increased until it obtained the dimensions shown in the drawing, the whole front of the eye being occupied by it. Mr. Lawson removed the growth and the eye. Two years has now elapsed since the operation was performed, and there has been no recurrence. In the second case, the patient, a strongly-built man, *æt.* 30, was admitted into the Middlesex Hospital in March, 1881, with an epithelioma of the left thigh, which occupied the greater part of a large cicatrix. Twenty years previously his left thigh was crushed by a heavy cart passing over it, which caused great laceration of the skin and muscles. He was seven months in the Aylesbury Hospital, and when he was discharged there was still an unhealed superficial wound of about the size of a small saucer. He then went to work as a farm labourer, but the wound never healed. Two years and a-half before his admission into the Middlesex the wound took on a new action. It began to spread rapidly, the granulations became large and fungoid, and it occasionally bled. On admission, there was found an epitheliomatous ulcer measuring seven and a-half inches by eight inches. Mr. Lawson amputated the thigh just below the trochanters, and although two years have elapsed, there has been no recurrence of the disease. Mr. Lawson remarked that the cicatrices which seemed specially prone to epithelioma were the tight cicatrices such as are caused by a great destruction of skin, and those cicatrices upon which there is a constant tension. Both the cases, he said, tended to show that if epithelioma can be completely excised before it has affected lymphatic glands, it is the form of cancer which is the most amenable to treatment; whilst experience has taught us that after the lymphatic glands are invaded, epithelioma is the most formidable and irremediable of all the cancers.

Mr. GODLEE asked whether the epithelioma arose in the centre or at the circumference of the cicatrix.

Mr. LAWSON said that in his own case it arose at the margin of the scar.

Mr. WARRINGTON HAWARD observed that the cases described pointed to the conclusion that in such forms the disease was purely local; and he cited a case in which the region of a large burn was for twelve years subsequently the site of a granulating sore. Then active fungation set in, and much pain was experienced. Skin grafting was tried without result,

and amputation of the leg—which was the part affected—was performed, an epitheliomatous structure being clearly seen in it. There was no history of cancer in the patient's family for some generations before, and now, seven or eight years later, she continued in good health, having had no recurrence of the growth. Other examples could be quoted of long unhealed sores resulting in cancer, and they taught that immediate removal of such parts should be adopted.

Mr. BAEKER also regarded the cases as affording striking proof of cancer originating from local irritation.

Mr. PEARCE GOULD mentioned two cases treated in the Westminster Hospital, one, that of a woman in whom cancer spread from the edge of a scar on the thigh; and the other, of a man who had been shot in the leg eleven years previously, and in which case epithelioma spread round small sinuses communicating with shot remaining in the tibia. The resemblance of such less malignant forms of cancer to rodent ulcer was insisted on by Mr. Pearce Gould.

Dr. ANDREW CLARK inquired whether Mr. Lawson had found cancer originate in syphilitic cracks in the tongue.

Mr. LAWSON replied that syphilitic tongues were more commonly cancerous than non-syphilitic. He regarded irritation as a common cause of cancer, and thought that the epitheliomatous growths under consideration might be managed in their early stages, but were intractable later. In operating, however, the whole of the affected tissue must be removed.

Dr. RADCLIFFE CROCKER read the case of a girl, *æt.* 12, with
NODES FROM CONGENITAL SYPHILIS.

The patient had been shown at a previous meeting. She had enteric fever five months before she came under notice, and during convalescence, two nodes appeared on the forehead, one on each side of the median line; there was another tumour in the right orbit, softer than the nodes and movable. There was no corroborative evidence about the girl except the two upper central incisors, both of which were notched, and one was slightly pegged. No history of infantile syphilis could be obtained, and the mother and the other children were apparently quite healthy; but eventually it was ascertained that the patient was a child by a previous husband, who died soon after their marriage, had lived a dissipated life, and was never well, but resented inquiries into the cause of his ill-health. The patient was put under iodide of potassium, and when last seen the softer tumour had quite gone, and both the nodes were softer and much smaller, and the improvement in the general health of the patient was very striking. Dr. Crocker remarked that the case corroborated Sir James Paget's observation that typhoid fever often aided as the discoverer of constitutional taint, and also Mr. Hutchinson's observations on the value of the notched and pegged incisor teeth as evidence of congenital syphilis.

Dr. FREDERICK TAYLOR on a case of
INFANTILE HEMIPLEGIA WITH UNUSUAL REFLEX PHENOMENA.

The patient was a child, *æt.* 5, who was taken with convulsions at twelve months old. These lasted two hours, and were followed by weakness of all the extremities. In a few days the right arm began to move, and the right leg, but the left limbs remained paralysed. Gradually rigidity developed, and with it the curious reflex irritability to be described. The child was fat and well, commonly semi-recumbent, with both legs semi-flexed and rigid, the left arm flexed at all joints and rigid. This arm is scarcely used, but the right freely and well. Both legs can be moved, but not completely flexed or extended. The right is less rigid than the left. The child cannot sit up in bed, nor stand upright, nor walk. The left arm and leg are nearly two inches shorter than the right arm and leg respectively. On making a sudden noise near the patient the left arm is quickly thrown out at right angles to the body, the elbow, wrist, and fingers are extended, the face assumes a puzzled expression, and the legs undergo moderate extension. The condition of spasm remains for about thirty seconds, then slowly relaxes. The same reflex contractions are brought about by shocks affecting the surface of the body, a blow on his crib, a tap on the head. Vision appears to be good, but he has disseminated choroiditis in very small patches in both eyes. He is lively, fairly intelligent, and can talk. He passes feces and urine involuntarily. But for the choroiditis there is no conclusive evidence of congenital syphilis. He has been four months treated with iodide of potassium and mercury, but shows no material improvement. Dr. Taylor thought the case was allied to those of infantile hemiplegia with spastic or choreic phenomena occurring

afterwards. Though not strictly unilateral, the disease on the left side was obviously of cerebral origin, and that on the right side must be explained by a second lesion, or more likely by a single lesion crossing the middle line. The mode of origin suggested obstruction of a vessel, with syphilis as a possible antecedent. Its early occurrence and the deficient growth of the left limbs rendered it probable that asymmetry of the brain also co-existed.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

A METHOD OF RENDERING THE SKIN INSENSIBLE IN OPERATIONS WITHOUT CHLOROFORM.—M. Jules Guérin read a note at the Académie des Sciences upon a method of rendering the skin insensible in those operations which do not admit of chloroform by inhalation, and cited a case in which he had employed it to advantage. A lady, *æt.* 60, consulted him three months ago for a tumour in the right breast of eight years' standing, which, on examination, proved to be a scirrhous. The general health was bad, bronchial and cardiac troubles were very manifest, and the kidneys were not in a very satisfactory condition. However, the operation was urgent. Chloroform having been considered dangerous, M. Guérin applied around the tumour a circular layer of Vienna paste, limited by a double band of diachylon. At the end of twenty minutes the caustic was removed, leaving in its trace a black ribbon-like line. The knife was then applied, and the tumour removed without the patient feeling the slightest pain, and who did not seem to be aware of the operation. The results were all that could be desired.

ANKYLOGLOSSIS.—At the meeting of the Société de Chirurgie a member invited the opinion of his colleagues in a case of ankyloglossis which had come under his notice. The patient was an infant, two months old, and from the peculiar position of the tongue, which was totally adherent to the floor of the mouth, the child was unable to suck, and consequently was rapidly wasting away. He thought that an attempt might be made to disengage the tongue by the thermo-cautery, but waited the opinion of his colleagues. M. Champonnière said he had seen a child presenting a deformity analogous to this case. The tongue was fixed to the floor of the mouth in its whole length. With the scissors he was able to set free the point, and the child was able to perform suction satisfactorily. He did not see why a similar operation should not be tried in the case under consideration. M. Verneuil could not believe that such a simple operation would be attended with a sufficiently satisfactory result in this case, although it might suffice where the deformity was not so complete. M. Trélat had occasion to observe a case of ankyloglossis in which the tongue was attached to the floor of the mouth by two fimbriated mucous folds, one on each side. A cut with the scissors sufficed to set free the organ. He might suggest that it was possible that a similar disposition of the parts might be found in the case of his *confrère*. M. Sée observed that, if the tongue was simply separated from its adherences a relapse was sure to occur. It would be necessary in consequence to interpose between the two surfaces a piece of mucous membrane which might be taken from the cheek. M. Tillaux was of opinion that nothing should be done, as an operation on a child two months old, weak and sickly, could not be followed by any good results; it was better to let a child die quietly than to kill it. After some other remarks from different

members, the subject dropped, but not before the member, who had charge of the case, expressed his determination to hazard some kind of operation.

BRIGHT'S DISEASE.—At the Académie de Médecine M. Seminola, of Naples, explained his theory on Bright's disease. According to him, the alterations observed in the renal tissue are not the cause, but the result, of the infiltration of albumen. The disease attacks the liquids before the solids. The albumen is altered in its quantity and composition. Its characters in the serum of the blood are not normal, and consequently it must be eliminated from the economy. M. Seminola injected by little quantities under the skin of healthy animals albumen of different kinds. After some time the kidneys became affected in a similar manner as that observed in Bright's disease. This new theory was tacitly received by the meeting, and immediately afterwards a discussion on the report of the Typhoid Fever Commission was commenced. This Commission was formed to furnish the authorities with advice on the best prophylactic means to be adopted against that affection.

A FURIOUS ANTI-VIVISECTIONIST.—M. Brown-Séguard was interrupted rather brusquely the other day in one of his courses of experimental physiology at the College de France. A monkey was brought on the table and the learned physiologist commenced his lecture by explaining the nature of the experiment about to be made on the animal. The monkey seemed evidently well-pleased by the observations, for he highly amused the whole audience by his mimicries. But when the lecturer went to seize him he cried most piteously, as if he had a presentiment of what was in store for him. Having thrown him on his back and bound him, M. Séguard took the scalpel and, was in the act of plunging it into the animal, when, to his great surprise it was adroitly sent whirling across the room by a straight tip from the umbrella of an indignant lady member of the Anti-Vivisection Society. The humiliation of the lecturer can be easily imagined, however, recovering his *sang froid* he requested his assailant to leave the Hall, but was met with a stern refusal from the lady, who said that, as she had no other way to show her disgust for such practices, she had determined to prevent them by the means she had chosen. However, the influence of an *agent de paix* was brought to bear on this member of the gentle sex and she left, protesting all the way. The scalpel was picked up, and now that his defender was gone poor monkey had to submit *bon gré mal gré* to the operation in question, and the lecture was finished without further interruption.

RESECTION OF THE LUNG.—Your correspondent is always glad to be corrected when he inadvertently makes a mistake, either as to the name of authorities or the subject of facts. But at the same time he is generally surprised when one of those rare occurrences take place, as he is always very careful as to the selection of his sources of authority. In any case, although it is quite possible that the credit of such an operation is not to be attributed to Koch of Berlin, but another Koch, the fault is not to be laid at the door of your French correspondent, but at that of the *Bulletin de Thérapeutique*, a journal always well-informed and edited by several of the best lights of the metropolis. The article commences thus, "Koch de Berlin très connu dans le monde scientifique pour ses recherches sur le bacillus de la tuberculose vient de tenter une operation, &c. I would advise "the writer of the summary" to exact without delay a correction in the journal referred to, as it seems of such importance to him. There is no doubt he will get every satisfaction.

MEDICAL ACTS AMENDMENT BILL.

A STATEMENT of their case has just been issued by the Royal College of Surgeons in Ireland which embodies, as we think, most of the points which can be urged by the Irish licensing bodies, and is, therefore, worthy of special notice.

With reference to the constitution of the Irish medical Board the College proposes that the Irish Medical Board shall consist of thirteen members, *i.e.*, twelve from the licensing authorities which are recognised by the Bill, together with the direct representative for Ireland; and it submits that the Colleges of Physicians and Surgeons should not have a smaller combined representation on the board than the Universities, because (a) the medico-educational work done by them is much greater, and (b) the medical examination standard, as evidenced by the percentages of rejections, is not, in any respect, lower than in the case of the Universities.

As regards the standard of general education required for their admission to the profession, the College recognises the claims of Graduates in Arts, or of Undergraduates in Arts, of three years' standing, to a special exemption from examination fee, but it does not admit that other University students are entitled to any special consideration, or that bodies which grant qualifications to candidates of lower Arts standing than three years have any claim to predominant influence in the Medical Board.

The College submits that the representation of the Irish licensing bodies in the medical board which it urges is consistent with the principle upon which such representation has been fixed in the other divisions of the Kingdom. In England the licensing of the great majority of practitioners is effected by the Colleges of Surgeons and Physicians, and, therefore, a large predominance of representation in the Medical Board is given to these two bodies, which return as many delegates as the five universities combined, the result being an equally balanced influence between the universities and the colleges. In Scotland, on the other hand, the greatest proportion of medico-educational work is done by the universities, which are, therefore, given a predominant representation of 8 to 3.

Admission of the Direct Representative to the Medical Board.

The College is of opinion that the Bill will not be acceptable if the direct representative be excluded from a seat at the Medical Board of his own division of the Kingdom. One of the chief purposes of the reconstitution of the Medical Council was to give the profession at large an influence in education and examination; but the Bill does not fully effect this object, for it limits the direct representative to the occupation of a seat for a few days annually in the Medical Council, with a vote as one of eighteen members, in the exercise of the supervisory powers of that Council. The direct representative for Ireland, for example, would have no direct voice in the arrangements for preliminary or professional education—the appointment of examiners—the regulation of fees for study or for examinations—the recognition of examining bodies in Ireland, or any of the other functions of the Board. These important matters would, in the absence from the Medical Board of the Crown nominee and the direct representative, be ruled exclusively by the delegates from licensing bodies, an arrangement which the Bill is expressly intended to prevent.

Uniformity of Educational Standard throughout the Kingdom.

The College strongly urges that it shall be impossible for the Medical Board of any one division of the Kingdom to accept a shorter and cheaper course of medical study for its examinations than that required by another board. The chief purpose of the Bill is to ensure competency of the practitioner, by requiring a sufficient minimum of education, and to put a stop to the practice of students who are not educated up to the requirements of their own country,

resorting to institutions of a lower educational standard elsewhere. The Bill attempts to meet this downward competition between Medical Boards by providing for uniformity of examination, but it permits any amount of downward competition in curriculum of study.

This lowering of the extent of courses of study and consequent cheapening of education has, in fact, caused a migration of a very large number of Irish students from their place of education to seek qualifications from licensing bodies elsewhere which accept a lower, briefer, and cheaper curriculum; proof of this statement can be found in the evidence given before the Royal Commission.

This College does not desire to limit schools as to their method of teaching, so long as that teaching is *bona fide*, and it is entirely willing that the course of study shall be fixed as the Medical Council deems expedient; but urges that whatever studies be considered indispensable they would be imposed strictly upon the students of every division of the Kingdom without exception.

Education and Examination Schemes to be made by Medical Council.

The College is strongly of opinion that the subjects and extent of final examinations, and of the required courses of study, should be fixed by the Medical Council, and not by the local Medical Boards. As the Bill now stands, each Board would make, in all probability, its own scheme of a totally different scope and character from those of the Board, and the Medical Council would be obliged to bring these schemes into uniformity against the opinion of the Boards, and, probably, in face of frequent appeals to the Privy Council—a system which would obviously increase enormously the labour and cost of making a general scheme.

Allocation of Surplus Funds.

Under the Bill two sorts of funds are contemplated—*a.* Three local Medical Board Funds, resulting from the surplus of the fees paid to local Boards for final examination, over the expenses of same; *b.* A Medical Council Fund, resulting from the assets from the three existing Branch Councils, plus the fees of £5 each for registering practitioners.

Fund *a.* (the Local Fund) is applicable, *inter alia*, after payment of expenses, to maintenance of "medical museums and medical libraries belonging to a medical authority." Fund *b.* (the General Fund) is applicable "for the benefit of the medical profession, or in such manner as the Medical Council may, with the consent of the Privy Council, determine."

The College solicits attention to the operation of these arrangements in Ireland. Fund *a.* would probably be insignificant in amount, because University undergraduates would be exempted from contributing to it, and the entire expenses of maintenance of the local Board and payment of examiners would constitute a first charge on it, therefore the surplus available for maintenance of Irish "museums and libraries" would probably be very small.

Fund *b.* (the General Fund) would, on the contrary, be large. It would start with the aggregate capital of the three existing Branch Councils (£29,000 + £2,000 + £1,869), amounting to £32,869, and yielding an interest income of nearly £2,000 a year. It would have also an income of almost £6,000 arising from registration of practitioners; and against this total income of £8,000 it would expend for the Medical Council and its establishment about £3,500, leaving a yearly profit of about £4,500 available for any purposes within the wide area of the phrase quoted above.

The College submits that the maintenance of great Irish educational institutions ought not to be left either to the insignificant local Fund or to the unlimited discretion of the Medical Council, of whom only four members will specially represent Ireland, and it proposes that the Medical Council Fund shall be allocated to each division of the Kingdom proportionately to the medico-educational work done therein, and shall be there distributed by the local Medical Board. It appears, taking the three

years last passed, an average of 2,048 new students were registered each year throughout the Kingdom, of whom England supplied 966 annually; Scotland, 580; Ireland, 502; total, 2,048. Calculating on this basis and dividing the gross central surplus fund into hundredths, it appears that, in respect of its medical educational work, the English Divisional Board should receive 47·1 per cent. of the entire fund, Scotland 28·3, and Ireland 24·5.

Exemption of University Undergraduates from Examination Fee.

Clause 36, page 22, lines 19 *et seq.* declares that "the fees (for final examination) to be paid by University graduates or undergraduates holding University certificates of having passed the examinations at their University . . . shall not exceed the portion of the fee leviable . . . for the administrative expenses of the Board." The College is willing to accede to this concession to full Arts graduates of Universities or to undergraduates of at least three years' standing in Arts; but it altogether disents from the proposition to extend such privilege to students who are only University undergraduates in name, and who have not acquired a claim—by *bona-fide* academic studies—to the enjoyment of such privileges. The College draws a marked distinction between Universities such as Oxford, Cambridge, and Dublin, which accept no candidate for their medical degrees but those who have fulfilled a complete curriculum in Arts as well as in Medicine, and those other Universities which grant their highest medical degrees to students who are little more than matriculants, who pass but one, or, at most, two preliminary examinations of no higher standard than the analogous examinations of the College,—who are examined, but not, in any respect, educated in these Universities,—who do not reside therein, and who are not called upon to pay the cost of complete Arts studies. Such Universities, being simply examination centres, have even less claim to special privileges than this College, which both educates and examines and maintains for purely public purposes an educational establishment of the greatest value, without calling upon the public purse for any assistance.

Affiliation of Examinees to a Licensing Body.

The Bill confers on the examinee of the local medical board a right to be registered and to practise, but it does not give him a title by which his *status* shall be indicated. The College is of opinion that an examinee who has passed his primary examinations at a College or University, and his final examination before a medical board should be affiliated by the College or University *ipso facto* without additional examination, and upon a small fee (if any). But it would be an abuse of the system if such students should go off to another licensing body and obtain its diploma without having been associated with it during studentship, or having passed any examinations therein.

Signed, as delegates for the Royal College of Surgeons in Ireland,

WILLIAM IRELAND WHEELER, President.
 RAWDON MACNAMARA, Representative on
 General Medical Council.
 JAMES KELLOCK BARTON, Past President
 and Councillor.
 ARCHIBALD HAMILTON JACOB, Councillor.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JUNE 27, 1883.

THE MEDICAL BILL.

THE position of the Bill as one of the secondary measures of the Government is becoming every day a subject of greater anxiety to reformers, for, though Ministers are evidently determined in passing it, if at all possible, yet the embarrassments of Government legislation are just now so great that an organised opposition would certainly be fatal to the measure this session.

We understand that the Government will probably devote Saturdays to this and other secondary Bills, including a London Police Bill (which is considered of first importance), the Union Officers' (Ireland) Superannuation Bill, and other class legislation which still hangs fire. On these Saturdays the rule that opposed measures shall not be taken after midnight cannot be availed of to stop progress, because the House sits at noon and goes on without limit, and ample time is thus afforded to take opposed Bills before midnight.

Nevertheless an organised opposition could interpose insuperable difficulties, and it is for this reason especially that we regret to observe that Mr. Mundella has evinced a disposition to refuse consideration even to reasonable amendments, which, being consistent with the principles of the measure, might be conceded to the licensing bodies which put them forward. In this respect we think

that the attitude of the Minister, as well as the policy adopted by certain representatives of medical reform, is extremely unwise.

These advocates of reform think that they most effectually support the Bill by declaring their readiness to swallow it entire without particular inquiry as to its ingredients. They represent the profession as being so hungry for direct representation that it will thankfully accept any Bill which contains that concession, and without waiting to inquire whether the measure is in other respects acceptable, or whether it really provides for the one point which they consider essential. By reiterated begging for this boon they have, we fear, succeeded in persuading Mr. Mundella that, so long as he grants it, he need not trouble himself with the other details of the Bill, and they have thus caused him to assume an attitude toward remonstrants which is, we think, in the last degree undiplomatic.

These representatives of reform of whom we speak seem entirely to forget that, if they abstain from seeking to improve the Bill, their doing so will not in any material degree relieve the Government from the pressure of amendments promoted by other parties, and Mr. Mundella would be wise to recollect that these amendments cannot be met with flat refusal, unless the Government is prepared to make the Bill a Cabinet measure of the first order, and force it through by the votes of the Government majority.

We feel that it is not reasonable for the Government to meet suggestions for improvement with the declaration that reformers must take the Bill as it stands, or no Bill, and we must say that, putting out of consideration the very influential class in the profession who are hostile to reform, and would be delighted that the Minister would carry out his threat to abandon the measure, there is also a large section of reformers who would almost prefer to wait and agitate for another year or two rather than accept for the next twenty years a defectively reconstructed system.

We would, therefore, earnestly advocate a change of policy before it is too late. The Bill will probably not be seriously opposed on second reading if the licensing bodies have reason to hope that they will have fair play when the Bill goes into committee; and, therefore, with a view to smooth the way for further progress, we think that the advocates of reform ought to help the Government by suggesting concessions, and that Mr. Mundella ought to consider the suggestions in a compliant spirit so long as they are neither impracticable nor inconsistent with principle.

We warmly support the Government in refusing to sacrifice principle or important detail to the individual interest of any licensing body, but we cannot approve of a determination to hear no remonstrance or make no concession; nor can we listen to a repetition of the formula that if the profession does not like everything the Bill contains it will get nothing else.

THE RECENT ANTI-VACCINATION COLLAPSE.

NOTHING that has occurred within recent times has more conclusively demonstrated the arrogant pretensions of anti-vaccinators than the debate and its result

on Mr. Peter Taylor's motion in the House of Commons last week. Taking the figures descriptive of the feeling entertained by members of Parliament as a basis of calculation, we find that 16 out of 286 persons favoured the views expressed by Mr. Taylor and his party—that is, about one in every 18, or, as nearly as need be, 5.5 per cent. These numbers may without much hesitation be accepted as indicating also the proportions of those who do and those who do not believe in the protective influence of vaccination, among the general population of the country; and on this calculation it would appear that the adoption of Mr. Taylor's opinions must entail an absolute exercise of tyranny by what is at best an insignificant minority, against an overwhelming majority of the people.

But this is not the worst outcome that would ensue were common sense less prominently enlisted on the side of preventive legislation; for the universal experience of those who follow and appreciate the masterly logic of Dr. Cameron's and Sir Lyon Playfair's admirable speeches is to the effect that vaccination, and vaccination only, confers that comparative immunity from small-pox which this country enjoys under the operation of a compulsory Act. In opposition to this overwhelmingly preponderating majority of 18 to 1, the few whom facts and science cannot conquer, still seek to rear their sentimental prejudices; and on grounds which never were so unsparingly laid bare as during the debate to which we have referred.

We are not certain whether events do not justify the aspiration that henceforward no further occasion will arise to call forth determined criticism and refutation of anti-vaccinating ideas. In spite of hearty and unceasing efforts, by paid agents and by fanatically-animated agitators, to inoculate the public with a hatred of compulsory salvation, the anti-vaccinators have in the course of all these years secured no more than one-eighteenth part of the community in their favour; we may, therefore, well be content to rest satisfied that the movement is fruitless to stem advance, and that little need arises for any more arbitrary enforcement of saving clauses. Notwithstanding, however, it is our bounden duty to continue alive to the claims humanity possesses—even when most misguided—on our efforts to save it from its worst enemies; and to strive for the safety of even the few who fail to understand the folly of resistance. That the crushing defeat suffered by Mr. Taylor will open the eyes of many who have believed in him, we willingly recognise; but error is long-lived, and no matter how extreme it chance to be there are always some who from interest or ignorance submit to its dictates. So even now, the serpent is scotched, not killed; nor will it be until either the listlessness of despair overtakes the advocates of free-trading in disease, or—hopeless as it may appear—the dictates of common sense and common humanity prevail over the whisperings of self-seeking and self-interest.

It would be improper to withhold the hearty congratulations due to Sir Charles Dilke for his eloquent vindication of the Government, and his out-spoken determination, on its behalf, to maintain an efficacious

prevention. Sufficient justification has, unfortunately, been given of a feeling of mistrust in regard to the attitude which might have been assumed by ministers who could approve the mischievous policy of Mr. Stansfeld's following. Good cause had been given for doubting to what extent the present Cabinet might not be disposed to go in treating with noisy agitators who set up the fetish of personal liberty as an idol for universal worship. In this instance, however, national interest has ruled supreme; and it is sincerely to be hoped that the unmistakable majority—270 in a house of 286 members—by which Mr. Taylor's insidious attempt to abolish compulsory vaccination was rejected will, at any rate for a time, relieve the country from further annoyance by a clique whose principal aim is subversive of the nation's welfare.

THE TUBERCLE BACILLUS WAR IN GERMANY.

THE tubercle bacillus question continues to occupy a prominent position in medical thought in Germany. On the whole, the balance of opinion is in favour of the views advanced by Köch; but opinions are anything but unanimous. As we have already informed our readers, these views have been traversed by Dr. Arnold Spina, of Vienna, in every, or almost every, particular. The objections of Spina have, as we have also stated, been received as valid by Professor Stricker, whose assistant Spina is. Some time ago the former announced to the Medical Society of Vienna that Spina was engaged in making further investigations, the results of which would be made public when completed. In order that the results thus about to be published should be as reliable as science and skill could make them, the Vienna professor told off two other assistants, Drs. Kaberhel and Mátray, to conduct a series of control experiments. The outcome of Spina's new work, and of Kaberhel's and Mátray's check experiments, was communicated to the Vienna Royal Society of Physicians on the 11th of May, and prefaced by some remarks by Stricker, who stated that he had only superintended the work done. In the discussion that followed the reading of Spina's paper he explained his attitude towards Koch's doctrine, which was that he did not deny that tuberculosis was an infectious disease, but that the proofs that it was so, up to the present, did not stand.

Spina's paper was, to a great extent, a repetition of his previous arguments against the accuracy of Koch's teaching. He again maintained that the bacilli were capable of being permeated and decolourised by acids, and that no proof had been adduced that the so-called bacillus tuberculosis was a distinct species. He brought forward the discovery of Demme, of tubercle bacilli in three cases of lupus, and pointed out that according to this lupus must be a tubercular and infectious disease. Then, for the sake of argument, he says:—"I concede now that all the objections I have raised against Koch are unjustified; that Koch is right and I am wrong; that vesuvin and acids do not penetrate the bacilli; that they are only permeable to

IRISH POOR-LAW INTELLIGENCE.

IMPORTANT TO DISPENSARY DOCTORS.

THE Hon. Sec. of the Athlone Dispensary Committee has received the following copy of a letter from the Local Government Board :—

SIR,—I am directed by the Local Government Board for Ireland to acknowledge the receipt of your letter and of its enclosures relative to the refusal of Dr. White to act as temporary substitute for Dr. Langstaff, the medical officer of the Athlone Dispensary District, and requesting to be informed how you are to act under the circumstances, and whether the committee of management can appoint a substitute at Dr. Langstaff's expense, and in reply, I am to inform you that the board of guardians would not be authorised in making any deduction from Dr. Langstaff's salary so long as he continues in office. The committee of management should, however, make provision for attendance on the sick poor pending Dr. Langstaff's resignation, or his return to discharge his duties, and the Local Government Board presume that under these circumstances the guardians will, if necessary, agree to pay a temporary substitute for Dr. Langstaff, who has been on leave for an unusually long period.

By order of the Board,

W. D. WORDSWORTH, Assistant Sec.

To John M'Donnell, Esq., Hon. Sec.
Athlone Dispensary Committee.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

DR. THOMAS JOSEPH MOORE, examined.

(Continued.)

1274. I gather that the principle of sixtieths is in your view objectionable to the union officers outside the medical officers; would you prefer fiftieths?—I think the sixtieths would be a fair proportion to give, with the number of years stated in Clause 6 added.

1277. With regard to the existing superannuation enactments, do you think that the officers generally would prefer the option of retiring under the old legislation or under the new?—Most decidedly under the new.

1278. In any case would it be desirable to allow them an option?—No, the officers prefer the certainty of having superannuation granted to them according to the scale laid down by the Bill, with the 10 years added.

1279. As between the Local Government Board and the Board of Guardians having this power, which do you prefer?—It is immaterial to the Association what machinery is employed so long as security is given to the officers, and superannuation awarded them after long and faithful service.

1280. You mean to say if a man is to get £5, it does not matter out of whose pocket it comes, but that is not my point; supposing it is left optional, do you prefer to deal with the Local Government Board or with the guardians?—So far as my own board is concerned, to me it is immaterial, but the union officers would have more faith and confidence in the Local Government Board.

1281. Mr. Daly: The honourable chairman elicited from you that many boards of guardians were in favour of the Bill, and you went on further to say that there were 13 boards of guardians in favour of the Bill as originally introduced?—Yes.

1282. And that 20 were in favour of it, providing the pensions come out of the Consolidated Fund?—Yes.

1283. Then, strictly speaking, they are not in favour of the Bill, because the Bill does not propose that?—I take it that they were in favour of the principle of the Bill, that is making the measure a compulsory one upon boards of guardians.

1284. In fact what they did express themselves in favour of, was that the pensions should come out of a Consolidated Fund, and that was not in the Bill?—I do not think I made myself clearly understood; what I gathered from the union officers was this: where the boards of guardians approved of the Bill, provided the pensions were paid out of the Consolidated Fund, they approved of the principles of the Bill, that is to say, they approved of the measure being compulsory.

1285. Was not their approval simply this: we will be generous if it costs us nothing?—It comes to that I believe.

1286. Then there were 20 that took no action at all?—Twenty took no action at all.

1287. You have only accounted for 70 out of 163?—In considering over the question I think I have underrated it in my calculation; between the guardians who petition in favour of it, and those who took no action, and those who stated their willingness to accept the principle of the Bill, provided the pensions were paid out of the Consolidated Fund, there would be 90 unions out of 163.

1288. Then, in effect, you are not able to answer the question of the Chairman, that anything like a moiety of the boards of guardians were in favour of the Bill as it stands?—Only in the manner in which I have represented to you.

A LIVELY sensation appears to have been produced in Paris by a statement that some of the sulphate of quinine supplied to the French hospitals contains as much as 43 per cent. of cinchonine. *L'Union Pharmaceutique* throws the blame upon the system which allows the public service to be supplied with foreign quinine by contractors who are incapable of detecting a fraudulent substitution if they wished to do so.

IRISH MEDICAL ASSOCIATION.**REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL,***Read and adopted at a Meeting of the Council, held January 23rd, 1883.*

Dr. WHISTLER, of Bray (Vice-President for Leinster), in the Chair.

MEDICAL REFORM.

The Committee of Council have anxiously considered how they could best give effect to the oft-pronounced views of this Association regarding medical reform, and having been led to believe that Government intends to introduce in the coming session of Parliament a Bill embodying the recommendations of the Royal Commission on the Medical Acts, the Committee of Council decided on presenting a memorial to the Lord President of Her Majesty's Privy Council, offering the cordial support of this Association to any such measure. Accordingly the following memorial was recently presented by Dr. Jacob, on behalf of the Council, to the Right Hon. Mr. Mundella, Vice-President of the Privy Council, at his office in London, viz.:-

*To the Right Honourable the Lord President of Her Majesty's Privy Council.***THE MEMORIAL**

Of the President and Council of the Irish Medical Association,

Humbly sheweth—That your Lordship's Memorialists are the executive body of an incorporated association which numbers amongst its members more than one-third of the entire body of registered medical practitioners in Ireland, and which for more than forty years has been maintained in order to "unite the members of the medical profession in Ireland, and so form a body competent to exercise influence in sanitary and medical affairs for the public benefit, and to protect and promote the interests of the medical profession."

That your Lordship's Memorialists have learned with much satisfaction that it is the intention of Her Majesty's Government to introduce to Parliament a Bill for the amendment of the Medical Acts, based upon the recommendations of the Royal Commission, appointed in the year 1882, to investigate the subject.

That the Irish Medical Association has at many successive Annual General Meetings declared its approval of the principles embodied in the recommendations of said Royal Commission, and has petitioned Parliament in favour of those principles, and furthermore, expressed its opinion thereon, by testimony given on its behalf before said Royal Commission.

That your Lordship's Memorialists will be prepared to give the best support of the Irish Medical Association to any Bill which embodies the following principles:-

(a) To restrict the privilege of registration as a medical practitioner to persons who shall have passed before a central examination board for each division of the Kingdom, an examination adequate to ensure their competency—registration being granted throughout the Kingdom upon equal terms as regards standard of examination, duration of study, and amount of fees payable, prior to examination.

(b) To reconstitute the General Medical Council, so that an adequate direct representation therein of the registered medical practitioners throughout the Kingdom shall be secured.

(c) To amend the existing law, so as to check effectively the prevalent practice of medicine and surgery by uneducated and unlicensed persons, and the use by such persons of titles calculated to deceive the public as to their competency to practise.

Your Lordship's Memorialists, therefore, humbly pray that Her Majesty's Government will take steps during the next Session of Parliament to have the existing law amended in these respects.

JAMES MOLONY, President.

JOHN H. CHAPMAN, Hon. Sec.

Irish Medical Association.

FEES TO MEDICAL WITNESSES.

In the last report of the proceedings of the Committee of Council (pp. 134-6), the scale of fees payable to medical witnesses in civil cases, fixed by an order in Council, made at Dublin Castle, on the 26th June, 1882, was quoted, and reference made to its inadequacy.

The Committee of Council brought the subject under the notice of the King and Queen's College of Physicians and the Royal College of Surgeons, which resulted in a conference of representatives of the three corporations being held at the College of Physicians, when a form of Memorial for presentation to His Excellency the Lord Lieutenant was agreed upon, praying that the scale might be amended in the interest of the public as well as of the medical profession.

The Committee of Council have proposed some alterations in the draft memorial, which is still under the consideration of the Colleges; and it is expected that a memorial similar in purport will soon be finally agreed upon for early presentation.

THE CASE OF DR. O'REILLY (LISMORE).

Relative to the enforced retirement of Dr. O'Reilly from his appointment as medical officer of Lismore Union Workhouse (referred to in last report, pp. 141-144), the Committee of Council remonstrated with the Local Government Board touching the extraordinary ill treatment which that gentleman appears to have suffered, and regarding the possible effect the action of the Local Government Board in that instance might have upon the position and tenure of appointment of Poor-law medical officers as a precedent if allowed to pass unchallenged.

The following is the correspondence:-

Irish Medical Association,
Royal College of Surgeons,
October 20th, 1882.

To B. Banks, Esq., Secretary of Local Government Board.

SIR,—The attention of the Council of the Irish Medical Association has been directed to the circumstances attending the recent resignation by Dr. O'Reilly of his appointment as medical officer of the Lismore union workhouse. The Council has learned that, in consequence of an altercation in which the medical officer, the nurse, and the master were involved, the Local Government Board considered it expedient to hold an investigation into the circumstances, and that, on the report of that inquiry being transmitted to the board of guardians, it was resolved by them that the nurse and the master should be reprimanded, but that the medical officer should be called upon to resign. It has been further stated to the Council that, upon this resolution coming to its notice, the Local Government Board communicated to the guardians its opinion that the conduct of the medical officer did not merit a more severe punishment than that awarded to the other officers. But, nevertheless, the Local Government Board subsequently officially notified to the guardians that, if they desired to suspend the officer, no objection would be offered by the Board to their doing so.

Upon this expression of opinion the board of guardians reiterated its intention to obtain the removal of the medical officer, and called upon him to resign, and, as he hesitated to comply with this order, notice was given of the discussion of a proposal to suspend the medical officer from the performance of his duties.

the walls. There was considerable disorganisation of the tricuspid valve, permitting free regurgitation; the other valves of the heart were thin, but competent. This case is of much interest, and will form the subject of a report by a committee appointed by the Pathological Society of Philadelphia.

Epidemic Cholera in Egypt.

AN official announcement is made to the effect that an epidemic of cholera has broken out at Damietta, in Egypt, nineteen deaths having taken place within a brief time after the first case was noticed. A sanitary cordon has been established by sea and land around the afflicted city, and a medical commission has been despatched from Cairo to the scene of the outbreak.

Proxy Voting at the Royal College of Surgeons of England.

THE annual election of members of Council at the Royal College of Surgeons of England has this year assumed a special importance from the importation of a "burning question" into the discussion on merits, in the shape of proxy voting. It is impossible to avoid a conviction of the justice of the demand now formulated by a large proportion of Fellows of the College, who naturally feel aggrieved at the disadvantages country residents have to contend against as compared with those who live in town, and are thus enabled at little expense or inconvenience to record their votes personally. "The Association of Fellows of the Royal College of Surgeons of England" has set itself diligently to secure the desired amendment of rules in respect to voting, and if as the result of their endeavours candidates shall be returned to the Council pledged to support an agitation for removal of the existing disabilities of non-resident electors, it will be a source of genuine satisfaction to a very considerable number of those who are warmly interested in the welfare of the College itself.

St. Thomas's Hospital.

ON Saturday last the Duke of Connaught, accompanied by the Duchess, distributed the prizes at St. Thomas's Hospital Medical School, and addressed the students in terms eulogistic of the profession they had chosen, and of the work they had accomplished. His Royal Highness spoke in evident appreciation of the subject of his speech, and evinced a warm interest in the arrangement of the hospital, over which he and the Duchess of Connaught were conducted subsequent to the formal ceremony. The following prizes were awarded:—H. Duncan, an entrance scholarship of £100 and certificate of honour; E. D. Shirliff, entrance scholarship of £60 and certificate of honour; the William Tite first year's students' scholarship was gained by H. P. Hawkins (Hawkhurst); the Musgrove second year's students' scholarship of 40 guineas was divided between S. H. Jones and K. Totsuka (Japan), both being equal; and the Solly medal and prize of £25 by W. A. Duncan.

H.R.H. THE PRINCESS CHRISTIAN will open the new wing of the North West London Hospital (the "Helena" Wing) on Tuesday next, July 3rd.

Naphthaline as a Surgical Dressing.

DR. HAGER, of Hamburg, has reported, in the *Centralblatt f. Chirurgie*, the results obtained by him in the employment of naphthaline powder as a surgical dressing. As he has been perfectly satisfied with the antiseptic qualities of corrosive sublimate and its preparations, the bandages, &c., made use of were rendered antiseptic by means of it, and the naphthaline was therefore used only as a powder. It was only employed in extensive ulcers of the legs, or in such as resulted from incision of phlegmons and scrofulous glands as a cheap and agreeable permanent dressing. The mode of employment was as follows:—The wounds were first cleansed with solution of corrosive sublimate, and then covered with a layer of powdered naphthaline 1 to 2 ctm. thick. This was secured in its place by a suitable bandage. The dressing was not changed until moisture showed through, which happened at periods varying from 2 to 24 days. The subsequent dressings were like the first, except that the corrosive sublimate solution was only dropped on after the first. The author concludes that naphthaline forms an excellent dressing for such extensive flat ulcers; a number of them healed under one dressing, from the firm cicatrices of which the naphthaline could be raised in the form of a thin, coherent, lightly-sitting cake. The majority of the wounds healed under the second dressing either completely or to such an extent that only a small well-granulating sore remained, that closed up easily under sticking-plaster compress. As might be expected, the very large ulcers were longer in healing, but even in these the advantages of the dressing were evident, both as a preventive of decomposition and as assisting the formation of healthy granulations. Dr. Hager observed none of the objectionable effects of naphthaline that have been mentioned by some observers, except a strong tarry odour, and sometimes severe pains that remained, however, no longer than two days, and exercised no injurious influence over the healing processes.

Dr. Arnold Spina.

THIS gentleman, until quite recently unknown, or known only to a few as an intelligent and active assistant in Professor Stricker's laboratory in Vienna, and who has made himself famous by a sturdy and determined resistance to the doctrine taught by R. Koch, has not been labouring in vain. It would be going too far to say that Vienna is jealous of Berlin, but we are not assuming too much when we say that the bacillus *Krieg* carried on by the part of Spina with no little acumen and a more thorough knowledge of the subject than he has received credit for from his opponent, has, to say the least, not been displeasing to those in authority. This is shown by the offer he has received of the post of Ordinary Professor of General and Experimental Pathology in the Czechish Faculty of Medicine in the University of Prague—an offer which has been accepted. Shall we now have to endure the woes of another Battle of Prague? In commenting on this appointment, the editor of the *Allgemeine Wiener Medizinische Zeitung*, Dr. B. Kraus, remarks that "the most striking thing in the whole affair is certainly the circumstance that it is precisely the bacillus question which gave Spina the opportunity to *documentiren* his

learning in the whole range of general pathology and histology that has assisted him to this honour. . . . The Czechish University is now a *fait accompli*; the Ministry seeks after the best powers, and it is certainly desirable that they should be taken from the Vienna School, in order that microscopy and histology, in whatever language they may be taught, may produce disciples who will not at once inscribe upon their standards, '*Jurare in verba magistri*,' but who will have the courage to attack with their criticisms even the discoveries of the German Imperial Health Office and their Köchen."

The Albert Medal.

THE Albert Medal conferred each year by the Society of Arts for distinguished merit in promoting arts, manufactures, or commerce, has just been awarded to the eminent botanist and Director of the Royal Gardens at Kew, Sir Joseph Dalton Hooker. This will be generally regarded as a most appropriate bestowal of the medal, which is well merited by Sir Joseph Hooker, if only by reason of his services in connection with plant cultivation in so far as medicinal drugs are concerned. To him, moreover, the various colonies and dependencies of our Empire are in no small degree indebted for much of their present welfare; and as a practical botanist and writer on botanical subjects he has made for himself a name which is second to that of no other authority. The Society of Arts is to be congratulated on having made a most fitting selection.

The Parkes Museum.

MR. MARK H. JUDGE, A.R.I.B.A., has resigned his position of Secretary and Curator of the Parkes Museum. At a special meeting of the Council on June 15, Captain Douglas Galton, C.B., in the chair, the following letter was read:—

"To Captain Douglas Galton, C.B., D.C.L., F.R.S., and the other Members of the Council of the Parkes Museum.

"Gentlemen,—It is with regret that I inform you that I feel compelled to resign the position which I have held so long in connection with the Parkes Museum of Hygiene. Now that the Museum has been incorporated and established in a building of its own, with its collection and library open to the public daily, I can no longer give the necessary time and attention that the interests of the Museum will henceforward demand from the Secretary and Curator. Since my appointment in 1878 until the present time it has been my great desire to do all in my power to aid you in your work of establishing in this country a National Museum of Hygiene, and I shall be happy to continue my services as Secretary and Curator till you are able to appoint my successor. I need hardly say that as a member of the Museum I shall always take the warmest interest in its success, and be ready at all times, as far as I can, to promote its welfare.

"I am, Gentlemen,

"Yours faithfully,

"MARK H. JUDGE."

The following resolution was unanimously passed:—

"The Council learn with great regret that Mr. Judge is compelled by his professional engagements to retire from the position of Secretary and Curator of the Parkes Museum. In accepting Mr. Judge's resignation the Council desire to place on record their high appreciation of the services which he has rendered to the Museum."

DR. WEBB KELLY, in the *Columbus Medical Journal*, reports a number of cases of carbolic acid poisoning by the constant use of injections of carbolised water by women to prevent conception. He says cases of this kind are of daily occurrence in American practice, where the constant use of this agent produces a mild form of poisoning, great nervous prostration, and irritability of the parts affected. Withdrawal from connubial intercourse for a time, and the consequent carbolised injections, in most cases resulted in the re-establishment of health.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official returns, as follow:—Calcutta 36, Bombay 28, Madras 34, Paris 27, Geneva 19, Brussels 26, Amsterdam 26, Rotterdam 23, The Hague 21, Copenhagen 21, Stockholm 22, Christiania 13, St. Petersburg 33, Berlin 27, Hamburg 28, Dresden 25, Breslau 38, Munich 33, Vienna 32, Prague 45, Buda-Pesth 31, Venice 22, Lisbon 32, New York 29, Brooklyn 20, Philadelphia 21, Baltimore 19.

THE highest annual death-rates from diseases of the zymotic class in the large towns were—from measles, 1·9 in Liverpool and 2·8 in Newcastle-upon-Tyne; from whooping-cough, 1·2 in Manchester and in Cardiff, and 1·4 in Plymouth; from scarlet fever, 1·9 in Sheffield and 2·0 in Wolverhampton; and from "fever," 2·0 in Portsmouth. The zymotic death-rate in Glasgow reaches to 8·2 of the entire mortality. The 27 deaths from diphtheria in the large towns included 15 in London and 5 in Glasgow. Small-pox caused 3 deaths in London, one in Newcastle-upon-Tyne, and one in Hull.

Scotland.

[FROM OUR NORTHERN CORRESPONDENTS.]

"RISING TO EMINENCE IN HIS PROFESSION."—An important case has just been tried at Glasgow, under "the Food and Drugs Act," resulting in the imposition of a substantial fine on a Glasgow druggist. There are many and most diversified ways of "rising to eminence" in the medical profession, not a few of them of a reprehensible nature, and among these are to be classed the weakness which yields to the employment of every new drug with which the advertising columns of our medical journals and trade circulars make the profession acquainted. The motives which lead to this are doubtless mixed. On the one hand, care is often taken solemnly to inform the patient that the new prescription is known only to few, that its virtues are surprising in their efficacy, the chase in quest of the drug from shop to shop gives additional zest, and the prescriber is consequently vulgarly glorified. On the other hand, many estimable men give way to the blandishments of the advertising column from a genuine desire to benefit their patients and a Utopian credulity which, while it reflects generously on them, is somewhat refreshing in these latter days. In the eyes of sensible people there is nothing more incomprehensible than the ever-changing methods of cure and the kaleidoscopic existence of given drugs. They naturally wonder how in any science the cures of the one generation happen to become the poisons of the next; and not without reason they begin to doubt whether medicine is

anything but complete charlatanism. We cannot here enter into a detailed examination of this question; but we express our opinion briefly that much of this arises from, so far as the science of medicine is concerned, a disloyal sycophancy to the public in indulging in the matter of drugs their insensate craving for novelty. We leave out of the question for the present the inability to observe, and unconscious self-delusion. Mr. Bright recently stated that he felt inclined to ask every American on his first interview with him whether he possessed a patent. Medical men might specially ask whether he possessed a new medicine, and not improbably a patent one. This is one direction, at all events, in which Western Liberty has produced pernicious results. America is the country *par excellence* of drugs patent and non-patent, and for the past few years a large number of such drugs, some possibly useful, but the majority of them, if not inert, at least useless, have found their way into British medical trade, thanks to the power of "puffing" and the simplicity of the average "man of science." It is one of these drugs, it would appear, that Dr. Carmichael prescribed. He seems to have been "the only medical man in Glasgow" who had attained to the knowledge of its virtues; and surely under all the circumstances it would not be a matter of surprise if a chemist should think "methyl salicylatis" might be but another name for one of the salicylates frequently employed. Be the technical legal bearings what they may, it ought to be consolation to the patient that we believe him to have fared as well with-out as with this trash, commonly known as "winter green." In the end, Mr. Sheriff Balfour imposed a penalty of £4, without expenses, remarking that it was perfectly clear that the chemist should have sent to Dr. Carmichael to ascertain what the drug was, and where it was to be obtained, instead of assuming that it was another name for a familiar drug.

MEDICAL ACTS AMENDMENT BILL AND ST. ANDREWS UNIVERSITY.—In connection with the address by Professor Leishman, on which we commented in our last impression, Dr. Bell Pettigrew, Dean of the Medical Faculty of the University of St. Andrews writes as follows:—"Dr. Leishman is quite entitled to state his own argument in his own language, even if that language is deficient in the dignified reserve with which the professor in one university should speak of the position and work of another university, of which he plainly knows very little; but he is not entitled to make remarks and to insinuate motives calculated to misrepresent the position of a sister university. He first of all makes the general statement that, in relation to the Medical Acts Amendment Bill, 'St. Andrews had no interest whatever in common with the other universities.' This may be Dr. Leishman's opinion, but it is not the opinion of the University of St. Andrews; and St. Andrews probably knows its own interest as well, or better, than Dr. Leishman. He further states that 'during the last ten years St. Andrews had placed five men on the Medical Register,' and asks, 'Was that a position entitling any representative body to be a member of the Divisional Board?' It is right the public should know that, during the period in question, St. Andrews University has made one hundred and ten doctors of medicine, and that its claim to a seat on the Medical Board is undoubted. Dr. Leishman further asserts 'that for the examination of those few students St. Andrews had to go to the corporations of Edinburgh, and was allied with them in the conducting of examinations.' Now, nothing can be further from the truth. The University of St. Andrews is

in no way allied with the corporations of Edinburgh in conducting its examinations. It has its own professorial examiners, and it is free to choose its non-professorial examiners wherever it finds able and suitable men. In this respect St. Andrews is on the same footing with the other Scotch universities. Dr. Matthews Duncan, of London, Dr. Handyside, of Edinburgh, Professors Gairdner and Buchanan, of Glasgow, and Professor Struthers, of Aberdeen, have all been examiners at St. Andrews. Dr. Leishman proceeds as follows:—"They did not believe for a moment that they could on any subject where it was corporation *versus* university count upon the vote of St. Andrews, although in the Bill it was called a university vote." "The strongest proof he could give of the sincerity of his belief as to this was to say that he would be glad to make a present of that vote to the corporations to-morrow." It is quite clear that no one can (by any stretch of courtesy) be entitled to make statements of this nature. The vote of St. Andrews, there is no room to doubt, will be given in the interests of right and justice as certainly as the two votes of Glasgow, and it is unbecoming even to hint at anything else. Dr. Leishman has had the bad taste to endeavour to elevate the Universities of Edinburgh, Glasgow, and Aberdeen by depressing and undervaluing the University of St. Andrews, the oldest, and in some respects the most celebrated, of all the Scottish universities, and, as your readers will perceive, he has not succeeded in making out a good case."

EDINBURGH.—HEALTH OF THE CITY.—For the week ending with Saturday, the 16th inst., the mortality in Edinburgh was 72 and the death-rate 16 per 1,000. There were 23 deaths under 1 year, and 16 above 60, of which 3 were above 80 years. Diseases of the chest accounted for 42 deaths and zymotic causes for 8, of which 2 were due to fever, and 5 to measles, the intimations of these diseases for the week being 8 and 66.

REMARKABLE LONGEVITY IN ISLAY.—A short time ago there was interred in Kilchunan, Islay, the remains of Mrs. Euphemia MacKenzie, who died at the age of 105 years, having been born in May, 1778. With the exception of her last illness she was only once confined to the house, and that but for a few days with a sore foot, and her last illness lasted only three months. Up to the time of her death she was in possession of all her faculties, and chatted freely with her relatives upon local and family matters.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 16th inst., were at the rate of 30 per 1,000 per annum, against 34 in the preceding week, and 23, 26, and 25 in the corresponding periods of 1882, 1881, and 1880.

A NEW HOSPITAL FOR CROSSHILL.—By the will of the late Mr. Robert Couper, paper-maker, Cathcart, he has bequeathed the residue of his fortune, after providing for other charitable institutions, for the building of a hospital and convalescent home in or near Crosshill for the use of the district south of the Clyde. His trustees are directed to proceed with the erection of the infirmary or hospital as soon after his death as they find that the funds at their disposal are sufficient for the purpose, and they are especially empowered to accept as donations for the purpose of the bequest any sums which may unconditionally be given to them, or be bequeathed to them, for that purpose. Doubtless Dr. Duncan's scheme will become amalgamated in some manner or other with this one.

AN OVERDOSE OF LAUDANUM.—An engineer named William Henderson died on the 21st inst., at Glasgow, from the effects of an overdose of laudanum. He resided at 39 Tobago

Street, and reached his lodgings late the previous night, and was found lying on the floor of his bedroom in an unconscious state. A bottle in which there had been landanum was lying at his side. Dr. Downie was at once sent for, but the man never rallied, and died within an hour.

Literature.

KREUZNACH AND ITS OZONE. (a)

In this little pamphlet Dr. Stabel gives us first some account of ozone, then the results of 83 days' continuous measurements of the ozone of Kreuznach, and lastly, a very short notice of the supposed therapeutical effects of this form of oxygen. The first and last subjects we shall not discuss. Notwithstanding the fact that so little is really known about the therapeutical value of ozone, there is a very general impression abroad that its presence in the atmosphere is somehow or other a thing to be desired. As a good supply of oxygen is known to be necessary to animal well-being, so the presence of ozone—an unusually active form of oxygen—is looked upon as something, perhaps, still more devoutly to be wished for. So deeply rooted is the belief in the therapeutical importance of ozone that many places, health resorts especially, have laid claim to the honour of having in their surrounding atmosphere the greatest known quantity of it.

Kreuznach has now entered the list in the contest, and the published report shows that, although there does not seem to be much ozone naturally in the locality, visitors can be supplied with a not inconsiderable quantity.

Schönbein's method of measurement was the one employed by Dr. Stabel, and the test papers were exposed in the usual manner continuously in three different places, and the results accurately recorded. Two sets of papers were exposed in the Inhalatorium—a long narrow hall, within which the process of concentration of the saline waters was continually being carried on; two more were exposed on the outside walls of this building; and, finally, one set at the observer's own residence.

A study of these tables is extremely interesting, and leads to important conclusions. The observations were commenced on July 1st, 1882, and were continued without interruption up to September 21st—a period of 83 days. Within this period there were 42 wet and 41 fine days.

The average quantity of ozone per day of 11 hours—7 a.m. to 6 p.m.—according to Schönbein's scale during the 42 wet days, was—

Within the Inhalatorium	4.46 deg.
Outside	3.55 "
At observer's residence...	1.02 "

The average quantity on the 41 fine days was—			
Within Inhalatorium	3.47 deg.
Outside	2.84 "
At observer's residence...	1.09 "

The night quantities during the above period, calculating for different lengths of exposure, were, during the 42 wet days—

In Inhalatorium...	4.28 deg.
Outside	4.02 "
At observer's residence...	1.54 "

During the 41 fine nights the results were—			
In Inhalatorium...	2.39 deg.
Outside	2.63 "
At observer's residence...53 "

These averages are made up of the most varied and capricious daily measurements. At present it is difficult or impossible to estimate their value. The most that can be affirmed is that within the Inhalatorium and in its vicinity outside, when the process of concentrating the saline waters is going on, Schönbein's test-papers register the presence of a considerable quantity of ozone; that they register its presence at the observer's residence, but in far less quantities.

It would have been better if the test-papers had been exposed in that stratum of atmosphere in which respiration by human beings takes place, and not at the height of

9 and 3 metres from the earth's surface. Measurement at this height is no test of the quantity present at 5 feet from the earth's surface.

As we do not habitually walk on stilts or in raised galleries for the purpose of inspiring the increased quantities of ozone of these exalted strata, it would have been better to let us know the quantities at altitudes of 5 feet and under—that is, in the strata in which respiration is performed by ordinary people under ordinary conditions.

EXAMINATION OF THE CHEST. (a)

THIS is a practical guide for students, which is likely to be successful. It is illustrated with a number of diagrams, and arranged in a manner to impress the learner. As a medical tutor, Dr. West has had the opportunity of observing the wants of students, and in this little manual he has supplied one of them. It is not necessary to endorse every statement he makes in expressing this approval, or we might stop to say that insurance companies would scarcely accept some of the measurements he has given as healthy. The book is divided into four sections, treating respectively of the lungs, heart, pulse, and mediastinum. In some portions it is very brief, but on the whole it is, perhaps, sufficient, and certainly is a handy and concise manual.

Correspondence.

TREATMENT OF FRACTURES OF THE PATELLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Some weeks ago there appeared in your journal a series of articles by Mr. H. O. Thomas upon the "Treatment of Fractures of the Patella;" and again this week you publish a case treated by Mr. Henry Parson which illustrates a much older method of procedure. Mr. Thomas's method involves complete fixation of the knee until the bond of union between the fractured portions of the patella is sound and consequently unyielding. Mr. Parson's splint permits of "slight movement of knee while walking," a very grave defect, and one that calls for a little attention. The essentials of Mr. Thomas's apparatus consist of two parallel iron rods, terminating at one end in the heel of the patient's boot, and at the other in a nicely fitting perineal ring surrounding the uppermost portion of the thigh. A blacksmith can make it in a day with a saddle to help, and their combined labour would scarcely realise ten shillings. A roll of soaked cotton-wool above and one below the patella and a strip of plaster to bring pressure, together with a bandage, completes the plan, by which the broken bone can be admirably controlled. With the splint on, the patient has no power of flexion in the knee, but full freedom in the hip. Mr. Parson describes his splint in your last number, and adduces five arguments on its behalf. They embody the propositions that long confinement to bed is avoided; the keeping of fragments in good position; the security (?) against ankylosis by permitting during treatment of slight movement of joint; and the maintenance of "activity in the parts, to complete union."

If movement be permitted to the knee-joint during treatment it must of necessity be at the expense of immobility at the seat of fracture, the extent of harm being commensurate with the range of motion. In the particular case reported movement was not attempted until the fifth week; but this I take to be accidental, as Mr. Parson lays down the rule that "as soon as the primary inflammation has subsided . . . the patient can begin to move about." The term "primary inflammation" is vague; but if it means the synovitis with or without effusion so often present, a few days will generally suffice to overcome it. Should the patient, however, not commence to walk until imperfect union has occurred, Mr. Parson urges that movement of the fractured ends will produce "sufficient activity in the parts to complete the union." This is contrary to usage, and I venture to say, experience. We have only to inquire into the causes of non-union of other bones to find that consolidation is often absent where motion has been summoned too early. Fracture of the patella demands rest no less than other fractures, and, as Mr. Thomas has pointed out, one of the pregnant causes of defective cure in this very

^a "Das Ozon und seine mögliche therapeutische Bedeutung." Dr. Eduard Stabel, Reinhard Schmidthals, Kreuznach.

(a) "How to Examine the Chest." By Samuel West, M.D. London: J. and A. Churchill. 1883.

injury is flexion of the knee before the patella is quite sound. This is proved by every-day experience. How often we find cases discharged from hospital after two, three, and four months' sojourn where patellar union seems all but perfect, and yet a very few weeks of free use of the limb, with or without knee-cap, is sufficient to make both the surgeon and patella gape. Previous treatment cannot be blamed for it, but the surgeon may be justly censured for permitting movement where its evil result is manifest. In Mr. Parson's case the result does not wholly justify the means, for we have abundant proof of the recovery of many patients from similar injuries left to the tender mercies of sea captains. Isolated cases of good results will occur whatever the treatment; the danger lies in the confusion of the "propter" with the "post hoc." Mr. Parson adds, "slight movement of knee in walking about prevents a stiff joint." This I emphatically deny, and the proof is contained in two propositions:—1st. Inflammation is a necessary precursor of ankylosis. 2nd. Inflammation is increased in a knee when moved. In a given case the worse the inflammation the greater the danger of ankylosis.

The advantages claimed for Thomas's method are freedom from confinement and efficiency of cure. With the splint on the patient is free to follow his out-door habits in a couple of days after his accident, and that without the slightest risk. The apparatus forms a convenient form of perineal crutch, which withholds all flexion at the knee. A few days back, at the Stanley Hospital, I removed a Thomas's splint off a corpulent old dame who had worn it five months. To-day movement at the knee was very fair; next week it will be nearly well. The fragments, which were two inches apart, are now in perfect apposition; but the method I adopted saved me from all apprehension from the first. Yesterday week I removed two splints which had been for two years correcting genu valgum, during the whole of which time no movement was permitted to the knee-joints. To-day movement is nearly perfect. This is only one of several instances. I have seen upwards of twenty cases of fractured patellæ treated by Thomas's method, and never yet a stiff joint resulting. To ensure permanency of cure it is often necessary to wear the splint six months, and patients rarely complain of discomfort meanwhile.

I am, &c.,

ROBERT JONES,
Senior Assistant Surgeon,
Stanley Hospital.

22 St. George Square,
Liverpool, June 21.

THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your journal of June 13th and 20th you gave great prominence to the false statement of Mr. A. Conan Doyle, M.B., respecting the departure of diseased women from hospital in Plymouth. You appear not to have seen his acknowledgment that this statement was an error, or you would doubtless have given equal prominence to the contradiction.

Surely the solution of a grave social problem, involving the highest moral and physical welfare of our country, can never be attained by the spread of falsehood on either side! In judging this question, it would be well if every member of the profession would carefully read "Le Pêril Vénérien dans les Familles," by Dr. P. Diday (published by Asselin and Co., Paris). The perusal of this work, written by an experienced French surgeon, must arrest the attention of every unprejudiced Englishman. It shows the practical results which follow from working for several generations on a false principle.

This false principle (of which the author is a follower) is the refusal to check whoremongers, whilst endeavouring to regulate whores. The pitiful stultification of judgment which results from frantically endeavouring to establish this false principle is only equalled by the astounding cynicism which such a foolish contravention of law produces.

Both these results are strikingly shown by this and other lately published French medical treatises.

I am, Sir, yours, &c.,

A CONSTANT READER (but a believer in the oneness of medicine and morality.)

The following is the contradiction referred to:—

The Secretary of the National Association for the Repeal of the Contagious Diseases Acts, having had the letters of Mr. Doyle to *Daily Telegraph*, June 8th, and one from S. U.

Thompson, June 9th, brought to his notice, wrote to Mr. Doyle, pointing out that, as the Acts had not been repealed, and the compulsory detention in hospital had not been suspended, his "ounce of fact" was an evident fiction. Mr. Doyle replied: "I am glad that you have called my attention to my error as regards the dismissal of women from the hospital. I had the story from two members of the Visiting Committee, but Dr. Snowdon, the indoor officer, assures me that there is no foundation for it. I have, of course, written a contradiction of it to the paper."

Mr. Conan Doyle, M.B., C.M., of Portsmouth, writing in reference to the letter from him which was published in the *Daily Telegraph* of Friday last (June 8th), says: "I find that one error has crept into my statement of the increased immorality since the suspension of the Acts. It is not correct that thirty women left the hospital with the avowed intention of meeting a transport. The error arose from the misconception of some remarks made by a gentleman intimately connected with that institution." Mr. Doyle adds that this error in no way affects his general argument—"the difference in the streets of Portsmouth is most marked, and grows worse."—From the *Daily News*.

Novelties.

AN ELECTRICAL PHOTOPHORE.

At a recent meeting of the French Académie de Médecine, M. Dujardin-Beaume presented an electrical "photophore," invented by M. Paul Hélot, chief surgeon to the hospital at Rouen, and M. Trouvé. The apparatus consists of an

incandescent lamp contained in a metallic cylinder, between a reflector and a convergent lens. This small instrument when fastened on the forehead gives a very intense light, and can be adapted to the field of vision by moving the lens. When placed between the eyes, the light, as it were, accompanies the view of the operator, as there is nothing to interfere with it. The source of the electricity is a voltaic pile of bichromate of potash supersaturated. It lasts many hours without being re-charged, and can be used either continuously or at intervals. This apparatus will be found most useful in examinations of the mouth, throat, ears, &c.

AN IMPROVED NURSERY POWDER.

The importance of a pure, non-irritating, and innocuous nursery powder is so generally recognised by the profession and the public alike that the addition of a reliable article of this kind to those already in use is of some consideration. Messrs. Woolley, Sons, and Co., of Manchester, have introduced a new "sanitary rose powder," which is not inappropriately named "the perfection of nursery powders," and which possesses the unique and highly valuable property of being soluble in water, so that the annoyance produced by caking is altogether avoided by its use. The powder is also antiseptic, and is, in very many respects, a great improvement on those in general use. Its employment, in nurseries particularly, may be strongly recommended.

University of Durham.—The following satisfied the examiners for the M.D. degree for practitioners of fifteen years' standing :—

Coates, Matthew, F.R.C.S. | HU, M., M.R.C.P.E., F.R.C.S. Ed.
Gilbert, Ed. G., M.R.C.S., L.S.A. } Equal.

For the ordinary M.D. degree—

Callcott, James T., M.B., M.R.C.S. | Walker, B. W., M.B., M.R.C.S.,
L.S.A.

For the M.B. degree—

Second Class Honours (Order of Merit).

Rodman, George Hook, L.S.A. | Hutchinson, Joseph A. } Equal.
Frueo, S. T., M.R.C.S. }

Archer, Ed. L., M.R.C.S., L.S.A.

Brown, Richard.

Buxton, William Maberly.

Charpentier, Ambrose Ed. Lea.

Eastes, Frederick, M.R.C.S.

Henwick, Henry Marshall.

Hepworth, Arthur.

Morgan, Llewellyn Arthur.

Ridley, George Walter.

Tomson, Walter Bolton.

Wigan, Charles A., M.R.C.S.

At the above examinations for the M.D. degree there were three candidates: two satisfied the examiners and one was rejected. For the M.B. degree there were sixteen candidates: fourteen satisfied the examiners, one retired, and one was rejected. For the M.S. degree there were six candidates, all of whom were rejected.

Notices to Correspondents.

PROFESSOR HUTCHINSON'S LECTURES AT THE LONDON COLLEGE OF SURGEONS.

IN accordance with our annual custom, we propose presenting our readers with the complete course of lectures now being delivered at the Royal College of Surgeons of England by Professor Jonathan Hutchinson. The subject selected is "Diseases of the Tongue," the first lecture of which will be commenced with the new volume of the *Medical Press* next week.

MR. SAMPSON.—We are glad to learn the result of your endeavours. The addresses have been noted, and copies duly sent. Your letter arrived too late for acknowledgment last week.

DR. K. (Manchester).—Silk ligatures may be left in with perfect impunity. The records of many successful cases sufficiently demonstrate the safety of the proceeding. Mr. Lister's chromicised catgut can be prepared according to the directions given by him before the Clinical Society in 1881-82.

L. F.—The National Health Society's offices are at 44 Berners Street, Oxford Street, W. The secretary may be able to give you the information you require. We do not know the particulars of entry.

SURGICUS.—You may find an opportunity of describing your invention before one of the Societies. You had better communicate with, say, the Secretary of the Medico-Chirurgical.

DR. F. JOHNSON.—There is nothing in the measure to provoke the criticism you have expressed, nor as it stands at present can it be said to possess the serious shortcomings you have described as its faults. The stringent recommendations you suggest would, if insisted on, preclude all possibility of its successful passage.

MR. NEWSOM.—No case has been recorded in this country of more recent date than that you refer to as having appeared in our columns at the beginning of the present year.

PROPOSED INTERNATIONAL MEDICAL AND SANITARY EXHIBITION AT NICE.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—Following the example of many other cities, the Mayor and Municipality of Nice have resolved on opening an International Exhibition there in December next.

The Society of Medicine at once seized the opportunity to point out the importance of devoting a portion of the building to a Medical and Sanitary Exhibition, and you will see by the enclosed catalogue how earnestly they seek that it shall be as complete and as practically useful as possible.

All of us who have lived on the Continent know how far from perfect are the hygienic and sanitary arrangements of our neighbours on the other side of the Channel; and the Riviera has had in these respects more than its fair share of blame.

If you, Sir, and other members of the profession will lend your influence and help to promote its success, the Medical and Sanitary Exhibition at Nice may be the commencement of far better things than exist at present, and we may then send our patients to the South in search of health with none of those misgivings as to imperfect drainage, untrapped closets, and ill-ventilated houses, which make us sometimes hesitate as to whether an English winter with its damp and cold and darkness may not after all be safer than the cloudless sky and brilliant sunshine of the Mediterranean.

The London agents are Messrs. Johnson, Castle St., Holborn, E.C., to whom all applications for space must be addressed, and from whom all information may be obtained.

I shall also be happy to answer any inquiries on the subject.

I am, Sir, yours faithfully,

3 Bolton Row, May Fair, W., CHARLES WEST.
June 11, 1883.

ARCHIBALD E.—The meaning is sufficiently obvious. The mistake arose from absence of proof revision, and has been a subject of much regret.

DR. DRYSDALE.—The report of M. Flaux to the Paris Council shall appear in an early number.

DR. TAYLOR (Nottingham) will find Mr. Doyle's correction referred to by another correspondent in present issue.

Vacancies.

Bath, Eastern Dispensary.—Resident Medical Officer. Salary, £100, with extras. Applications to the Hon. Sec. before July 2nd.

Bradford.—Medical Officer of Health to the Corporation. Salary, £500. Immediate application to the Chairman of the Sanitary Committee.

Brompton Consumption Hospital.—Assistant Physician on the Staff. Candidates must send in their applications, &c., before July 11th. (See advt.)

Huddersfield Infirmary.—House Surgeon and an Assistant House Surgeon. Salary, £80 and £40 respectively, with board. Applications to the Hon. Sec. before July 6th.

Manchester Royal Infirmary.—Medical Officer for the Convalescent Hospital at Cheadle. Salary, £150, with board. Applications to the Secretary before July 4th.

Royal Hants County Hospital, Winchester.—House-Surgeon. Salary, £10, with board. Applications to the Secretary before July 4th.

St. Mary's Hospital, Paddington.—Demonstrator of Physiology. Value of appointment, £100 per annum. Applications to the Dean before July 7th.

Stockton-on-Tees Hospital.—House Surgeon, non-resident. Salary, £200. Applications to the Secretary before July 14th.

Sunderland Infirmary.—Second House Surgeon. Salary, £60, with board. Applications to the Chairman of the Medical Board before July 3rd.

Appointments.

CAIGER, F. F., M.R.C.S., L.R.C.P. Lond., Resident Accoucheur to St. Thomas's Hospital.

CHADWICK, C. M., M.A., M.B. Oxon., House Physician to the London Hospital.

CLARKE, E., M.B., B.S., Assistant Surgeon to the Central London Ophthalmic Hospital.

COLMER, P. S. H., L.R.C.P. Ed., L.F.P.S. Glas., Medical Officer for the No. 2 Dist. of the Yeovil Union.

FELL, W., M.A., M.B. Oxon., M.R.C.S., L.R.C.P., House Physician to St. Thomas's Hospital.

HAIQ-BROWN, B., M.B., C.M. Aberd., M.R.C.S., House Physician to St. Thomas's Hospital.

HERRINGHAM, W. P., M.B., M.R.C.P., a Casualty Physician to St. Bartholomew's Hospital.

HULL, W., M.R.C.S., L.R.C.P., Assistant House Physician to St. Thomas's Hospital.

JONES, W. W., M.A. & M.B. Oxon., B.Sc. Lond., M.R.C.S., Assistant House Surgeon to St. Thomas's Hospital.

MARLOW, F. W., M.R.C.S., Ophthalmic Assistant to St. Thomas's Hospital.

MARSHALL, J. G., B.A., M.B. Cantab., M.R.C.S., House Surgeon to the Doncaster Infirmary.

MILTON, H. M., M.R.C.S., House Surgeon to St. Thomas's Hospital.

OWEN, I., M.D. Cantab., Assistant Physician to St. George's Hospital.

Births.

STEVENSON.—June 20, at 147 Camberwell Grove, Denmark Hill, the wife of Leader Stevenson, M.D. of a son.

THOMSON.—June 19, at Albemarle Street, W., the wife of J. Roberts Thomson, M.D., of Bournemouth, of a son.

Marriages.

PAULLEY-FISHER.—June 21, at Holy Trinity Church, Upper Chelsea, Legge Paulley, L.R.C.P. Ed., to Mary Elizabeth, only daughter of John Fisher, of 60 Cadogan Place, London.

SHAW-GRAHAM.—June 21, at Glasgow, Doyle Money Shaw, C.B., Deputy Inspector General of Hospitals and Fleets, to Jessie Martin, daughter of John Graham, Esq., of Inverleury, Callander, Perthshire.

Deaths.

BENNETT.—June 14, at his residence, St. John's Wood, William R. Bennett, M.D., Fleet Surgeon, Royal Navy, aged 47.

BROOKS.—June 19, at Henley-on-Thames, Arthur D'Oyley Brooks, M.R.C.S.

CHIAPPINI.—May 20, at Cape Town, Cape of Good Hope, Antonio Lorenzo Chiappini, M.D., M.R.C.S.E., aged 42.

GUNNING.—June 13, at Tooting, John Edmund Gunning, M.R.C.S., aged 43.

MCCRERY.—May 16, at Fort Station Hospital, Allahabad, suddenly, Surgeon-Major James McCrery, A.M.D.

PAYNTER.—June 19, at The Croft, Tenby, J. Paynter, C.B., M.D., J.P., Inspector General, A.M.D.

SHARPE.—June 19, at his residence, Lower Norwood, Alexander Barclay Sharpe, M.D., M.R.C.S., aged 53.

SULLIVAN.—June 9, after a long illness, at his residence, Elsham Road, Kensington, J. L. Sullivan, M.D., M.R.C.P. Lond.

WHITLEY.—June 14, suddenly, at Aix-les-Bains, George B. Whitley, M.D. Ed., Cannes, aged 75.

WILLIAMS.—June 22, at 21 Compton Road, London, N., Patrick St. George Williams, M.R.C.S.E., son of the late Dr. St. George Williams, Indian Medical Service.

IRISH POOR-LAW INTELLIGENCE.

CORONER FOR SLIGO.

A MEETING was held last week in the County Court House for the purpose of totting-up the poll-books in connection with a recently contested election for the office of County Coroner. Notwithstanding the passing of the Ballot Act, the voting was open. The candidates were Dr. Maloney, of Colloony, and Dr. Robert Roe, of Carney. As both gentlemen were of the same opinion in politics and religion, there was not much excitement. The result of the voting was as follows:—

For Dr. Maloney	416
For Dr. Roe... ..	354
Majority	62

BOYLE DISTRICT.

THE Coronership for Boyle (co. Roscommon) has also become vacant by the demise of Mr. Peyton Grevisk, who discharged the duties of the office for a number of years. The salary attached is £13 12s. per annum, with an allowance for mileage. The election is similar to a Parliamentary one, and the persons who possess the franchise for a member of Parliament are entitled to vote for a coroner. The election need not necessarily be held until after the Spring Assizes, but if two magistrates present a requisition to the Lord-Lieutenant the election can take place. Several candidates are named as being likely to seek the suffrages of the electors.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

(Continued).

Dr. JACOB'S examination continued.

777. You think that the Local Government Board have erroneously strained the law to the disadvantage of the medical officer?—I do not lay the blame upon the Local Government Board.

778. Upon whom do you lay the blame?—The fault is in the misconception of the rule, which obliges a month's notice to be given to the guardians.

779. Have you applied to the Local Government Board to correct that misapprehension of the month's notice?—No.

780. Would it in your opinion be desirable?—Yes, I think so. I think if there is a misapprehension, it should be open to the Local Government Board to remove it.

781. But you have never made application to them to remove it?—No.

782. Though it is a glaring injustice?—Yes.

783. You have had great experience of the Local Government Board; have you ever had any cause to complain of the arbitrary power of dismissing vested in the Local Government Board?—Yes.

784. When?—I complained very strongly of the action of the Local Government Board in dismissing Dr. Kenny from his position.

785. Was it a professional dismissal?—No, it was a dismissal for other reasons.

786. Was it not a dismissal openly and avowedly for political reasons?—It certainly had the appearance of it.

787. Have you ever known as gross a case of injustice perpetrated by any board of guardians as was perpetrated upon a member of your profession by the Local Government Board?—I think it was a very great injustice.

788. A gross case?—Yes, I think it was a gross case.

796. Notwithstanding that you have never known of as gross a case of injustice perpetrated upon a medical officer by a board of guardians as was perpetrated in the case of Dr. Kenny by the Local Government Board, you are yet in favour of giving discretion to the Local Government Board and refusing it to the poor-law guardians?—I did not say that I had never known as gross a case; I said it was a gross case.

797. Have you ever heard of so gross a case?—Yes, I have heard of them.

798. Will you give me an instance?—I know a case of a man who has been called upon to resign by a board of guardians within the last three weeks after a long period of service, during which his efficiency had not been challenged in any way, simply because he got into a squabble with a nurse, and had an abusing match with her.

799. Mr. Healy. Was that the case of Dr. O'Reilly?—Yes.

800. Do you allege that he was hardly dealt with on the part of the board of guardians?—Yes; I say that the board of guardians ought not to have called on him to resign, and ought not to have been allowed to insist on his resignation.

801. Does not your remark imply a reflection upon the Local Government Board?—It does imply, and I intend it to imply, a reflection upon them, as not having prevented the board of guardians from doing that injustice.

802. You give an expression of that opinion *ex parte* before this Committee when you know it involves an allegation that the Local Government have assented to an injustice?—In this particular case it was an injustice, and the Local Government Board did assent to it, and having already expressed the opinion that this gentleman was hardly dealt with, the Local Government Board ought to have refused to allow the board of guardians to do that injustice.

803. Mr. Biggar. Did the board of guardians dismiss the officer?—They called upon him to resign, they did not dismiss him; they have no power to dismiss at all, and I have reason to know that it was practically dismissal, because the gentleman would not have resigned, only he was compelled.

804. Mr. Healy. Though he was dismissed by the board of guardians, did not he retain his office in the dispensary?—Yes.

805. He was not dismissed entirely?—He was dismissed from one office.

806. Therefore the board of guardians did not dismiss him altogether?—The guardians called upon him to resign the workhouse.

807. They still allowed him to continue in the dispensary?—Yes, the question of the dispensary did not arise at all.

808. Mr. Callan. Then in point of fact the board of guardians did not dismiss him?—They had no power to dismiss him, they called upon him to resign.

809. They did not call upon the Local Government Board to dismiss him?—They did not call upon the Local Government Board to dismiss him; his resignation relieved them from such necessity, they did not have occasion to call upon the Local Government Board.

810. Is it customary in all cases in Ireland, except in very gross cases of immoral conduct, to call upon the medical officer to resign, and not to dismiss him?—It is usual and customary.

811. Have you ever known a case in Ireland, except in an abominable case of immorality, in which the Local Government Board dismissed a medical officer without first giving him the option of resigning?—No; I have never known a case in which a sealed order for dismissal has been issued except for what you describe.

812. As being grossly immoral?—Yes.

813. Then the Local Government Board of Ireland in dismissing Dr. Kenny under a sealed order, without giving him the option of resigning, have done an act which has never been done with reference to any other medical officer in Ireland, as far as you know?—As far as I know.

814. And it is that Board that you ask us to entrust these powers to?—No.

815. You say in this letter "The Council have no reason to doubt that the Local Government Board would properly and impartially do justice to all interests if endowed with sole powers concerning the superannuation allowances of union officers, but they positively assert that a control divided between the board of guardians and the Local Government Board could not possibly work satisfactorily, and afford justice to the claims of retiring officers, because officers who by reason of infirmity were constrained to resign, would not be capable of putting forward their claims to the best advantage, and an appeal would at best result in a compromise, and but seldom in an award of the maximum; for boards of guardians, judging by past experience, would usually vote but an insignificant amount, which the Local Government Board could neither approve, nor yet increase to the maximum. Under existing law the superannuation allowances of each union officer, who was fortunate enough to be awarded any, is payable out of the rates of the union in which he served, and under such circumstances it was reasonable that the board of guardians of the union should have had a voice in the disbursement of its rates, but Government admits that after 17 years' trial that system has been found not to work satisfactorily?"—Yes. Speaking generally, I desire it to be understood that we have confidence in the administration of the Local Government Board, we take great exception to individual cases, and especially the exception in the case of Dr. Kenny, but speaking generally, we have belief in their discretion and desire to do what is right, and we

are willing to accept the discretion of the Local Government Board.

816. Having had of three permanent officials one a friend in court?—The Medical Commissioner of the Local Government Board so far from being a friend in court of the Irish Medical Association, it is the fact, has had no communication whatsoever with us except the most distant official communications.

817. But he has his professional feeling?—I think so; and I am very glad to believe that it is strong in his mind.

818. Mr. Justin McCarthy. You are aware of the unpopularity of the medical officers?—Yes.

819. What in your opinion are the causes generally of their unpopularity?—A man may be brusque in his manner and zealous in the discharge of his duty, and thereby make himself unpleasant to the guardians; or he may perhaps not hold the same political or religious views which they hold strongly; all those things would cause unpopularity.

820. Would the religious views of the medical officer influence the board of guardians much?—Yes, there are many districts in Ireland where a person of one religious view would not have the slightest chance of being appointed to the office, no matter what his qualification as a medical man may be.

821. Being appointed, would it influence the board of guardians much in the question of his superannuation supposing that he had done his duty properly?—Yes, I think it does influence them largely in that question.

822. In Dr. Chapman's letter he refers to a number of men having Land League opinions upon boards of guardians; has that been increasing of late?—Yes, it has been considerably increasing.

823. In point of fact, a certain objection to these Land League opinions does influence the minds of the promoters of this Bill?—No.

824. I mean, the original promoters of it?—The Irish Medical Association have no political opinions whatever, and strenuously and studiously avoids having them, or expressing them in any way.

825. Then does this letter of Dr. Chapman's express the views of the Association that Land League opinions amongst guardians are on the increase, or is it put forward as an expression of the views of the medical profession?—I think that that phrase was a very unhappy mode of expressing the fact, that the medical officers being dependent upon boards of guardians would necessarily conform to a certain extent to the views of the board of guardians, and would necessarily hold those opinions.

826. Medical men, we know, are not generally strong politicians, but it is the fact that some medical officers have themselves been members of what was the Land League?—Yes, it is the fact.

827. If the Local Government Board had supreme control do not you think these men would be very unpopular with the Local Government Board?—I have never known the Local Government Board to be animated by political reasons in refusing or granting anything to medical men, except in the case of Dr. Kenny; but as to increasing a man's superannuation or decreasing it, or altering his salary, I have never known, nor have I any reason to believe, that political considerations have entered upon the question at all.

828. Do not you think that that very appeal of Dr. Chapman's upon the ground of the increase of these opinions shows that he thought these opinions would be unpopular with the Local Government Board?—It goes without saying that they are unpopular; but I do not think that he intended to convey that.

829. Still the term "unpopularity" has two applications; if it applies in one way with regard to the guardians it would apply the other way with regard to the Local Government Board; is not that so?—Yes, but this referred to the power of the Local Government Board as a

sanctioning power, and is therefore unimportant in comparison with the originating power of the board of guardians.

830. Supposing that they had a supreme power, what would you say?—We would be willing to trust ourselves to the Local Government Board.

831. Still this does appear that an element of unpopularity would exist upon the one side as well as upon the other, only in the board of guardians assuming you are correct, one set of opinions would be unpopular, and in the Local Government Board another set of opinions would be unpopular, but there would be the external influence in the one case and not in the other case; is not that so?—I do not admit that it would have any such effect upon the Local Government Board; I have no ground for the admission; I have watched the cases very strictly that have come before the Local Government Board, with a view of seeing that justice was done, and, speaking generally, I have never seen any bias arising from those causes.

832. We had one remarkable case against the Local Government Board, and no such remarkable case against boards of guardians?—I admit that case and deplore it, because I think it was wrong.

833. Mr. Daly. You told the Committee you were a member of the Medical Association?—Yes.

834. How long has the attention of the Medical Association been directed to this question approximately?—A few years after 1869, when the last Act was passed.

835. Then in effect we will say from 10 to 13 years?—Yes.

836. And you here represent the views of the Irish Medical Association upon this question?—Yes.

837. You stated that one of the reasons why you sought a change in the law is, that the present system results in injury to the public servants?—Yes.

838. And you adduce, as a reason why the Committee should adopt your view, some instances, and those instances are presumably a number of doctors who hold on, to the prejudice of the public service?—Yes.

839. You have enumerated 71 doctors whose age averaged over 66?—Yes.

840. And you arrive at that age of 66 on the basis of their being 21 years of age when they entered the service?—No, when they obtained their medical qualification, not entered the Poor-law service.

841. That is to say, you assume that they got their medical diploma when they were 21?—Yes.

842. You assume that they were 66 years of age on the basis that they were 21 when they got their medical diploma?—Yes; they might be more than 21, but they cannot be less.

843. As a matter, of fact, for a gentleman of your experience, do you consider the basis of 21 a reliable basis?—No.

844. What would be a reliable basis?—I should say 24.

845. Would one be wrong in saying that a fairly reliable basis would be from 28 to 30?—Not for obtaining their qualification. It would be correct to say that they did not enter the Poor-law service till they were from 28 to 30; but it would be incorrect to say that they did not obtain their qualification till they were from 28 to 30.

846. For a gentleman going through a course of study, and taking the exigencies of life, what would be a reliable age to take at which he would get his medical diploma?—Twenty-four.

847. Or 25?—Not as late as 25; young men commence their studies generally at 18, and that gives them three, four, or five years to qualify.

848. Assuming it to be 25 it would reduce the average age of the 71 gentlemen to 62 years of age?—It would take three years or something like that off.

849. It would bring the average age of these gentlemen to 62 years of age?—No, it would increase their age, not decrease it; because if instead of taking their qualification at 21 they took it at 24, they would be four years older men in the service.

850. What other means have you of arriving at the basis, except the length of time they were in medical situations, or by their particular diplomas?—Young men are not allowed to enter the Poor-law medical service under 23 years of age, and those who were 23 years of age in the year 1839 would now be over the statutory retirement age.

851. What I want to arrive at is this: you stated that there are 71 doctors whose average age is 66 years?—Yes.

852. Will you tell the Committee plainly how you arrive at that; what process did you take to arrive at it?—Any man who was 23 years of age in the year 1839 would be over 66 now.

853. But as a matter of fact, were all the 71 men officers of that age, by the date of their diploma; were they of such respective ages as that their average would be 66 years?—Yes. I have taken men who have got their qualification in 1839; they must have been 23 years of age or thereabouts at that time; therefore they would now necessarily be 66; if you take 39 from 82 it would make up the time.

854. Did you personally investigate each one of the 71 cases?—Yes; I did personally investigate them; I took the cases of the Poor-law medical officers, and I followed them in the Medical Directory, and found out at what time they qualified, and every man who had his qualification in 1839 I took to be of the statutory retirement age according to that calculation.

855. You make out of the total practitioners in harness there were 71 persons who have not retired, and whom you assume would retire if they were satisfied that they would get superannuation?—Yes; who have arrived at the statutory age.

856. That is in effect of the number of men 7 per cent.?—Yes.

857. From your experience in Dublin, in London, in Paris, in Vienna, and in all the great centres where medical skill is exercised, and where there are the leading physicians, and the men entrusted with the most important medical duties, would 7 per cent. of them be an unreasonable percentage of those actually in the very best practice, the men to whom the public look with most confidence, and whom they consult on account of their medical skill, would 7 per cent. be an unreasonable percentage of those gentlemen who occupy the position of the first physicians and medical men in the world?—No, I think not.

861. I want to refer you to instances where superannuation was not granted, which might be remedied, under this Bill; you adduced 10 cases?—Yes.

862. In preparing the evidence for this Committee, with an association so powerful as your own, and with such a period of investigation as 10 different years, you have made presumably the best case that can be made for your side?—We have had the grievances arising from the Act for from 10 to 13 years, as you say, but no agitation or move towards obtaining the Bill now before the Committee was made till about three years ago.

863. But you have had your attention called to this state of facts for a period of from 10 to 13 years, and the persons aggrieved had full cognisance that you were collecting details, and did in effect supply you with the results of the most remarkable cases?—The data were collected within nine months.

866. You adduced instances of 12 medical gentlemen who retired at 44 years of age, with an average length of service of 12 years?—Yes.

867.—And with a view of showing the inconsistencies under the present system, you contrasted that state of facts with 12 gentlemen who, having attained the age of 62 years, and having an average length of service of 32 years, were refused superannuation?—Yes.

868. Are you aware within your own knowledge or from special information received, whether there were any special circumstances connected with the 12 gentlemen who retired at 44 years of age, with an average length of

service of 12 years?—I know the names of them all; but I do not know that there were any special circumstances.

869. But you are not prepared to tell the Committee that there were not special circumstances?—No; nor do I in the least infer that these gentlemen having retired at this age were undeservedly retired, because their condition of health may have been such as to render them deserving of retirement; but I merely wish to point out that the law acted unequally in this way.

872. You stated as regards a reason for the change in the law, that a doctor may not be personally popular with the board of guardians from whom he seeks superannuation?—Yes.

873. And you said you thought that that might arise from conscientious performance of his duties?—Yes.

874. And you thought that in the conscientious performance of his duties, due supervision and ordering of sanitary works might be one of the reasons?—Yes.

875. From your experience, do not you think that, as regards the unpopularity occasioned by undue zeal in promoting sanitary works, the unpopularity with the board would be generally with the *ex officio* members, and the unpopularity would be, because they are generally representatives of property upon the board?—I should not say that they were the representatives of such property as would come within the cognisance of the sanitary officer, because the offences are usually the keeping of pigs in improper places, and nuisance from manure heaps, and such things of which the *ex officio* guardians no doubt have their share, but it does not necessarily fall upon the higher classes of property.

878. Then in effect, of course, no assertion that you make before this Committee is of very great value, but I am sure you will not think that I am speaking disrespectfully when I say, that in the absence of the knowledge, as far as that knowledge is absent, it vitiates that part of your evidence?—But I have stated in my evidence upon that, that the medical officers in the discharge of their sanitary duties were liable to make enemies of the board of guardians, and that the more assiduous and zealous they were in the discharge of that duty, the more enemies they make; and that their loss of unpopularity under these circumstances militated against them, and was liable to militate against them in their getting superannuation, but as to whether the enemies are of one class or another, I can express no opinion, because I have no personal knowledge of how the property is distributed in the various dispensary districts in the way you speak of.

883. Now we come to the abuse of the red tickets, which was elicited from you by the right honourable Member for Dublin University: you stated that there was an abuse of the red tickets, and that the abuse was more by the guardians and dispensary members than by the relieving officers?—Yes.

884. And you stated further instances within your own knowledge of shopkeepers who granted red tickets to their customers?—Yes, dispensary tickets; there are two kinds; they might be red or they might be black.

885. The red is urgent?—The red is for the doctor to visit the patient, and the black is for the patient to come to the doctor.

886. Whether black or red, you stated that, within your own experience, it was perhaps not the general practice, but the practice of shopkeepers to grant those to their customers?—Yes.

887. What remedy does the Poor Law provide for an abuse of that kind?—In the first place it is my contention that, upon the strict matter of law, the medical officer need not attend unless the whole body of the ticket, including the name of the person, is filled in in the handwriting of the grantor, that is, the person entitled to grant the ticket; therefore the system at present existing of filling up tickets *en bloc*, and allowing subordinate persons, like an assistant in the shop or the daughter of the house to issue the tickets

is illegal. That is number one means of checking the thing which no medical officer avails himself of, because the danger of refusing to attend such a case for such a reason might be so serious that he might get himself into trouble. As to the other remedies for the system, the only remedy that he has is to apply to his dispensary committee to cancel that ticket. The dispensary committee meet not perhaps for three months, and therefore the case would have been cured or got rid of, possibly dead, long before the three months came round, and there is no use in the doctor availing himself of his legal privilege in proceeding to cancel the ticket; so that, as a matter of fact, there is no remedy in these cases; the medical man attends the case himself, and he has no escape from it.

888. Has it occurred to a gentleman of your experience that there is this very easy remedy; what would there be to hinder the doctor finding out an abuse and speaking to either an *ex officio* guardian, or an independent elected guardian who did not practise this system, or calling attention by a special resolution of either the dispensary committee or the board of guardians to the fact, and making a rule that unless the ticket was properly formulated, the dispensary physician need not attend?—Such a rule already exists, but it is not acted upon because the medical officer dare not avail himself of the law to refuse to attend the case.

889. Is it a rule of the Poor Law, or a special resolution of individual boards?—The Local Government Board has made that order, and it is printed upon the back of the ticket that the ticket must be filled up in the handwriting of the grantor; therefore filling up the signature only, and leaving another person to fill in the name of the person, is an illegality; nevertheless the medical man dare not decline to attend upon those grounds, it would be attended with too much danger. He might escape dismissal on the ground of its being illegal, but he would not escape censure for having refused to attend.

890. You instance as another of the arguments why there should be a change in this law, that from 1869 to 1880 (quoting from the paper which you handed in), there had been 189 applications?—Yes.

891. And of those 12 had been refused?—Yes.

892. And you said also that not only had the 12 been refused, but that the 177 had been granted?—Yes.

893. I am sure you are too good a mental calculator not to recognise that 12 officials out of 189 is under 8 per cent.?—Yes.

894. Then one of the reasons why you advocate the change of this law is that under 8 per cent. of the applications for superannuation had been refused?—Yes.

895. And you do not know of your own knowledge or from information that you have ever received of the special circumstances attendant upon those twelve cases which represent under 8 per cent.?—The special circumstances are set forth in Mr. Meldon's return.

896. Then I assume that of those 12 cases, the six cases which you gave us to-day of the gentlemen who had attained the ages respectively of from 60 to 76, and services respectively of from 26 to 42 years, on account of your giving prominence to those, they form a portion of the 12 cases?—Yes.

897. That is to say, that these 12 cases referred to absorb the six particular cases which you gave?—Yes.

(To be continued.)

THE memorial to the late Prof. Balfour has taken a double form; there will be created a Studentship of the value of £200 per annum, the holder of which is to devote his whole time to original research in biology, more especially in animal morphology, and also a fund out of which occasional money grants will be awarded to further research in the same science. This is better than a statue.

IRISH POOR-LAW INTELLIGENCE.

DISMISSAL OF UNION OFFICERS BY BOARDS OF GUARDIANS.

The following additional correspondence, which closes the subject for the present, has taken place between the Council of the Irish Medical Association and the Irish Local Government Board :—

LISMORE UNION.

(Copy).

Local Government Board,
Dublin, 7th November, 1882.

SIR,—The Local Government Board for Ireland have had under consideration your letter of the 26th ult. respecting the recent resignation by Dr. O'Reilly of his appointment as medical officer of the workhouse of Lismore Union, and the Board desire for the information of the Irish Medical Association that the vacancy created by Dr. O'Reilly's resignation has been filled up by the guardians, and the Board do not consider it necessary to enter into a correspondence on the subject. With reference to the request of the Council that the Local Government Board will take steps for the reinstating of Dr. O'Reilly in the office which he held, the Board desire to point out that when a medical officer's appointment becomes vacant by resignation or otherwise, it can only be filled by an election conducted in the manner prescribed by the general regulations.

By order of the Board,

(Signed) W. D. WODSWORTH.
Assistant Secretary.

To Wm. Thomson, Esq., M.D., &c.

Irish Medical Association,
December 8, 1882.

SIR,—I am directed by the Council of the Irish Medical Association to state, in reply to your letter of 7th Nov., "No. 32,679 Lismore Union," that, in view of the circumstances that the office vacated by Dr. O'Reilly has already been filled by the appointment of another medical practitioner, the Council will not continue to urge the reinstatement of that gentleman.

The Council desire to remind the Local Government Board that Dr. O'Reilly's resignation of office was not a voluntary act, but that he was forced, notwithstanding his repeated protests and appeals for full investigation of the circumstances, to vacate his appointment in consequence of the unjust, and—as the Council believes—illegal course adopted by the Board of Guardians, not only with the concurrence, but apparently at the suggestion of the Local Government Board for Ireland. The Council hold the opinion that suspension of an officer

from the performance of his duty is a power entrusted to Boards of Guardians solely, in order that they may be enabled, in case of emergency, to dispense temporarily with the services of an officer pending the immediate investigation of some serious charge, which would, if proved, render him unfit to continue in office, and with a view to his reinstatement if the accusation were not established. To use such a power for the purpose of permanently removing an officer against whom no such charge has been made or sustained is, in the opinion of the Council, an abuse of the law, inasmuch as it is an assumption by the Board of Guardians of the power of dismissal, which is the prerogative only of the Local Government Board, and is exercised by them subject to the approval of Parliament.

The Council of the Irish Medical Association apprehend that by the course which has been pursued towards Dr. O'Reilly, a precedent may be established which it would be their duty to contest, as they believe that course to be altogether illegal and contrary to the intention of Parliament, and as the establishment of such a precedent would obviously be most prejudicial to the status of Poor-law medical officers.

In this instance, Dr. O'Reilly's resignation appears to preclude the Council from bringing the case into court and obtaining a judicial decision on the subject; nevertheless, the Council desire to state emphatically their opinion that, so long as the State compulsorily imposes upon Poor-law medical officers duties, the proper discharge of which tends to bring them into variance, if not conflict, with Poor-law guardians it is essential to the efficiency of the service that the position of those officers shall be rendered as independent as possible, and that they shall receive at the hands of the Local Government Board the utmost consideration and protection in the due performance of their duties. Were it not that Boards of Guardians are aware of the powers conferred by the Legislature on the Local Government Board to protect their officers against harsh and unjust treatment, a considerable number of those officers would doubtless find it impossible to discharge their duties efficiently and conscientiously. The Council therefore expect that the Local Government Board will afford to Poor-law officers the protection necessary for the performance of their functions, and not afford its countenance to unscrupulous attacks, nor visit with punishment any complaints until it has, by a thorough and independent investigation, fully satisfied itself that the case is one which really merits the punishment meted out. In the case in question the Council regret to think that no adequate investigation was held by the Local Government Board. The Council therefore feel, that they have no other course open to them than to reiterate emphatically their protest against the compulsory removal of Dr. O'Reilly from office at the caprice of the Board of Guardians, and, without any

charge whatever having been proved which affects his fitness for his medical functions.

I am, &c.,

WILLIAM THOMSON,
Hon. Sec. to Council.

To B. Buks, Esq.

Local Government Board,
Dublin, 11th Dec., 1882.

SIR,—The Local Government Board of Ireland acknowledge the receipt of your further letter of the 8th inst. relating to the resignation by Dr. O'Reilly of his appointment as Medical Officer of the workhouse of Lismore Union.

By order of the Board.

(Signed) W. D. WODSWORTH, Assist. Sec.

LURGAN PETTY SESSIONS.

AN IMPORTANT REGISTRATION CASE.

THE Registrar-General for Ireland summoned John M. J. Scott, M.D., an extensive medical practitioner in Lurgan, and also a woman named Sarah M'Cann, for having wilfully and knowingly made a false declaration about the death of Charlotte M'Cann, daughter of one of the defendants.

Mr. Hazlett, S.C.S., appeared for the prosecution, and Mr. Mahaffy for the defence in both cases.

Mr. Hazlett said that this prosecution was brought against Sarah M'Cann and Dr. Scott under the 30th sec. 43 and 44 Vict., chap. 13, which provides that any person who wilfully makes any false certificate under or for the purposes of this Act (Births and Deaths Registration (Ireland) Act, 1880), or forges or falsifies any such certificate or declaration, or any order under this Act, or knowing any such certificate, declaration, or order to be false or forged, uses the same as true, or sends the same as true to any person, shall be liable to a penalty not exceeding £10.

Dr. Agnew, medical officer of Lurgan dispensary, deposed that he attended Charlotte M'Cann on the 24th May, 1881. He did not see her until October of the same year. He saw her again in the beginning of December, 1881, when he made a detailed examination and found that the girl was suffering from consumption. He saw the patient again in June, 1882. She was then in a hopeless condition. He saw her again on the 29th September. About five days before her death, on the 6th October, the mother of the deceased came to the dispensary with a certificate signed by Dr. Scott. This certificate was to the effect that Dr. Scott saw Charlotte M'Cann last on the 27th September, 1882, that she died on the 5th October, 1882, and that to the best of his knowledge and belief the cause of her death and the duration of her illness were as follows:—Debility, two months; bronchitis, one month, seven days. Dr. Agnew drew the woman's attention to the fact that the declaration both as to the disease and the duration of the illness was untrue. Witness himself, on the direction of the Registrar-General, had drawn out a certificate declaring the cause of death to be phthisis, from which she had been suffering for nine months.

On cross-examination, witness deposed that the girl was suffering from an attack of hæmorrhage some time before her death. He believed continued attacks of bronchitis would affect the lungs. He did not say to the woman that Dr. Scott would hang himself for money.

Dr. Scott was examined for the defence, and deposed that before December, 1881, he was called in to attend this patient and prescribed for her. She was then suffering from bronchitis, and there were no symptoms of consumption. The deceased went back afterwards to her work, having got better of the disease. She afterwards left her work, not being able to sit at the machine, owing

to her being afflicted with piles. He saw her again in September, 1882. She had again been attacked with bronchitis. He examined her again with the stethoscope and found that her lungs were choked up with phlegm. He saw her again twice. He examined her repeatedly, and found that she was suffering from bronchitis. Besides, he examined her with the thermometer, as is usual in cases where there is any doubt, and found that there was not the slightest trace of consumption. The girl died of bronchitis and debility. He asked the woman how long her daughter had been ill, and she said one month. He had every reason to believe that the woman's statement was true.

Mr. Mahaffy said he had other witnesses to examine for the defence, but the Bench thought it unnecessary to hear them, and granted a dismissal on the merits.

IMPORTANT TO DISPENSARY DOCTORS.

THE hon. sec. of the Athlone Dispensary Committee has received the following copy of a letter from the Local Government Board:—

"SIR,—I am directed by the Local Government Board for Ireland to acknowledge the receipt of your letter, and of its enclosures relative to the refusal of Dr. White to act as temporary substitute for Dr. Langstaff, the medical officer of the Athlone Dispensary District, and requesting to be informed how you are to act under the circumstances, and whether the committee of management can appoint a substitute at Dr. Langstaff's expense, and in reply I am to inform you that the Board of Guardians would not be authorized in making any deduction from Dr. Langstaff's salary so long as he continues in office. The committee of management should, however, make provision for attendance on the sick-poor pending Dr. Langstaff's resignation, or his return to discharge his duties, and the Local Government Board presume that under these circumstances the guardians will, if necessary, agree to pay a temporary substitute for Dr. Langstaff, who has been on leave for an unusually long period.

"By order of the Board,

"W. D. WODSWORTH, Assist. Sec.

"To John M'Donnell, Esq., Hon. Sec.,
Athlone Dispensary Committee."

KELLS.

CHARGE AGAINST A DOCTOR.

At the Petty Sessions, Jan. 15th, the presiding magistrates were:—George MacCarthy, R.M.; Messrs. John Tisdall, George Bomford, Thomas Rothwell, and John Keating. The magistrates sat in their private room to investigate a charge of indecent assault made against Dr. Thomas F. Sparrow, medical officer of Kells, by a dispensary patient named Kate Murphy. Mr. George Fottrell watched the case on behalf of the private prosecution. Mr. Richard Adams (instructed by Mr. T. Lynch) defended. Dr. Sparrow was accompanied to court by several medical men of the district, including Dr. Nicholls, of Navan, Drs. Ringwood, Dundas, and Canton. The girl was examined and cross-examined at considerable length by Mr. Adams, who was about to open the case for the defence, when the bench, after a brief consultation, announced through Mr. MacCarthy, R.M., that they had heard enough of the case, that they were unanimous in dismissing it on the evidence of the prosecutrix herself, and that Dr. Sparrow was, in their opinion, free from any imputation. Mr. Adams said that had the case proceeded Dr. Sparrow had in court many witnesses—medical and others—who could have established, beyond a doubt, that so far from being guilty of the extraordinary charge made by the girl against him, he had simply done his plain

IRISH POOR-LAW INTELLIGENCE.

IRISH COUNTY INFIRMARIES' GRANTS.

WE print to-day a very important discussion and judicial decision with reference to the grant for the County Kildare Infirmary, from which it appears to be the law—

a. That the Grand Jury have no power to present a sum for the maintenance of a county infirmary unless at the Presentment Sessions the cesspayers have previously assented to a grant of greater or less amount.

b. That notwithstanding the withdrawal of the grant for the infirmary, the Grand Jury may vote payment of the salary of the surgeon.

It is unnecessary to speculate upon the reasons which led to the distinction between the two presentments. Possibly, as Chief Justice Morris said, it was considered advisable to reduce to a minimum the chances of the rejection of the presentment for the surgeon's salary, because the surgeon is in certain cases compelled to discharge gratuitously duties which do not appertain to the infirmary of which he is the medical officer, or possibly it was considered just to protect the surgeon from the injustice of being deprived of payment for services rendered. If the Legislature apprehended that the sessions might, if their approval were made a condition of the presentment, some day or other decline to remunerate the surgeon for work he had already done, their suspicions regarding popular notions of fair play were not without justification; for had not the Kildare Grand Jury been competent to make presentment for Dr. Chaplin's salary without the assent of the sessions, the surgeon of the Kildare Infirmary would have been deprived of remuneration for services extending over some months.

We have already expressed on many occasions, and we now reiterate our great regret to observe the existence and growth of hostility to the county infirmaries on the part of those who call themselves "the popular party." We do not in the least dispute their moral or legal right to refuse to expend the county cess on these institutions, but we believe that if they calmly considered the subject they would not adopt any such course. In the first place we think that any one who looks at the matter from a non-political standpoint, and in the public interest, will agree with us that the abolition of the Irish County Infirmary would be a grievous loss to a numerous section of the popular party, and would involve the withdrawal of a considerable amount

of money contributed by private charity for sick relief, and would therefore entail an increase in the expense of providing that sick relief at the public cost. We most earnestly deprecate any invidious comparison between the workhouse hospital and the county infirmary to the disfavour of either. Each has its scope and use. The union hospital is indispensable for the care of the infirm and destitute, and for the reception of those patients who are not unwilling to enter the union.

The county infirmary, on the other hand, has its very important function in ministering to the wants of the more acute and temporary cases of disease amongst the small farming class, who, while incapable of paying for medical attendance in idleness and at home, are not to be blamed if they object to pauperise themselves and their families by entering the union. In England these cases would be provided for by a sick club or in a provident hospital, but in Ireland no such institutions exist, and surely it would not be wise to put such patients to the alternative of remaining at home uncared for, or entering the union in association with the destitute.

But if the action of the enemies of the county infirmary were to succeed, the financial result to the taxpayer would be all the worse, for the majority of the patients who are now maintained by means of private subscriptions in the infirmary must needs become chargeable on the union funds, and a loss instead of a gain would accrue to the taxpayer.

We hope to see the question of maintenance of Irish County Infirmaries influenced by other considerations than those of politics, and that they will be dealt with by the cesspayer on their merits as public institutions. No one has so great an interest in sustaining them as the poorer cesspayers, and we hope they are not so unmindful of the interests of their class as to destroy the institutions which have for nearly a century done them such good service.

THE POOR-LAW SUPERANNUATION BILL.

THE Irish Poor-law Superannuation Bill will be reintroduced by Mr. Herbert Gladstone to-morrow, amended as recommended by the Select Committee of last year. It will probably not be in print for some days afterwards, but we shall inform our readers respecting it, if possible, next week.

THE TENURE OF OFFICE OF IRISH POOR-LAW MEDICAL OFFICERS.

THE following important communication, to which we hope to refer at greater length in our next issue, has been made by the Council of the Irish Medical Association to the Irish Local Government Board :—

Irish Medical Association,
Royal College of Surgeons,
8th March, 1883.

To the Secretary,
Local Government Board for Ireland.

SIR,—The attention of the Council of the Irish Medical Association has been directed to the terms of Articles 36, 39, and 40, of the order of the Local Government Board ("General Regulations for the Administration of Work-houses"), dated December 18th, 1882, which has been recently issued by your Board, in substitution for Articles 38, 41, and 42 of the order of January 19th, 1852.

The Council observe that additions have been made to the original regulations, such as to authorise boards of guardians throughout Ireland, not only "at their discretion," to suspend union officers from the performance of their duties, and to deprive them of their salaries during the period of such suspension, but also to dismiss them from office, if the Local Government Board does not see fit to remove such suspension; while the order does not appear to contain any provision requiring boards of guardians to state their reasons for thus exercising their "discretion," or to institute any inquiry into the truth of charges which may have been made against the officer.

The Council, having already—in a recent correspondence with the Local Government Board respecting the removal of Dr. O'Reilly from his appointment as medical officer of the Lismore Workhouse—expressed their opinion as to the great injustice and inexpediency of submitting the tenure of office of the workhouse surgeon to the "discretion" of the guardians, subject only to a *nominal* control by the Local Government Board, refrain now from repeating the arguments and opinion then expressed. The Council, however, feel it necessary to state their unqualified belief that the dependence of the medical officer's tenure of office upon the caprice of the board of guardians must render impossible the conscientious and efficient discharge of that officer's duties, and certainly cause the permanency of his appointment to be largely influenced by personal or political considerations altogether apart from his competency or efficiency for his duties.

The Council, being of opinion that it never was the intention of Parliament that union officers should be dependent to this extent upon the goodwill of the majority of the board of guardians, have carefully examined into the law (1 and 2 Vic., cap. 56, sections 31 and 33) governing the appointment and dismissal of union officers, and are satisfied that the authority to remove a union medical officer, and the responsibility arising out of such an act, rest upon the Local Government Board alone, and that a dismissal or suspension by any other body whatsoever is wholly illegal and inoperative. The Council consider that any rule made for the purpose of transferring that responsibility to others altogether *ultra vires*. In this

view the Council are sustained by the opinion of Mr. Purcell, Q.C., on the points raised, and I am directed to forward herewith, for the perusal of your board, a copy of the case submitted to counsel, and his opinion thereon. I am further instructed to request that the Local Government Board, having taken such steps as they may consider expedient to confirm Mr. Purcell's opinion, may see fit to cancel their order referred to, and issue an amended one, which shall be in strict compliance with the provisions of the law on this subject, in order to give effect to the obvious intention of Parliament.

I am, Sir,

Your obedient servant,
W. THOMSON, F.R.C.S.I.,
Hon. Sec. to the Council.

[COPY.]

Re Irish Medical Association,

Opinion of THEOBALD PURCELL, Q.C.

1. Counsel will therefore please advise whether the Local Government Board can legally, by sealed order or otherwise, empower a board of guardians to dismiss or suspend the medical officer of the union under any circumstances whatever.

I am of opinion that the Local Government Board have no power to delegate to boards of guardians any authority to dismiss or suspend the medical officer of the union, and that the general orders to this effect in the Articles 39 and 40 of their recent Circular are *ultra vires* and illegal.

2. Should Counsel be of opinion that the Local Government Board (though not being able to delegate their power of dismissal) can legally delegate the power of suspending a union medical officer, can a board of guardians exercise such power of suspension in such a way as to practically dismiss the union medical officer? And Counsel's general opinion is requested.

I find no provision in any of the Acts in relation to the power of *suspension*. In my opinion, neither the Local Government Board nor a board of guardians have power to suspend a union medical officer, or to deprive him of his salary, except from the date of his dismissal by the Local Government Board, and that the provision in Article 36 of the recent Circular as to the deprivation of the medical officer's salary from the date of suspension is also *ultra vires*.

T. A. PURCELL.

71 Harcourt Street, Dublin,
15th February, 1883.

No. 8,835—1883—Miscellaneous.

Local Government Board, Dublin,
March 10th, 1883.

SIR,—I am directed by the Local Government Board for Ireland to acknowledge the receipt of your letter of the 8th inst., with enclosure; and I am to acquaint you that your communication will receive consideration.

I am, Sir, your obedient servant,
W. D. WODSWORTH, Secretary.

W. Thomson, Esq., M.D.,
Stephen's Green.

**UNION OFFICERS' SUPERANNUATION BILL
(IRELAND).**

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The time is rapidly approaching when it may be expected that the Union Officers' Superannuation Bill will be introduced into Parliament. I do not think that the Bill has ever been fairly examined from the side of the public and the guardians, so I propose to scrutinise it from that aspect.

1. At present a pension is looked on by many guardians as, to some extent, eleemosynary—they consider whether the applicant has private means—and unless he is destitute will give him nothing. It is manifest that a pension given under such circumstances counts for nothing in estimating the value of the appointment. The Public Services—Civil and Military—command the services of efficient men, at lower salaries than they can be obtained by private individuals, because the retiring allowances are certain. The Poor-law service loses the benefit of this as long as pensions are contingent. Make them certain, even though lower, and salaries need not be advanced for some time longer.

2. The Bill will leave the initiative in giving pensions to the boards of guardians, but will fix the scale on which they are to be given. Had the guardians been left out of consideration, as was once proposed, it might have been possible for an officer over sixty years of age, who had been guilty of misconduct deserving of dismissal, to anticipate the result of an investigation by applying to the Local Government Board for superannuation, and getting it before his misconduct had been brought fully to light. Now the guardians will be fully cognisant of every application for superannuation, while they will be saved the invidious duty of fixing the amount in each case. There can be no question that in many cases it is contrary to their individual sense of what is just, and in deference to a portion of their constituents that guardians have supported the reduction of pensions to a minimum or vanishing quantity.

3. The payment of pensions out of a rate levied over all Ireland will be a great relief to unions in which there happen to be several aged officers, while the distributed charge will be so light as to be hardly appreciable.

4. Finally, there is no danger of the passing of the Bill resulting in a *stampede* of union officers. Men will hold on to the position to which they have been accustomed as long as they possibly can, and it is a law of Nature that whenever an elderly man retires from active life he very soon dies. There is no danger of a high average duration of pensions.

Taking all these things into consideration, I think there are fair grounds for regarding the Bill in question as one which ought to be supported on public grounds.

I am, &c., CIVIS.

COUNTY KILDARE GRAND JURY.

THE COUNTY KILDARE INFIRMARY—IMPORTANT QUESTION.

THE following resolution passed at the County-at-Large Presentment Sessions was read:—

“Resolved—That in consequence of three other Infirmaries being in the different unions of the County Kildare—namely, Naas, Athy, and Celbridge—we, the cess-payers of this county, consider that the Infirmary in Kildare is not required, as we believe, from reliable authority, there is ample accommodation for all patients in the other three.”

Application No. 16, in the County-at-Large, was as follows:—“To the Treasurer of the Kildare Infirmary, for maintenance of same, £500, disallowed by Road Sessions.” Application No. 17 was for £47 for the salary of the surgeon to the infirmary, and was also disallowed by Road Sessions.

The Foreman—On more than one occasion we have passed presentments which have been thrown out at Presentment Sessions.

Mr. Maunsell said a similar case to this was before Judge Lawson in a northern county—Antrim he thought—and the judge fiat the presentment.

Mr. Galloway, solicitor to the Grand Jury, said the presentment should go before the judge if it were passed.

Mr. Brown appeared on behalf of the cess-payers to support the decision at which the County-at-Large Road Sessions had arrived. There was, of course, no legal question at all involved here. It was a question whether the Grand Jury would continue this institution.

Mr. Galloway referred the Grand Jury to the case of the Kerry Fever Hospital, in which it was decided that the Grand Jury were bound to make a presentment for the maintenance of the institution in question. He read the following report from the *Irish Law Times*:—

“Re Kerry Fever Hospital Presentment. (Before May, C. J.; Pales, C. B.; O'Brien and Lawson, J.) November 30, 1878.—Grand Jury; Fever Hospital; Nominal Presentment. 6 and 7 Wm. IV., c. 116, sec. 83. ‘Shall or may present.’ Construction—As long as a fever hospital, established under the hospital statutes, legally subsists, the Grand Jury are bound to present for its maintenance, and in substantial amount, notwithstanding that they may be of opinion that the further maintenance of the hospital is unnecessary. Case reserved for the Lord Chief Justice as follows:—‘At the last Summer Assizes for the County of Kerry I was requested by the Grand Jury of that county to advise them in the following matter:—It appeared for the last twenty years and upwards a fever hospital for the county had been maintained by Grand Jury presentments, made at each Assizes, pursuant to the provisions of the 83rd section of the Act 6 and 7 Wm. IV., c. 116. The hospital, it appeared to be admitted, had been always conducted in a satisfactory manner. Many of the Grand Jury were in favour of making either no presentment for the hospital, or merely a nominal presentment, being of opinion that its further maintenance was unnecessary, having regard to the provisions made by the Acts for the relief of the poor in cases of sickness. Counsel for the hospital contended before me that the Grand Jury were bound to present a substantial sum for the maintenance of the hospital. I informed the Grand Jury that I would consult the judges on the point, and communicate their opinion. I should therefore wish for the opinion of the judges upon the question whether, under the above circumstances, the Grand Jury were bound to present a substantial sum for the maintenance of the said hospital. The Chief Justice delivered the opinion of the judges as follows:—‘We are all of opinion that the matter is not left to the discretion of the Grand Jury, but that they are bound to present a substantial sum for the maintenance of the hospital, and cannot make either no further presentment or a merely nominal presentment. From an early period the Legislature declared that the existence of fever hospitals in counties was necessary, and it follows that they should be maintained.’”

Mr. Cogan—In that case did the presentment go before the presentment sessions?

Mr. Galloway—It did, and was approved by presentment sessions.

Mr. Cogan said the question here was whether the Grand Jury could pass a presentment which had been refused by the sessions.

The Foreman then put the question whether the matter should be postponed until the Grand Jury should have obtained the opinion of the judge, or be now gone into.—Agreed to.

Mr. Brown—I am not putting it as a question of dry law. I wish to put the question whether the Grand Jury will continue an institution which a majority at the County-at-Large Presentment Sessions have decided

is unnecessary. I do not want the case to go off on a point of law.

The Foreman—No more do the Grand Jury. If this presentment be passed I think I may almost state for the governors of the Infirmary that they would not carry on the institution if the cess-payers throw out the presentment on a future occasion.

KILDARE SPRING ASSIZES.

(At the Crown Court, before Chief Justice Morris.)

THE COUNTY KILDARE INFIRMARY.

Mr. Bewley said that in this case he appeared on behalf of the Governors of the Kildare Infirmary to ask his lordship to direct the Grand Jury that they had power to present a sum for the support of the County Kildare Infirmary, and also a sum for the salary of the surgeon, notwithstanding that these presentments had not been approved of at Presentment Sessions. The Co. Kildare Infirmary was established under the 5th Geo. 3, chap. 20 (Ireland). That provides amongst others for the erection of an infirmary in Co. Kildare, and it provided by the 6th section that the grand jury should be at liberty to present a sum which was then only £100. That was altered by the 5th George III., c. 39, which raised the sum to £200, and provided that it should not be less than £150, and there was a proviso in that Act which had been re-enacted, that before any presentment was made an affidavit should be made by the surgeon, setting forth the number of patients, and also setting forth, in the form of a debtor and creditor account, the expenditure of the infirmary. By the 45th George 3rd, chap. 11, the sum was increased to £500. Then by the present Grand Jury Act—the 6 and 7 Wm. IV., c. 116, s. 85, it was provided that it shall be lawful for the Grand Jury to present a sum not exceeding £700 to be paid to the treasurer of such Infirmary for its support and maintenance, provided always that such application has been approved by the presentment sessions. At the last presentment sessions the usual application was made for the infirmary, and also for the salary of the surgeon. The infirmary was a most useful institution, and without apparently any reason the presentments were thrown out by the sessions. He submitted that notwithstanding the course pursued by the sessions, it was now competent for the Grand Jury to entertain the presentments. The 86th section deals with the salary of the surgeon of the infirmary in the same way, and that section does not contain any proviso that the application shall be approved by the sessions. Therefore, he submitted that this approval was merely a formal approval, and that if the previous section had been in other respects complied with, it was competent for the Grand Jury to make the presentment. The only case he could find of a similar kind was under the 83rd section, in reference to fever hospitals, the provisions of which were almost the same as those of the 85th section. In the Enniskerry case the nominal sum of 1s. had been passed at the presentment sessions, and the case came before Chief Baron Pigott, who advised the Grand Jury, notwithstanding, to present for a substantial sum, and they presented for a large sum accordingly. In the Kerry fever hospital case it was held that as long as the fever hospital legally subsists the Grand Jury is bound to present a substantial amount, notwithstanding that they may be of opinion that the institution is unnecessary.

His Lordship—I think there was a Mayo case.

Mr. Bewley—The effect of that was that it was competent for the Grand Jury to increase or diminish the amount granted by the sessions. That case was distinguished from this one by this: that a sum was passed by presentment sessions.

Mr. Molloy, Q.C., who appeared for the opposing cess-payers, said that the statutes previous to the Grand Jury Act, referred to by Mr. Bewley, should be considered as

out of the question, as they were repealed. Then they came to the 85th section of the Grand Jury Act, which enacts that it shall be lawful for the Grand Jury to present for the support of the infirmary, subject to certain conditions, one of which is that the application for the presentment shall be approved of by the Sessions. That proviso had not been fulfilled. In this county, as well as in other counties in Ireland, the question had been for a long time debated as to whether, having regard to the provisions made under the Poor Law and Medical Charities Act, county infirmaries were necessary institutions. In the Kerry and Mayo cases, referred to by Mr. Bewley, it was the Grand Jury objected to the presentment, but it had been passed by the Sessions. In a note in page 64 of Foot it appeared that in the case of the Enniskerry fever hospital it was held by Baron Greene that the Grand Jury could not present for the maintenance of the fever hospital, the presentment having been rejected by the Sessions. Then, at the following Sessions 1s. was presented, and that gave the Grand Jury power to present. Mr. Bewley had stated that there was no proviso regarding the approval of the Sessions in the 86th sec. dealing with the surgeon's salary. His Lordship would see that the surgeon stood in a peculiar position. If the infirmary were within five miles of the county gaol he was obliged to give his services to the gaol gratuitously, and under these circumstances the surgeon's salary is taken out of the consideration of the Presentment Sessions. But under the section that they presented the bonus to the infirmary, the presentment was subject to the approval of the sessions. He therefore submitted, having regard to the clear provisions of the 85th section, that the Grand Jury had no power to entertain the presentment for the maintenance of the infirmary.

Mr. Bewley—Mr. Molloy, I understand, admits that the rejection, so far as the salary of the surgeon is concerned, is wrong, and that therefore the Grand Jury are at liberty to make the presentment.

His Lordship, addressing the Grand Jury, said—In my opinion the presentment to the Treasurer of the Kildare Infirmary for the sum of £500 having been disallowed at the Presentment Sessions it is not competent for you to enter upon it. The words of the section appear very plain: "That such application shall have been approved of by such sessions." It is admitted that this was not approved of, but disallowed by the sessions; and it would appear to me you have no power over it, and I have no power over it—neither you nor I have any power except such as is conferred by the Act of Parliament. With regard to the salary of the surgeon that is a matter you can deal with, because the section which empowers the presentment is not subject to that qualification. Nay, more, while the application and certificate are brought forward at the Session, it is left out of that section that there shall be any approval of it. I can quite understand that, because if the surgeon performed the duty very naturally he ought to be paid the salary, which does not appear to be a very large one; in addition to which there are other duties he is liable to be called upon to perform under the section, and which he may have performed. Accordingly that presentment you will consider and deal with. As regards the other presentment [that for the maintenance of the Infirmary] I have only to repeat that the Act of Parliament makes the approval of the Sessions a condition of the presentment.

The Foreman—That was quite the opinion of the Grand Jury, my lord.

The Grand Jury then withdrew, and unanimously passed the presentment for £47, half year's salary to the surgeon of the infirmary.

We understand that the County Kildare Infirmary will not be closed in consequence of the rejection of the presentment for the maintenance of the institution.

IRISH POOR-LAW INTELLIGENCE.

THE TENURE OF OFFICE OF IRISH POOR-LAW MEDICAL OFFICERS.

THE Irish Local Government Board is at present engaged upon one of those bureaucratic attempts to override the law and the rights of its officers, of which public departments are frequently guilty, when they hope that the proceeding will pass unnoticed, or that the victims will be unable to contend against illegal and oppressive regulations. It will be in the recollection of our readers that the Board recently encouraged a Board of Guardians to deprive of office a workhouse surgeon who had served for thirteen years without any challenge of his efficiency, and whom the Local Government Board itself declared to have merited no such treatment; and they did this act to conciliate the caprice of influential guardians, and to save themselves the responsibility and trouble of a contest on behalf of their own officer. This may appear to be a rash accusation against a public department, but we make it with, as we believe, a full knowledge of the circumstances, and with the conviction that proceedings and motives of the Irish Local Government Board cannot be truthfully expressed in other terms. The warning which we now give to Irish Poor-law medical officers is that the Board is seeking to make the injustice and illegality thus perpetrated towards a single officer a precedent for treating all officers in the same way, and placing them at the feet of the guardians throughout Ireland to be dealt with as the political, religious, or personal tastes of these officials may dictate; and the Local Government Board has already issued a general order under the signature of the Lord Lieutenant, the effect of which is to place all medical officers in this position.

On the 18th of December, 1882, a new general order for the administration of unions was promulgated, which superseded all former orders, and contained the following clauses:—

ARTICLE 40.—The Board of Guardians may, at their discretion, suspend from the discharge of his duties any union officer, except the clerk, chaplain, or treasurer, and shall forthwith report such suspension, together with the cause thereof, to the Local Government Board; and if the Local Government Board shall remove such suspension, such officer shall remain and continue to discharge his duties; but if the Local Government Board shall decide not to remove such suspension, the Board of Guardians may, on being informed of such decision of the Local Government Board, dismiss such officer.

ARTICLE 36.—The salary of every Officer or Assistant appointed to or holding any Office or employment under this Order, shall, subject to the regulations in Article 34, and to the obligation to account to the Auditor, be payable up to the day on which he ceases to hold such office or employment, and no longer; but no officer having been suspended by the Board of Guardians, in pursuance of Article 40, and who shall without the previous removal of such suspension be dismissed by the Local Government Board, or by the Board of Guardians, shall be entitled to any salary from the date of such suspension.

The words which we have italicised are those interpolated in both clauses to enable the Local Government Board to shift the responsibility of dismissal on the boards of guardians. We shall not lose time at present in discussing the unwisdom and the injustice of thus placing the union officer under the foot of the guardian, because the course which the board pursued toward Dr. O'Reilly, of Lismore, has sufficiently proved that this act of the board is influenced not by any sense of its unwisdom or injustice, but by an imperative desire to save itself trouble and responsibility. We do not, therefore, appeal to the Board to act towards their officers as is manifestly right, but we demand that they shall act legally and at least consistently with their own precedents and their own rules, and we regret that the conduct of this public department obliges us to say that it appears insensible to any influence, save a fear of Parliament and of the law courts, and that no redress can be expected from it except by calling into action those powers which are competent to restrain it.

These new rules promulgated by the board are in fact totally illegal and *ultra vires*. The Board has no more power to make them than to dictate orders to the Lord Chancellor, and if it acts under legal advice of any value at all, it must have been told that the Act of Parliament distinctly invalidates any or every attempt to shift the responsibility of dismissal of its officers to any person or body whatever.

There is but one Act of Parliament (the Irish Poor Relief Act of '38) which governs the matter, and the meaning of its provisions do not seem to us to admit of doubt. The 31st section of the Act runs as follows:—

“It shall be lawful for the Commissioners as and where they shall see fit, by their order, to direct the guardians of any union . . . to appoint such paid officers as the Commissioners shall think necessary . . . and the Commissioners may and they are hereby empowered to define, specify, and

direct the execution of the respective duties of such officers, and the places or limits within which the same shall be performed, and direct the mode of the appointment and determine the continuance in office or the dismissal of such officers and the amount and nature of the security, &c. . .”

It will be noted that under this section the Commissioners are to “direct the mode of appointment” (as, for instance, the method of convening the election meeting, the persons entitled to vote, and so forth), and they—and no one else—are to “determine the continuance in office or the dismissal of such officers.” These words of themselves might be considered sufficiently explicit, but they are confirmed by the phraseology of the 33rd section, and by the Order originally made by the Commissioners themselves, and now, with singular inconsistency, reiterated. The 33rd section says :—

“The Commissioners may and they are hereby authorised and empowered as and when they shall think proper by their order, either upon or without any suggestion or complaint on that behalf from the guardians of any union to remove any paid officer appointed under the provisions of this Act whom they shall deem unfit for or incompetent to discharge the duties of any such office, or who shall at any time refuse or neglect to obey and carry into effect any of the orders of the Commissioners, and, in case of the refusal or neglect of the persons competent to appoint, the Commissioners are hereby authorised to appoint, &c.”

It is here set down—one would think—sufficiently clearly that the Commissioners are the persons to dismiss and that the guardians have no power in the matter save to offer “suggestion or complaint” which the Commissioners may or may not give effect to ; and it is to be noted that the officer is liable to dismissal only upon incompetency or unfitness, or for refusal to obey the orders of the Commissioners—it being clearly the intent of Parliament that the officer should not be open to removal because of declining to fulfil the guardians’ orders, or to conform to their personal caprice, and that he should be to that extent, independent of them in the discharge of his duties.

Neither in this clause, nor in any other part of any Act of Parliament that we can find, is there any power whatever given to the Commissioners to delegate dismissal powers to any person or body ; and, indeed, such delegation is contrary to the whole spirit of Irish Poor-law legislation. The Commissioners themselves interpreted the law in this sense, for, acting upon the authority of the law which we have quoted, they made the following rule :—

ARTICLE 39.—Every officer appointed to or holding any office under this Order shall, subject to the provisions of Article 40 of this Order, continue to hold the same until he die, or resign, or be removed by the Local Government Board, and every porter or assistant may be dismissed by the Board of Guardians without the consent of the Local Government Board ; and every such death or resignation, and every such dismissal, and the grounds thereof, shall be reported to the Local Government Board.

It will be noted that herein a marked distinction is drawn between those menial servants which the guardians might dismiss, and those higher officers which the Local Government Board alone was entitled to deal with ; and nothing can be clearer than that that Board, and they alone, have power to remove the higher officers. This rule has been transferred unchanged from the old rules to the new, and its presence in the Order of December 18, 1882,

serves to illustrate the slovenly way in which such documents are drawn up in the offices of the department, and how little confidence may be placed in the legal advice under which the Board acts. Here we find the Board stating that “every officer shall continue to hold office until he die, or resign, or be removed by the Local Government Board,” while the very next rule (which we have already quoted) says that the same officer may be dismissed by a third party.

The view of the law of tenure of office which we have here explained is that taken by the Irish Medical Association in its correspondence with the Local Government Board which we published in our supplement last week ; and that view is supported by the highest authority. The Association has not ventured to move until it took the best advice ; and it has received the following replies to its queries from Mr. Purcell, Q.C., Chairman of Quarter Sessions for the County Limerick :—

1. Counsel will therefore please advise whether the Local Government Board can legally, by sealed order or otherwise, empower a board of guardians to dismiss or suspend the medical officer of the union under any circumstances whatever.

I am of opinion that the Local Government Board have no power to delegate to boards of guardians any authority to dismiss or suspend the medical officer of the union, and that the general orders to this effect in the Articles 39 and 40 of their recent Circular are *ultra vires* and illegal.

2. Should Counsel be of opinion that the Local Government Board (though not being able to delegate their power of dismissal) can legally delegate the power of suspending a union medical officer, can a board of guardians exercise such power of suspension in such a way as to practically dismiss the union medical officer ? And Counsel’s general opinion is requested.

I find no provision in any of the Acts in relation to the power of suspension. In my opinion, neither the Local Government Board nor a board of guardians have power to suspend a union medical officer, or to deprive him of his salary, except from the date of his dismissal by the Local Government Board, and that the provision in Article 36 of the recent Circular as to the deprivation of the medical officer’s salary from the date of suspension is also *ultra vires*.

T. A. PURCELL.

71 Harcourt Street, Dublin,
15th February, 1883.

The reply of the Irish Local Government Board to the representatives of the Irish Medical Association, which we publish to day, is characteristic. It pleads that “the only difference between the new and former orders consists in boards of guardians having now authority to dismiss an officer whose suspension the Local Government Board does not see fit to remove.” In this view of the new law we entirely agree ; but we think that this little “only” clause makes a wonderful difference to the medical officer. It places him at the disposition of a class of persons who, we know by experience, will sacrifice him and his family without mercy if it pleases their religious or political prejudices to do so ; it subjects him to endless annoyance at the hands of people whom he dare not offend, for if he does so, he may, at any time be thrown on the world without employment ; it makes the

honest discharge of his duty impossible, because he cannot afford to tread upon the toes of influential people to whom the Local Government Board has handed the whip for chastisement.

We say advisedly that the new rules have all this pernicious effect, and we say so because we do not consider the protective control reserved to the Local Government Board of any value whatever to the officer. We have only to turn back to the Lismore case, and to many other instances in which the Board has deserted its well-deserving officers in their extremity, to verify the belief that the Board has not the firmness to face a contest with any board of guardians which desires to immolate an officer, or to meet the mildest popular clamour. The Commissions have lately hinted that it is not their business to interfere with the discretion of guardians, and that officers had better take care of themselves if they do not want to be dismissed; and we, therefore, emphatically reject the invitation extended to Irish Poor-law Medical Officers to put their trust in the department under which they act.

The Board has been referred to the sections of the Act of Parliament, as above quoted, and it seeks refuge in the third section of the same Act, which says that—

“The Commissioners are authorised and required from time to time, as they shall see occasion, to make and issue all such orders for the government of workhouses . . . and the poor therein, and for the guidance and control, appointment and removal of the officers thereof, and for guidance and control, according to the intentions of this Act, of all guardians, wardens, and other officers, paid or unpaid, acting on the management or relief of the destitute poor; and the Commissioners may, at their discretion, from time to time suspend, alter, or rescind such orders, or any of them.”

The Board expresses the opinion that this section gives them power to “authorise Boards of Guardians to dismiss certain officers described in the general order,” in which view not only we, but the much higher legal authority of Mr. Purcell, Q.C., entirely disagree. The Board may, under this clause, make any rules it pleases, “according to the intentions of the Act;” but it has no power to make any decree which goes in the smallest tittle against or beyond the words of the law. We do not suppose that the Board would pretend to any right to make a rule which would entitle the guardians to appoint or depose an auditor, or which would authorise the Commissioners to appoint the chairman of the guardians. Every one knows that every Act of administrative law contains a clause enabling the central authority to make rules “according to the intentions” of the law, and every one knows that such clause does not confer upon the central authority any power whatever to depart from the intention of the law under which it acts. The plea thus urged by the Irish Local Government Board is puerile, and we believe it would not stand five minutes before a court of law, and we hope that the Board will see the wisdom of taking better legal advice than that on which it has acted, and—if advised that its rules are *ultra vires*—rescinding them with as good grace as possible. If the Board does not adopt this course, it may reasonably assume that the first case of dismissal by a board of guardians will involve both the guardians and the

Commissioners in a lawsuit and a judicial decision which will not profit the guardians or do credit to the legal acumen of the law adviser of the Irish Local Government Board,

IRISH MEDICAL ASSOCIATION.

REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL,

Read and adopted at a Meeting of the Council, held January 23rd, 1883.

Dr. WHISTLER, of Bray (Vice-President for Leinster), in the Chair.

(Concluded.)

RECOVERY OF FEES ON CANCELLED RED TICKET.

A dispensary medical officer, having been called upon, under the authority of a visiting ticket, to attend a patient whom he considered well able to afford to pay fees, brought the circumstances of the case under the notice of his dispensary committee, who thereupon cancelled the ticket.

The medical officer then sued the patient at Petty Sessions for £1 ls., the amount of his fee, and the justices asked the opinion of the law adviser, who recommended that they should dismiss the case, which they accordingly did. The Committee of Council then took up the case, which was listed for hearing at next Quarter Sessions, and directed that, if it were found necessary, a well-instructed junior counsel, nominated by the Committee of Council, should be specially retained, at the expense of the Association, to plead; and that if the case were unsuccessful, an appeal should be made to have the case tried in the Queen's Bench Division, as the Committee of Council deem it extremely important that the right to recover fees by a dispensary medical officer, upon whom such imposture has been practised, should be, once for all, established by the Supreme Court upon the first opportunity, in order that this form of abuse of the medical charities system may as effectively as possible be prevented.

There are very numerous instances in the Association's records, to which reference can at any time be made, in which claims of this nature have been allowed at sessions and assize courts, and the Committee of Council are not cognizant of any instance of late years in which such claims have been refused. It was therefore believed that the legality of such claims was fully established. However, should occasion arise for contesting the point in the Supreme Court, the Committee of Council are firmly of opinion that such course should be adopted in a spirited manner.

The Committee of Council have just learned, through Mr. Clifford Lloyd, Solicitor to the Association, that the difficulty in the case in question has just been removed by the claim having been settled out of court, the defendant having paid the fee demanded and a portion of the costs, as recommended for acceptance by the local solicitor.

In another instance of a similar nature, occurring in another county, a claim of £2 2s., for professional attendance given on a visiting ticket, which subsequently had been cancelled, was paid before the case came into court—a not unusual result. This case was also taken up by the Committee of Council.

The Committee of Council are advised that cases of this kind should not be brought into Petty Sessions Courts, as there is no appeal from such Courts beyond Quarter Sessions; and that it is advisable that such claims should, in the first instance, be heard at Quarter Sessions or Assize Courts, where, in the event of an adverse decision, it would enable the case to be brought

attend at the workhouse daily to dispense medicines, and to do such other duties as the resident medical officer may direct, at a salary of £80 per annum."

Mr. Shackleton moved the adoption of the report, which, he said, should commend itself to the good sense of the board.

Mr. Hearne seconded the motion.

Mr. Lyons considered that £80 was too small an allowance for a competent apothecary. He suggested that the salary should be £100 per annum.

Mr. Bewley said the committee had made inquiry before fixing the sum, and they believed that a suitable person could be got for £80. If they got a good man, in time his salary might be increased.

Mr. Shackleton thought the parties applying could have confidence in the board, to this extent at least, that the gentleman who would be appointed would, if he discharged the duties satisfactorily, have his salary increased in good time.

Mr. Lyons thought the sooner they made the advance the better. If the guardians offered a reasonable salary at once they would have a better chance of getting a good man.

Mr. Alexander Deane moved that the doctor's salary be £200 only.

Mr. Godley seconded the amendment, which, after some discussion, was withdrawn.

The motion was adopted unanimously.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

Dr. THOMAS JOSEPH MOORE, *examined.*

(Continued.)

1207. In your county you have rather a high class of guardians, have you not?—Yes.

1210. Of course while you have expressed no opinion as to the discretion vested by the proposed Bill in any person you would wish that the Local Government Board should have no more discretion than the poor law guardians?—I am speaking for myself; but if I am to speak for the medical officers, not for any other body, they would prefer that the Local Government Board should have the control as they place such implicit confidence in them.

1211. You think they would prefer it?—Yes.

1212. As long as the officer fulfils his duty without complaint, or without cause for complaint, are you of opinion that there should be no more discretion vested in the Local Government Board than the Poor Law Board, but that the officer should be certain of his pension on doing his duty?—Yes.

1213. And that there should be no power in the Local Government Board any more than in the poor-law guardians to deprive a doctor of his pension, so long as he has performed his duty and fulfilled his part of the contract?—Yes; but it might be that the guardians would have to state that fact to the Local Government Board, and the guardians would first have to satisfy themselves that that was the case.

1214. When you object to giving the guardians discretion to withhold this pension, you would equally object to the Local Government Board having the power to withhold it?—Yes, unless on fair grounds.

1215. And you would give to boards of guardians as well as to the Local Government Board power to withhold the pension if they could bring forward fair grounds for doing so?—If any man merits superannuation let him have it, quite immaterial of where it comes from.

1216. Do you not consider that if an officer has acted in a district for the necessary number of years without complaint, the fact of his having so acted without censure

is a proof that he has fulfilled his part of the contract?—Yes, as a general rule that would be so.

1217. Mr. Daly. You have been 26 years in charge of the Ardee Dispensary?—Yes.

1220. You are responsible to the dispensary committee, are you not?—Precisely.

1221. And you do not come in contact with any member of the board other than the dispensary committee, except at isolated times?—As sanitary officer I am continually with the board; I have to write to them frequently.

1222. I am speaking of personal contact; you have more contact with the members of the dispensary committee than with any other member of the board?—Yes, as regards anything relative to my dispensary.

1224. How many members compose the usual quorum of the dispensary committee?—Two; average attendance, three.

1229. You were interrupted when you said that there was a provision which they looked for, which was the only one they looked for; what was that provision?—That it would be compulsory.

1231. I am only asking you a general question upon it; but I suppose your motive for taking the compulsory superannuation that you would get under the proposed Bill as against the possible larger superannuation that you would get from the board, arises simply from the old adage, that a bird in the hand is worth two in the bush; is not that the general proposition?—Yes.

1232. You say, under the proposed Bill I will get so-and-so, and I would sooner have that than the possibility of trusting to the board?—Yes; a circumstance occurred about three years ago which shook our faith in the guardians very much; they proposed a reduction in all our salaries, and but for the Local Government Board they would have carried it out, and we naturally became more attached to those who took our part than those who attacked us.

1234. You were asked as regards the question of popularity with the board, whether the doctor might not get into conflict as to the question of the red tickets and relief tickets; what I want to ask is this: would there be much chance of a man of ordinary tact getting to loggerheads with his board upon such questions as relief tickets?—It is a frequent source of conflict.

1236. You describe your board as a very liberal board?—Yes.

1237. Do you mean by that when you call them a very liberal board that they would fairly entertain any reasonable claim made to them?—Always; until the time I mentioned, when that incident occurred about reducing the salaries, they gave the greatest consideration to any application made by their officers.

1238. Have you any doubt that after effluxion of time, say when your 26 years has got to 40, if the board were constituted then as it is now, your claim to superannuation would be fairly considered?—It is a difficult question to answer. I fear that I would get no superannuation; by very nice management it might be carried, but I fear that there would not be a general feeling in favour of it in the union.

1240. When you speak of persons who have held on to their office because they would not get a superannuation, although they were incapable and incompetent, do you speak from actual personal observation and knowledge, or from hearsay?—I know three cases of my own knowledge, and one of those only was a doctor, and he had to give in; he was dying of consumption; he came to me and he was under my care, and he would have had to enter the workhouse, but that the Medical Benevolent Society answered an appeal which I made, and granted a sum which enabled the poor man to live with his family.

1241. Was he refused superannuation?—I think he was. I will not be positive, but I know the man was penniless when he came to me.

1242. Do you know the length of time that he had served?—He must have served 10 or 12 years.

1244. Captain Aylmer. With regard to your remark, that you feared, if you stayed there 40 years, and things were the same then as at present, you would not get a superannuation allowance, can you give the Committee any reason why you think you would not?—A very common answer, sometimes given, sometimes falsely, is, "You are too well off; you do not want it."

1245. Do you think, from general information, that there would be a refusal in other dispensary districts?—The guardians refuse, frequently, because they think the man too well off; they sometimes make a mistake in that respect; they did in Dr. Massey's case.

1246. You said that lately you have lost confidence in the guardians on account of a proposed reduction of the salary?—Our faith was shaken in them, because we never dreamed of their doing such a thing.

1247. Do you think that the medical officers in Ireland would prefer to have their cases adjudicated upon as regards superannuation, by the guardians alone, or by the Local Government Board?—I think they would prefer the Local Government Board, because the guardians sitting there as a Board are not so independent as is generally imagined; they are subject to opposition and outside influences that the Local Government Board rise above altogether; the men who would be well disposed to give a pension are afraid to offend their constituents.

1248. You mean to say that the Local Government Board would be independent of local influence?—Yes.

1249. You have said, four or five times, that the medical officers with whom you have consulted, and, in fact, all officers of unions, wished for this Bill, because of the certainty it gave them; in that case, I presume, you would like to leave out the words "not exceeding?"—Yes, it would destroy it altogether.

Mr. J. D. COPE, *examined.*

1251. Chairman. You are clerk of Rathdown Union, are you not?—I am.

1252. How long have you held that position?—I have been 33 years in the service, and I have been connected with Rathdown for over 27 years.

1255. Are you in favour of this Bill?—Yes.

1256. Are you in a position to represent to the Committee the opinion generally of union officers in Ireland in regard to this Bill?—The opinion of the union officers, as gathered by me in my capacity as one of the honorary secretaries of the Union Officers' Association, is, that some measure is necessary to be passed in order to secure superannuation to officers of long and faithful service.

1257. Is it your opinion that the existing system has worked very unfairly with respect to union officers?—To very many of them.

1258. You think that the proposals of the Bill will meet fairly the expectations of the union officers, and they think it a fair proposal?—I could answer that question by stating the views of the association as regards the Bill as originally introduced, and the amendments which the association thought it would be wise for Parliament to adopt in order to secure them a certainty of superannuation.

1259. You are aware that the Government have consented to introduce certain changes into the Bill as it originally stood?—I am aware of that.

1260. And you think that those proposals are fair and equitable to the union officers generally in Ireland?—I do.

1261. You are aware that this morning the Government announced that they would make a further change with reference to the Bill?—I am.

1262. And that they would propose to make it obligatory upon the boards of guardians to grant pensions; to leave to the Local Government Board only the power in regard to the pensions awarded by the boards of guardians which they already have?—Yes.

1263. And you approve of that change?—Yes.

1264. The scale which has all along stood in the Bill, the Civil Service scale, do you approve of that?—I think the union officers should be placed at all events in the same position as the medical officers of unions. Personally, I would not require it, but I am obliged to make that statement owing to representations made to me by several union officers in Ireland, who are now of advanced age, but not of sufficiently long service to enable them to retire upon a fair allowance.

1265. Mr. Daly. When you use the term "officers," what does that include?—All the non-professional officers; all outside the medical officers.

1266. Chairman. As secretary to the Union Officers' Association, I believe you have prepared a table of the special cases of hardship which can be produced under the existing poor law system with regard to pensions?—I have.

1268. Are you aware that several boards of guardians have expressed themselves favourably as to this Bill?—I am aware that many boards of guardians have done so.

1269. Do you know at all how many?—I have made no tabulated statement, but from my recollection of the number of cases I should say above 30 boards of guardians represented their views to the Local Government Board in favour of the Bill. I think about 20 and between 20 and 30 expressed their views favourably to the principle of the Bill, provided that certain amendments were made, such as if the pensions were paid out of the Consolidated Fund, and other amendments. Between 20 and 30 were of that class, and 20 more took no action, but merely marked the petition "Read," and others petitioned against the Bill.

1270. In the cases of the boards of guardians who objected to the Bill, is it not the fact that several boards objected to the Bill because it would throw an additional burden upon the rates?—I believe that was the principal objection.

1273. Mr. Healy. When the honourable Chairman asked you if you approved of the principle of the Bill, you simply said you thought that some amendment of the law was required to give the poor law officers pensions; but you said, as I gather, that you did not approve of the principle of sixtieths, and that the other officers as well as the medical officers should have something added to their years of nominal service?—Yes, that is the opinion of the union officers, that, at all events, they should be placed in the same position as the medical officers, by having a certain number of years added to their years of service, for many reasons. We say that it is unfair to regard us as civil servants amongst which is the advanced age at which poor law officers enter the service. The average ages will probably be between 26 and 30.

(To be continued.)

IRISH MEDICAL ASSOCIATION.

REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL,

*Read and adopted at a Meeting of the Council, held
January 23rd, 1883.*

Dr. WHISTLER, of Bray (Vice-President for Leinster),
in the Chair.

MR. CHAIRMAN AND GENTLEMEN,—The Committee of Council held twelve meetings since the 17th October, when their last report was submitted; and in the same period twelve new members have joined the Association.

A special General Meeting of the Association was held on the 31st October, in compliance with the requirement of the Board of Trade, when the Honourary Secretary read a report setting forth the reasons which led the

Council to advise the incorporation of the Association, and the various proceedings taken towards its accomplishment, which report has been duly circulated amongst the members. The "Articles of Association" and the "Memorandum of Agreement" were then formally adopted, and the Board of Trade duly notified, which was the last step necessary to complete the incorporation of the Association.

The Committee of Council have since adopted a suitable seal for the Association, which is now being made, and is expected soon to be ready for use.

UNION OFFICERS' SUPERANNUATION (IRELAND) BILL.

The Committee of Council have under consideration the best means to be adopted with a view of affording the warmest support of the Association to this measure, which, they have reason to believe, will be introduced in Parliament early in the approaching session.

The Committee of Council will exert every effort in their power to have the desired amendments inserted in the Bill, and they purpose soliciting the support of every member of Parliament, by circular letter, explaining the reasons why the amendments are being sought, and stating some of the grounds on which the passing of the Superannuation Bill is urgently needed.

It having been observed that the Belfast Board of Guardians had adopted a resolution in opposition to the Bill (and had directed a copy of that resolution to be sent to all the unions in Ireland, requesting co-operation with a view to defeat the passing of the Bill), the Committee of Council addressed a letter to that Board, explaining the errors into which it had fallen; and also, by forwarding to the clerk of each union the following circular—in reply to which several favourable communications were received—endeavoured to counteract the step taken by the Belfast Board:—

Royal College of Surgeons,
Dublin, 9th November, 1882.

UNION OFFICERS' SUPERANNUATION (IRELAND) BILL.

SIR,—I am directed by the Council of the Irish Medical Association to request the attention of your Board to the inaccuracy of the following recent resolution of the Belfast Board of Guardians relative to the Union Officers' Superannuation Bill, viz:—

"That, in the opinion of the Belfast Board of Guardians, the present law vesting them with power to grant superannuation allowances to union officers who may from infirmity, incapacity, accident, or old age, be considered entitled thereto, is sufficient for all practical purposes, and has been hitherto found to work satisfactorily and well; and any legislation bearing on the subject which would be calculated to remove this power from the guardians (who are the direct representatives of the people, and who have personal knowledge of all the circumstances of the respective cases), and vest it in the Local Government Board exclusively, would be fraught with universal disadvantage and dissatisfaction to the poor-law ratepayers of this union; and that a copy of the foregoing resolution be forwarded to all unions in Ireland, requesting co-operation."

On the 22nd of July last the Bill above referred to was read a second time in the House of Commons, and ordered to be committed, and the report of the special committee, dated August 11th, 1882, has been published, from which it will be seen that the chairman (Mr. Herbert Gladstone) and the Solicitor-General for Ireland, on the part of the Government, acceded to an amendment originally proposed by the Irish Medical Association, and the Poor-law Officers' Association, by which, instead of the Local Government Board being exclusively vested with the power of granting superannuation allowances, the board of guardians of every union in Ireland shall grant such superannuation allowances to their officers, with the sanction of the Local Government Board.

It, therefore, appears that the statement contained in

the resolution of the Belfast board is inaccurate, as it is not now proposed to take the power from the guardians and vest it in any other body.

The opinion expressed by the Belfast Board of Guardians, viz., "that the present law is sufficient for all practical purposes, and has hitherto been found to work satisfactorily and well," is not borne out by the evidence supplied in the Return (Mr. Meldon) to the House of Commons, No. 74, of the 16th August, 1880, printed 10th February, 1881; nor supported by the evidence taken before the select committee on the Bill, by whom a member of the Belfast Board of Guardians (Mr. Robert Stewart) was heard and examined. The Council consider that his evidence alone conclusively proves that the present law has not "been found to work satisfactorily and well."

The Council gratefully acknowledge that several boards of guardians have been fair and liberal in their awards of superannuation allowances; but it is an incontestable fact that many have not shown adequate consideration of the claims of retiring officers, some boards having gone so far as to make it a rule not to grant such allowances under any circumstances. While some boards generously awarded the maximum after short periods of service, others refused to recognise even the strongest and most pressing claims; and the result has been a very uncertain and unequal recognition of the claims of retiring officers, many of whom have been left wholly destitute or dependent on charity.

It is this uncertainty of reasonable consideration and want of uniformity in the awards which has led to an amendment of the law being sought, and it will be at once seen that the provisions of the new Bill would not be nearly so advantageous to the interests of retiring medical officers as those of the present law, if only the present law were fairly and equally administered by all boards of guardians without exception.

The chief objects of the Bill, as at present constituted, are to assimilate the superannuation of poor-law officers to that provided for by the "Civil Servants' Superannuation Act," which stipulates that the amount allowed shall be fixed according to a definite and very moderate scale.

The Council would also direct special attention to the fact that it is proposed to provide the necessary funds for this purpose by a rate for the whole of Ireland, to be struck annually by the Local Government Board, so that guardians paying superannuation allowances to any of their officers will be refunded the amount by the Local Government Board, instead of having it charged to the union rates as heretofore.

In connection with this subject, the evidence given before the select committee by Mr. Henry Robinson, C.B., Vice-President of the Local Government Board, may be of interest to your board. He stated that, in his opinion, the cost of the proposed changes would in the aggregate be about the same as at present, although at first there might be a slight increase in the number of pensions; yet, as they would be governed by the Civil Service scale, the total amount of money paid would not be greater than at present. He also stated that the cost of pensions last year would only amount to a rate of 1-32nd of a penny in the pound in the valuation.

In conclusion, the Council desire to express a hope that your board will be pleased to give the "Union Officers' Superannuation (Ireland) Bill" its warm support, as it is calculated to prove economical to the ratepayers, and satisfactory to the boards of guardians and their officers, by providing a uniform system which will not be capable of abuse, either in the direction of extravagance or injustice.

I am, Sir,

Your obedient servant,

JOHN H. CHAPMAN, Hon. Secretary.

To the Clerk of each Union.

(To be continued.)

IRISH POOR-LAW INTELLIGENCE.

IMPORTANT TO DISPENSARY DOCTORS.

THE Hon. Sec. of the Athlone Dispensary Committee has received the following copy of a letter from the Local Government Board :—

SIR,—I am directed by the Local Government Board for Ireland to acknowledge the receipt of your letter and of its enclosures relative to the refusal of Dr. White to act as temporary substitute for Dr. Langstaff, the medical officer of the Athlone Dispensary District, and requesting to be informed how you are to act under the circumstances, and whether the committee of management can appoint a substitute at Dr. Langstaff's expense, and in reply, I am to inform you that the board of guardians would not be authorised in making any deduction from Dr. Langstaff's salary so long as he continues in office. The committee of management should, however, make provision for attendance on the sick poor pending Dr. Langstaff's resignation, or his return to discharge his duties, and the Local Government Board presume that under these circumstances the guardians will, if necessary, agree to pay a temporary substitute for Dr. Langstaff, who has been on leave for an unusually long period.

By order of the Board,

W. D. WORDSWORTH, Assistant Sec.

To John McDonnell, Esq., Hon. Sec.
Athlone Dispensary Committee.

IRISH POOR-LAW SUPERANNUATION.

REPORT OF THE EVIDENCE GIVEN BEFORE THE SELECT COMMITTEE OF THE HOUSE OF COMMONS, 10TH AUGUST, 1882.

DR. THOMAS JOSEPH MOORE, *examined.*
(Continued).

1274. I gather that the principle of sixtieths is in your view objectionable to the union officers outside the medical officers ; would you prefer fiftieths ?—I think the sixtieths would be a fair proportion to give, with the number of years stated in Clause 6 added.

1277. With regard to the existing superannuation enactments, do you think that the officers generally would prefer the option of retiring under the old legislation or under the new ?—Most decidedly under the new.

1278. In any case would it be desirable to allow them an option ?—No, the officers prefer the certainty of having superannuation granted to them according to the scale laid down by the Bill, with the 10 years added.

1279. As between the Local Government Board and the Board of Guardians having this power, which do you prefer ?—It is immaterial to the Association what machinery is employed so long as security is given to the officers, and superannuation awarded them after long and faithful service.

1280. You mean to say if a man is to get £5, it does not matter out of whose pocket it comes, but that is not my point ; supposing it is left optional, do you prefer to deal with the Local Government Board or with the guardians ?—So far as my own board is concerned, to me it is immaterial, but the union officers would have more faith and confidence in the Local Government Board.

1281. Mr. Daly : The honourable chairman elicited from you that many boards of guardians were in favour of the Bill, and you went on further to say that there were 13 boards of guardians in favour of the Bill as originally introduced ?—Yes.

1282. And that 20 were in favour of it, providing the pensions come out of the Consolidated Fund ?—Yes.

1283. Then, strictly speaking, they are not in favour of the Bill, because the Bill does not propose that ?—I take it that they were in favour of the principle of the Bill, that is making the measure a compulsory one upon boards of guardians.

1284. In fact what they did express themselves in favour of, was that the pensions should come out of a Consolidated Fund, and that was not in the Bill ?—I do not think I made myself clearly understood ; what I gathered from the union officers was this : where the boards of guardians approved of the Bill, provided the pensions were paid out of the Consolidated Fund, they approved of the principles of the Bill, that is to say, they approved of the measure being compulsory.

1285. Was not their approval simply this : we will be generous if it costs us nothing ?—It comes to that I believe.

1286. Then there were 20 that took no action at all ?—Twenty took no action at all.

1287. You have only accounted for 70 out of 163 ?—In considering over the question I think I have underrated it in my calculation ; between the guardians who petition in favour of it, and those who took no action, and those who stated their willingness to accept the principle of the Bill, provided the pensions were paid out of the Consolidated Fund, there would be 90 unions out of 163.

1288. Then, in effect, you are not able to answer the question of the Chairman, that anything like a moiety of the boards of guardians were in favour of the Bill as it stands ?—Only in the manner in which I have represented to you.

A LIVELY sensation appears to have been produced in Paris by a statement that some of the sulphate of quinine supplied to the French hospitals contains as much as 43 per cent. of cinchonine. *L'Union Pharmaceutique* throws the blame upon the system which allows the public service to be supplied with foreign quinine by contractors who are incapable of detecting a fraudulent substitution if they wished to do so.

an appeal before the Supreme Court, where it would have a thorough hearing.

Any member of the Association feeling aggrieved in consequence of being called on, under the Dispensary system, to attend a case for which he undoubtedly ought to be paid for his services as a private practitioner, should immediately get the ticket cancelled by the Dispensary Committee, and then, if desirous of recovering his fees, forthwith communicate all the particulars of the case to the Hon. Secretary of this Association before initiating legal proceedings on his own account.

The Committee of Council understand that it is their duty to take up all such cases of unquestionable merit, and to have them conducted to their final issue at the expense of the Association, provided the case be managed strictly in accordance with their instructions.

NEW MEMBERS OF COUNCIL.

In compliance with the direction given at last meeting of Council, the Committee of Council have appointed Dr. Usher, of Dundrum, Co. Dublin, and Dr. Mackesy, of Waterford, to the two vacant seats in the Council, and they invited Dr. Austin Meldon, of Dublin, a member of Council, a compliment which he duly acknowledged with an expression of regret that his professional arrangements would prevent his being able to attend the meetings; consequently, the vacant seat in the Committee of Council has yet to be filled.

THE TENURE OF OFFICE OF WORKHOUSE OFFICIALS.

THE following communication in reference to the correspondence which we published last week has been received by the Irish Medical Association from the Local Government Board. The subject is fully dealt with in our issue of to-day :—

Local Government Board,
Dublin, March 22nd, 1883.

SIR,—The Local Government Board for Ireland have had under consideration your letter of the 8th inst., respecting terms of Articles 36, 39, and 40 of the Board's General Order of Dec. 18th, 1882, relating to the suspension of certain union officers from the discharge of their duties, and their dismissal from office, and in reference thereto the Board desires to call the attention of the Council of the Irish Medical Association to that part of Sec. 3 of Irish Poor Relief Act, 1838, which authorises the Board from time to time to make orders *inter alia* for the appointment and removal of workhouse officers. In pursuance of this enactment, general orders were made in the years 1839, 1844, and 1852, and in every one of those orders the guardians were given authority to dismiss certain officers, and, at their discretion, to suspend others from the discharge of their duties. No power in regard to the suspension of officers has been given to boards of guardians by the recent order in addition to what they possessed before, and the Local Government Board are unable to concur in the opinion which the Council appears to entertain that this order makes a medical officer's tenure of office dependent on the good will of the majority of the guardians, as the Board retains the power to remove the suspension, in which case the medical officer would remain and continue to discharge his duties. The only difference between the new and former orders consists in the board of guardians having now authority to dismiss an officer whose suspension the Local Government Board does not see fit to remove, and whose dismissal they approve of, and the Board are advised that they are fully warranted in making the regulation by the terms of the 3rd section of the Irish Poor Relief Act. The Local Government Board must dissent from the views of the Irish Medical

Association as to the construction and intention of the 33rd section of the Irish Poor Relief Act; that section enables the Local Government Board, if necessary, to act independently of a board of guardians, and to overrule their action in regard to the dismissal of an officer, but it does not deprive the Local Government Board of the power they possess under the 3rd section of the Irish Poor Relief Act to authorise boards of guardians to dismiss certain officers described in their General Order. The Local Government Board made the Order of 18th Dec., 1882, after very careful consideration and under legal advice, and they are not prepared at present to cancel their Order and to issue an amended one as requested.

I have the honour to be, Sir,
Your obedient servant,

W. D. WADSWORTH, Sec.

THE MEDICAL BILL.

THE following petition in favour of the Bill was presented last week by the Irish Medical Association :—

To the Right Honourable the Lords Spiritual and Temporal in Parliament assembled, the Petition of the President and Council of the Irish Medical Association

Most humbly sheweth—

That your Lordships' petitioners are the executive body of an incorporated Association, which numbers amongst its members more than one-third of the entire body of registered medical practitioners in Ireland, and which, for more than forty years, has been maintained in order "to unite the members of the medical profession in Ireland, and so form a body competent to exercise influence in sanitary and medical affairs for the public benefit, and to protect and promote the interests of the medical profession."

That your Lordships' petitioners have considered the provisions of the Medical Acts Amendment Bill, now standing for a second reading before your Right Honourable House, and fully approve of the principles of said Bill.

That the Irish Medical Association has, at many successive annual general meetings, declared its approval of the proposals—

a. To restrict the privilege of registration as a medical practitioner to persons who shall have passed before a Central Examining Board for each division of the Kingdom an examination adequate to ensure their competency, registration being granted throughout the Kingdom upon equal terms as regards standard of examination, duration of study, and amount of fees payable prior to examination.

b. To reconstitute the General Medical Council, so that an adequate direct representation therein of the registered medical practitioners throughout the Kingdom shall be secured.

c. To amend the existing law so as to check effectively the practice of medicine and the improper use of medical titles by unqualified persons.

That your Lordships' petitioners are aware great abuses have arisen in the granting of licences to practise medicine, and great injury has arisen to the public from the difficulty of distinguishing between competent and incompetent practitioners by reason of the inefficacy of the existing law.

That your Lordships' petitioners therefore humbly pray that your Most Honourable House will be pleased to pass said Bill.

(Signed)

JAMES MOLONY, President.
JOHN H. CHAPMAN, Hon. Sec.

IRISH POOR-LAW INTELLIGENCE.

POOR-LAW SUPERANNUATION (IRELAND) BILL.

THIS Bill stands for a second reading, and only waits for an occasion when the notice-paper of the Commons is clear enough to enable it to come on before midnight. After that hour it cannot, by the rules of the House, be taken, because the delectable member for Cavan, Mr. Biggar, and Mr. Richard Power, member for Waterford, have "blocked it"—i.e., given notice of a motion that it "be read a second time this day three months," which is the Parliamentary way of expressing rejection. Every effort has been unavailingly made to induce these gentlemen to take off the block, and therefore there is no way over the difficulty save for Mr. H. Gladstone to get the Bill put high up on the notice-paper, and fight it out with the Obstructives, who, we believe, are in a helpless minority. Unfortunately, this is not easily managed, and the Affirmation Bill has made it impossible for the present; but after Whitsuntide progress may be hoped for.

THE H. H. H. STEWART BEQUEST.

THE Master of the Rolls for Ireland—Sir Edward Sullivan—has recently given judgment as to the disposition of the estate left by the late Dr. Henry Hutchinson Stewart. Dr. Stewart occupied a remarkable position in the medical history of the last half century. He held the position of governor of the House of Industry, a sort of industrial institution which existed fifty years ago in Dublin, and which has since been converted into the House of Industry Hospital, by which name the Richmond (surgical), Whitworth (medical), and Hardwicke (fever) are now known. On the introduction of the Irish poor relief system, the House of Industry was abolished, and a number of the pauper lunatics were confided by Government to the care of Dr. Stewart, who maintained them at first at Island Bridge, near to Phoenix Park, and afterwards at Lucan, about six miles from Dublin. In this way, Dr. Stewart became the proprietor of a large asylum at Lucan, and amassed a considerable fortune, part of which has now been disposed of by the Master of the Rolls. Dr. Stewart's name will live in the memory of our profession as that of one of its most benevolent members. His first act after his retirement from active life was to hand over the valuable and spacious premises at Lucan, a free gift towards the foundation of the "Stewart" Institution for Imbeciles and

Lunatics, and at the same time he gave a large donation towards erecting a suitable building. After that time it was Dr. Stewart's habit to live in the most sparing manner, and to hand over to charity immediately the money thus saved by the sacrifice of his own pleasures. In this way he presented considerable sums from time to time to the Royal Medical Benevolent Fund Society in Ireland, and other charities, but his benevolence in this way did not prevent his leaving, after his death, a sum of about £18,000. Respecting this sum, he left only very indefinite instructions, and the Master of the Rolls was, therefore, called upon to dispose of the funds. To the Stewart Institution he gave a sum of about £2,000, sufficient to wipe off an old-standing debt due by the Institution to Dr. Stewart, and the balance he set aside for the endowment of medical scholarships in the University of Dublin and the Royal Irish University. We cannot but regret that the learned judge should have selected this method of disposing of Dr. Stewart's money. He might with great advantage have endowed the Irish Medical Benevolent Fund, with which for many years Dr. Stewart had been closely associated; or he might, if he considered himself restricted to medico-educational objects, have found many worthy purposes to which the money might have been given. The learned judge could hardly have found a purpose less consistent with the testator's wishes or with the interests of the public and the profession than those he has selected. Indeed, considering that the University of Dublin is wealthy enough to pay for any number of medical scholarships, and that the Royal Irish University is a State-supported institution, we can hardly imagine a less useful appropriation of Dr. Stewart's money than the handing it over to these institutions. If the benevolent testator could have known the object to which his savings would have been given, we are confident he would not have left a shilling of his money undistributed.

THE IRISH MEDICAL ASSOCIATION AND THE MEDICAL BILL.

THE following Memorial was presented last week to the Lord President of the Council by Dr. Jacob, on behalf of the Irish Medical Association:—

TO THE RIGHT HONOURABLE THE LORD PRESIDENT OF THE PRIVY COUNCIL.

The Memorial of the President and Council of the Irish Medical Association.

Humbly sheweth—

That your Lordship's memorialists having urged upon your Lordship the necessity for legislation for amendment of the Medical Acts, acknowledge with satisfaction and thankfulness the efforts of Government to promote such legislation, and have petitioned the House of Lords in support of the principles of the Medical Bill.

That your Lordship's memorialists nevertheless view with regret the proposal of the constitution of the Medical Board for Ireland contained in clause 9, subclause 5 of the amended Bill, inasmuch as it is therein proposed to exclude the directly elected representative of the medical practitioners of Ireland, and to give to the King's and Queen's College of Physicians only two representatives on the same Board.

That it is the opinion of your Lordship's memorialists it would be both unjust and inexpedient to exclude from consideration of Irish medical arrangements the representative of the medical practitioners in Ireland, and to limit the influence of that representative to the part which he may take in a meeting or meetings of the Medical Council for a few days in each year.

That without desiring to enter into a comparison of the respective claims of the medical authorities to be represented in said Board, your memorialists feel it their duty to give emphatic expression to the opinion that the licensing corporations of Ireland are by the extent of their work in medical education and qualification, by the high standard of curriculum and examination which they have maintained, and by the regard which they have shown for the general education and culture of their licentiates, fully entitled to an influence in the Medical Board equivalent to that secured to the Irish Universities by the Bill, and that the College of Physicians is in no respect deserving of less influence upon Irish medical affairs than any of the other medical authorities.

That your Lordship's memorialists consider the proposed method of election of the members of the Medical Board altogether objectionable, because in most instances it does not provide for the true representation of the constituents of the electing body, but vests the elective power in governing authorities which are frequently self-appointed, and are seldom so constituted as to be entitled to speak on behalf of the constituency. Your Lordship's memorialists are therefore strongly of opinion that clause 54, lines 29 to 32, page 30, ought to be so altered as to vest future power of election in the Fellows, Medical Graduates, or other medical corporate voters of the body entitled to return the delegate.

Your Lordship's memorialists therefore humbly pray that Her Majesty's Government will be pleased to give their support to the proposition for the amendment of the Bill in the direction above indicated.

Signed on behalf of the Irish Medical Association,

JAMES MOLONY, F.R.C.S.I., President.

JOHN H. CHAPMAN, F.K.Q.C.P.I., Hon. Sec.

LIST OF ENTRIES IN THE REGISTER OF THE
BRANCH MEDICAL COUNCIL (IRELAND) FOR
THE MONTHS OF FEBRUARY AND MARCH, 1883.

FEB. 1st.—Gowland, J. W.; Newton House, Rathgar; M.B. and Bac. Surg. Univ. Dub. 1882.

1st.—Martin, W. A. P.; Markethill, co. Armagh; M.D. R. Univ. Irel. 1882.

13th.—Alcorn, S. A.; New South Wales; M.B. and Bac. Surg. Univ. Dub. 1883.

14th.—Concannon, Austin; Tuam, co. Galway; Lic. R. Coll. Phys. & Surg. Edin. 1883; L.A.H. Dub. 1882.

14th.—Carry, W. W. S.; St. Mark's Hosp., Dublin; Lic. R. Coll. Surg. Irel. 1882; L.A.H. Dub. 1883.

14th.—Fetherstonhaugh, W.; 2 Belgrave Square West, Monkstown; Lic. R. Coll. Surg. Irel. 1879.

16th.—Curtis, J. H.; 7 Camden Place, Cork; Lic. R. Coll. Phys. & Surg. Edin. 1883.

16th.—Peet, F. F. Tralee; Lic. R. Coll. Surg. Irel. 1882.

17th.—Graham, S.; Legoniel, co. Antrim; Lic. R. Coll. Phys. Lond. 1883.

23rd.—Torney, G. P.; 8 Blackball Street, Dublin; Lic. R. Coll. Surg. Irel. 1882.

27th.—Finegan, J. P.; Kingscourt, co. Cavan; M.B. and Bac. Surg. Univ. Dub. 1883.

MARCH 1st.—Lane, Thomas; 127 Leinster Road, Dublin; Lic. R. Coll. Surg. Irel. 1882; Lic. K. Q. Coll. Phys. Irel. 1883; Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

7th.—Heffernan, Geo. B.; 22 Charleville Road, Rathmines, co. Dublin; Lic. R. Coll. Surg. Irel. 1882.

28th.—Howard, Timothy; 9 Herbert Road, Sandymount; Lic. R. Coll. Surg. Irel. 1882; Lic. & Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

28th.—Gormley, J. W.; Peter St., Drogheda.

28th.—Cruise, F. J.; 93 Merrion Square West, Dublin; Lic. R. Coll. Surg. Irel. 1882.

UNION OFFICERS' SUPERANNUATION BILL.

Abstract of a Bill to make better provision for the Superannuation of the Officers of Poor-law Unions in Ireland.

Introduced April 5, 1883, by Mr. Herbert Gladstone, Mr. Trevelyan, and the Attorney-General for Ireland.

BE it enacted, &c.

1. This Act may be cited as the Union Officers' Superannuation (Ireland) Act, 1883.

2. *Grant of Superannuation.*—From and after the passing of this Act the board of guardians of every union in Ireland shall, with the sanction of the Local Government Board for Ireland (in this Act called "the Local Government Board"), grant to any union officer belonging to that union who shall become incapable of discharging the duties of his office with efficiency by reason of permanent infirmity of mind or body or of old age, upon his resigning or otherwise ceasing to hold his office, a superannuation allowance, according to the following scale—that is to say—

To any officer who shall have served in some one or more unions in Ireland for ten years and upwards, and under eleven years, an annual allowance of ten-sixtieths of the annual salary and emoluments of his office:

For eleven years and under twelve years, an annual allowance of eleven-sixtieths of such salary and emoluments:

And in like manner a further addition to the annual allowance of one-sixtieth of such annual salary and emoluments in respect of each additional year of such service until the completion of a period of service of forty years, when an annual allowance of forty-sixtieths shall be granted, and no addition shall be made in respect of any service beyond forty years.

No officer shall be entitled to such allowance on the ground of age who shall not have completed the full age of sixty years, and shall not have served as a union officer in some one or more unions in Ireland for twenty years at the least.

For the purposes of this section, the annual salary and emoluments of a union officer shall be calculated on the average of the three years ending with the quarter-day next before he ceases to hold his office.

No officer shall be entitled to any superannuation allowance or gratuity under this Act unless the Local Government Board are satisfied that he has discharged his duties as a union officer with diligence and fidelity.

3. *Allowance in Cases of Bodily Injury.*—The board of

guardians of any union, with the sanction of the Local Government Board, may, if they think fit, grant to any person, being the holder of a union office in the union in respect of which a superannuation allowance might be granted under this Act, who, before the completion of the period which would have entitled him to a superannuation allowance, is compelled to quit the service of the union by reason of severe bodily injury occasioned, without his own default, in the discharge of his duty as a union officer, a gratuity not exceeding three months' pay for every two years' service, or a superannuation allowance not exceeding ten-sixtieths of the annual salary and emoluments of his office; and may, if they think fit, with the like sanction, grant to any such holder of a union office who is compelled from infirmity of mind or body to leave the union service before the completion of the period which would have entitled him to a superannuation allowance, such sum of money as the board may think proper, but so that no such gratuity shall exceed the amount of one month's pay for each year of service.

4. *Local Government Board may Reduce any Pension.*—Whenever an application is made to the Local Government Board to sanction the grant to any union officer by a board of guardians of a superannuation allowance or gratuity under this Act, it shall be lawful for the Local Government Board either to sanction or to refuse to sanction such grant, or to sanction the grant of a superannuation allowance or gratuity to such officer of such less amount than otherwise would have been awarded to him as the Local Government Board may determine, where the defaults or demerit of such officer in relation to the union service appear to them to justify such diminution.

5. Every superannuation allowance or gratuity granted under this Act shall be payable to, or in trust for, the union officer, and shall not be assignable nor chargeable with his debts or other liabilities.

6. *Discontinuance of Pension in certain Cases.*—In case any person enjoying any superannuation allowance under this Act is appointed to be a union officer in any union, every such allowance shall cease to be paid so long as he continues to hold such appointment if the annual amount of the profits of the office to which he is appointed are equal to those of the office formerly held by him; and in case they are not equal to those of his former office, then no more of such superannuation allowance shall be paid him than with the salary of his new appointment shall be equal to that of his former office.

7. *Provision for Cases of Professional Qualification.*—The Local Government Board may from time to time, by order, declare that for the due and efficient discharge of the duties of any union office or class of offices to be specified in such order, professional or other peculiar qualifications are required, and that it is for the interest of the public that persons should be appointed thereto at an age exceeding that at which public service ordinarily begins; and may, by the same or any other order, direct that when any person holding any such office shall retire from the union service, a number of years not exceeding ten, to be specified in the order, shall, in computing the amount of the superannuation allowance which may be granted to him under this Act, be added to the number of years during which he may have actually served.

8. The Local Government Board may from time to time make rules with reference to the mode in which a union officer shall establish what his age is, and establish that he has discharged his duties with diligence and fidelity, and with respect to any other conditions the fulfilment of which the Board may require to be proved; and in the case of an officer retiring on the ground of infirmity of mind or body, if the Board by any such rules require the officer to appear for examination before a medical board, or before a medical practitioner nominated by the Local Government Board, the Local Government Board may defray the expenses of such examination out of the superannuation fund provided by this Act.

9. All allowances and gratuities payable under this Act shall be advanced from time to time by the board of guardians of the union in which the officer was serving at the time of his ceasing to be a union officer, and shall be repaid to the board of guardians out of the union officers' superannuation fund.

For the purpose of providing for such repayments, the following enactments shall take effect:—

(1.) On, or as soon as conveniently may be after, the first day of January in every year after the passing of this Act, the Local Government Board shall estimate what sum will be necessary for the purposes of this Act during the year.

In making the first of such estimates under this Act, the Local Government Board shall estimate what sum will be necessary for the purposes of this Act during the whole of the period between the passing of this Act and the first day of January next following the making of the estimate.

The Local Government Board shall in each year, by order under their seal, assess that sum on the several unions in proportion to the net annual value of the property therein. They shall send copies of the order to the guardians and to the treasurer of each union.

(2.) Thereupon the treasurer shall, if he has then in his hands to the credit of the guardians sufficient funds, pay the amount so assessed into the Bank of Ireland; and if he has in his hands to the credit of the guardians funds not sufficient for payment in full of the amount so assessed, he shall pay into the Bank of Ireland such balance as he may have in his hands in reduction of the amount so assessed; and in such case, or if he has no funds in his hands to the credit of the guardians, then he shall, out of all moneys subsequently received by him on account of the guardians, pay the amount assessed into the Bank of Ireland. Moneys paid into the Bank of Ireland under this Act shall be placed to the credit of the Local Government Board, to the account of a fund which shall be called the Union Officers' Superannuation Fund.

The guardians of each union shall debit the several electoral divisions with proportions of the sum assessed upon the union, according to the net annual value of the property in each division.

(3.) On the 25th day of March, 1884, and on every 29th day of September and 25th day of March following, the guardians of each union shall furnish to the Local Government Board accounts of the moneys expended by them for superannuation allowances and gratuities payable under this Act since the date of the last preceding account, or, in the case of the accounts furnished on the 25th day of March, 1884, since the date of the passing of this Act; and the Local Government Board shall pay to the treasurer of the union, out of the union officers' superannuation fund, the amount mentioned in the account furnished by the board of guardians of the union when such amount has been found to be correct.

10. In this Act the term "union officer" includes every person appointed by the board of guardians of any union to be a permanent officer of the union under the provisions of the 31st section of the Act of the session of Parliament of the 1st and 2nd years of the reign of Her present Majesty, chapter 56, and the 4th section of the Act of the session of Parliament of the 10th year of the reign of Her present Majesty, chapter 31, whether such officer is paid by wages, poundage, or percentage on collection of rates, or by a salary; and also every chaplain of a union, and every medical or surgical officer of a union, or of any dispensary district therein; and every person appointed or constituted as sanitary officer under the 11th section of the Public Health (Ireland) Act, 1878, or clerk to the burial board of any district where such burial board is a board of guardians, or clerk to the local authority acting in execution of the Contagious Diseases

(Animals) Act, 1878, where such person has been so appointed by a board of guardians, or holds his office as a sanitary officer, or clerk of the burial board, or clerk of the said local authority, by virtue of any other office to which he has been appointed by a board of guardians; and also the registrar of births, deaths, and marriages in every union, and the superintendent registrar, being also the clerk of the union.

The term "emoluments" includes all fees, poundage, and other payments made to a union officer for his own use, as such union officer out of poor rate or sanitary rate, or money voted by Parliament; and also the money value of rations, apartments, and other remuneration appertaining to the office held by such union officer, estimated according to such scale or in such manner as the Local Government Board shall prescribe.

11. The Acts specified in the schedule to this Act are hereby repealed so far as they relate to the superannuation of any officer who retires from his office after the passing of this Act.

This repeal shall not affect the powers of the board of guardians of any union with reference to the granting of a superannuation allowance under any of the said Acts to an officer who has retired from his office before the passing of this Act; nor anything duly done or suffered, nor any right or liability acquired, accrued, or incurred, under any enactment hereby repealed; and shall not relieve the board of guardians of any union from the obligation to pay any superannuation allowance granted by them under any of the said Acts.

SCHEDULE (referred to in Section 11).

Session and Chapter.	Title or Short Title.
28 & 29 Vic., c. 26.	An Act to provide for superannuation allowances to officers of unions in Ireland.
32 & 33 Vic., c. 50.	The Medical Officers' Superannuation Act (Ireland), 1869.
35 & 36 Vic., c. 89.	An Act to amend the Act providing superannuation allowances to officers of unions in Ireland.

CORONERS' SALARIES.

At the recent Commission of Assize for Queen's County, Chief Justice Morris presiding in the Crown Court, the question of coroners' salaries was brought before his Lordship.

Dr. Higgins, the coroner for one of the divisions of the county, applied to the Grand Jury for a presentment for £52, half a year's salary, and £6 for three inquests held out of his division. Dr. Quirke, the coroner for the other division, also applied for £52, half a year's salary. It appears that upon the passing of the Act commuting the paying of coroners by fees to payment by salary, the coronerships for the county were held by the late Mr. Clarke and Dr. O'Kelly. The Act provides that the salary fixed shall be based on the amount of fees paid to the coroner or his predecessor for five years previous to the passing of the statute. About seven years before the passing of the Act, Dr. O'Kelly went to reside out of the county, and the Grand Jury found that they could not present for his fees under the circumstances. The consequence was that though Dr. O'Kelly had not resigned his appointment he did not hold any inquests during the five years previous to the passing of the Act, and the work of the entire county was consequently done by Mr. Clarke. A committee of the Grand Jury fixed Mr. Clarke's salary—upon the work of the entire county—at £104, and no salary was fixed for Dr. O'Kelly. Upon Mr. Clarke's death Dr. Higgins was elected coroner for the division held by the deceased gentleman, and claims the amount of salary Mr. Clarke received. Dr. O'Kelly held office for some short time after Mr. Clarke's death, still doing no

work. He subsequently resigned, and Dr. Quirke was elected to his division. Dr. Quirke also claims a salary of £104 a year. The Grand Jury threw out both presentments, in order that the question might be brought before the judge.

The question having been argued at some length, his Lordship said it appeared to him the Act of Parliament had been framed without a full knowledge of the subject, as this case exemplified. No provision was made for contingencies. He was only putting a reasonable interpretation upon the Act when he said that a "predecessor in office" was the person who previously held the post. Accordingly, Dr. Quirke was entitled to Dr. O'Kelly's salary, which was *nil*. The Grand Jury had passed a resolution of remonstrance on this subject at the last July assizes. The Act of Parliament was his master in the matter, and he must abide by it. He would therefore pass the presentment at £104 for Dr. Higgins.

ELECTION OF MEDICAL OFFICER FOR HEADFORD DISPENSARY DISTRICT

A MEETING of the Dispensary Committee for Headford district was recently held for the purpose of electing a medical officer in room of Dr. J. C. Flood, then resigned. The result was a tie, ten having voted for Dr. Charles J. Blake, of Tuam, and ten for Dr. James Gorham, of Letterfrack, the only candidates nominated. Mr. O. Flaherty there and then objected to the votes of two members of the committee, inasmuch as one had been adjudicated a bankrupt, and the other was not a rated occupier in the district; and on these grounds claimed the election for Dr. Blake. Dr. Gorham made a counter objection, representing the proceedings to have been illegal, one of the Poor-law guardians not having been notified to attend the election. All objections and protests for and against were forwarded to the Local Government Board, but that body not having determined the issue one way or the other, the committee recently appointed met on Tuesday when Dr. Blake and Dr. Gorham again entered the lists, and the former was returned by a majority of two. In appointing committee the week before last some changes were made.

It being put to a poll, there voted for Dr. Blake, 12. For Dr. Gorham, 10.

The chairman declared Dr. Blake duly elected.

Dr. Blake briefly returned thanks, whereupon the proceedings terminated.

EXTIRPATION OF THE COCCYX.

THIS operation was done by Marie B. Werner, M.D., Philadelphia, in the case of a married woman who came under her care for intolerable backache, which was always aggravated in the act of sitting down, or resuming the erect posture. On examination the extremity of the coccyx was found to be very painful, and turned to the right. The patient had suffered from this pain for a year and a-half, since her last confinement. It was determined in consultation that mere division of the ligaments would not suffice, so extirpation of the bone was resolved upon. The patient made a good recovery. There was a good deal of interference with the power of making water until the patient was able to be up and about again. Acute pain of a throbbing, stinging, and cutting character was felt on the third day, but this was relieved by the removal of the three stitches by which the wound was closed, and which had been introduced deeply to keep the parts well together. Some pain and soreness remained for six weeks after removal of the bone, but this gradually subsided. The free extremity of the bone was found to be the seat of commencing osteitis.

IRISH POOR-LAW INTELLIGENCE.

IRISH COUNTY INFIRMARIES' GRANTS.

We print to-day a very important discussion and judicial decision with reference to the grant for the County Kildare Infirmary, from which it appears to be the law—

a. That the Grand Jury have no power to present a sum for the maintenance of a county infirmary unless at the Presentment Sessions the cesspayers have previously assented to a grant of greater or less amount.

b. That notwithstanding the withdrawal of the grant for the infirmary, the Grand Jury may vote payment of the salary of the surgeon.

It is unnecessary to speculate upon the reasons which led to the distinction between the two presentments. Possibly, as Chief Justice Morris said, it was considered advisable to reduce to a minimum the chances of the rejection of the presentment for the surgeon's salary, because the surgeon is in certain cases compelled to discharge gratuitously duties which do not appertain to the infirmary of which he is the medical officer, or possibly it was considered just to protect the surgeon from the injustice of being deprived of payment for services rendered. If the Legislature apprehended that the sessions might, if their approval were made a condition of the presentment, some day or other decline to remunerate the surgeon for work he had already done, their suspicions regarding popular notions of fair play were not without justification; for had not the Kildare Grand Jury been competent to make presentment for Dr. Chaplin's salary without the assent of the sessions, the surgeon of the Kildare Infirmary would have been deprived of remuneration for services extending over some months.

We have already expressed on many occasions, and we now reiterate our great regret to observe the existence and growth of hostility to the county infirmaries on the part of those who call themselves "the popular party." We do not in the least dispute their moral or legal right to refuse to expend the county cess on these institutions, but we believe that if they calmly considered the subject they would not adopt any such course. In the first place we think that any one who looks at the matter from a non-political standpoint, and in the public interest, will agree with us that the abolition of the Irish County Infirmary would be a grievous loss to a numerous section of the popular party, and would involve the withdrawal of a considerable amount

of money contributed by private charity for sick relief, and would therefore entail an increase in the expense of providing that sick relief at the public cost. We most earnestly deprecate any invidious comparison between the workhouse hospital and the county infirmary to the disfavour of either. Each has its scope and use. The union hospital is indispensable for the care of the infirm and destitute, and for the reception of those patients who are not unwilling to enter the union.

The county infirmary, on the other hand, has its very important function in ministering to the wants of the more acute and temporary cases of disease amongst the small farming class, who, while incapable of paying for medical attendance in idleness and at home, are not to be blamed if they object to pauperise themselves and their families by entering the union. In England these cases would be provided for by a sick club or in a provident hospital, but in Ireland no such institutions exist, and surely it would not be wise to put such patients to the alternative of remaining at home uncared for, or entering the union in association with the destitute.

But if the action of the enemies of the county infirmary were to succeed, the financial result to the taxpayer would be all the worse, for the majority of the patients who are now maintained by means of private subscriptions in the infirmary must needs become chargeable on the union funds, and a loss instead of a gain would accrue to the taxpayer.

We hope to see the question of maintenance of Irish County Infirmaries influenced by other considerations than those of politics, and that they will be dealt with by the cesspayer on their merits as public institutions. No one has so great an interest in sustaining them as the poorer cesspayers, and we hope they are not so unmindful of the interests of their class as to destroy the institutions which have for nearly a century done them such good service.

THE POOR-LAW SUPERANNUATION BILL.

THE Irish Poor-law Superannuation Bill will be reintroduced by Mr. Herbert Gladstone to-morrow, amended as recommended by the Select Committee of last year. It will probably not be in print for some days afterwards, but we shall inform our readers respecting it, if possible, next week.

THE TENURE OF OFFICE OF IRISH POOR-LAW
MEDICAL OFFICERS.

THE following important communication, to which we hope to refer at greater length in our next issue, has been made by the Council of the Irish Medical Association to the Irish Local Government Board :—

Irish Medical Association,
Royal College of Surgeons,
8th March, 1883.

To the Secretary,
Local Government Board for Ireland.

SIR,—The attention of the Council of the Irish Medical Association has been directed to the terms of Articles 36, 39, and 40, of the order of the Local Government Board ("General Regulations for the Administration of Workhouses"), dated December 18th, 1882, which has been recently issued by your Board, in substitution for Articles 38, 41, and 42 of the order of January 19th, 1852.

The Council observe that additions have been made to the original regulations, such as to authorise boards of guardians throughout Ireland, not only "at their discretion," to suspend union officers from the performance of their duties, and to deprive them of their salaries during the period of such suspension, but also to dismiss them from office, if the Local Government Board does not see fit to remove such suspension; while the order does not appear to contain any provision requiring boards of guardians to state their reasons for thus exercising their "discretion," or to institute any inquiry into the truth of charges which may have been made against the officer.

The Council, having already—in a recent correspondence with the Local Government Board respecting the removal of Dr. O'Reilly from his appointment as medical officer of the Lismore Workhouse—expressed their opinion as to the great injustice and inexpediency of submitting the tenure of office of the workhouse surgeon to the "discretion" of the guardians, subject only to a nominal control by the Local Government Board, refrain now from repeating the arguments and opinion then expressed. The Council, however, feel it necessary to state their unqualified belief that the dependence of the medical officer's tenure of office upon the caprice of the board of guardians must render impossible the conscientious and efficient discharge of that officer's duties, and certainly cause the permanency of his appointment to be largely influenced by personal or political considerations altogether apart from his competency or efficiency for his duties.

The Council, being of opinion that it never was the intention of Parliament that union officers should be dependent to this extent upon the goodwill of the majority of the board of guardians, have carefully examined into the law (1 and 2 Vic., cap. 56, sections 31 and 33) governing the appointment and dismissal of union officers, and are satisfied that the authority to remove a union medical officer, and the responsibility arising out of such an act, rest upon the Local Government Board alone, and that a dismissal or suspension by any other body whatsoever is wholly illegal and inoperative. The Council consider that any rule made for the purpose of transferring that responsibility to others altogether *ultra vires*. In this

view the Council are sustained by the opinion of Mr. Purcell, Q.C., on the points raised, and I am directed to forward herewith, for the perusal of your board, a copy of the case submitted to counsel, and his opinion thereon. I am further instructed to request that the Local Government Board, having taken such steps as they may consider expedient to confirm Mr. Purcell's opinion, may see fit to cancel their order referred to, and issue an amended one, which shall be in strict compliance with the provisions of the law on this subject, in order to give effect to the obvious intention of Parliament.

I am, Sir,
Your obedient servant,
W. THOMSON, F.R.C.S.I.,
Hon. Sec. to the Council.

[COPY.]

Re Irish Medical Association,
Opinion of THEOBALD PURCELL, Q.C.

1. Counsel will therefore please advise whether the Local Government Board can legally, by sealed order or otherwise, empower a board of guardians to dismiss or suspend the medical officer of the union under any circumstances whatever.

I am of opinion that the Local Government Board have no power to delegate to boards of guardians any authority to dismiss or suspend the medical officer of the union, and that the general orders to this effect in the Articles 39 and 40 of their recent Circular are *ultra vires* and illegal.

2. Should Counsel be of opinion that the Local Government Board (though not being able to delegate their power of dismissal) can legally delegate the power of suspending a union medical officer, can a board of guardians exercise such power of suspension in such a way as to practically dismiss the union medical officer? And Counsel's general opinion is requested.

I find no provision in any of the Acts in relation to the power of *suspension*. In my opinion, neither the Local Government Board nor a board of guardians have power to suspend a union medical officer, or to deprive him of his salary, except from the date of his dismissal by the Local Government Board, and that the provision in Article 36 of the recent Circular as to the deprivation of the medical officer's salary from the date of suspension is also *ultra vires*.

T. A. PURCELL.

71 Harcourt Street, Dublin,
15th February, 1883.

[COPY.]

No. 8,835—1883—Miscellaneous.
Local Government Board, Dublin,
March 10th, 1883.

SIR,—I am directed by the Local Government Board for Ireland to acknowledge the receipt of your letter of the 8th inst., with enclosure; and I am to acquaint you that your communication will receive consideration.

I am, Sir, your obedient servant,
W. D. WODSWORTH, Secretary.

W. Thomson, Esq., M.D.,
Stephen's Green.

the police, and with the authority of a magistrate, and, even in such case, no fee unless upon the order of the magistrate before whom the lunatic was brought. An order issued by the magistrate must be honoured by the guardians, and they can neither refuse payment nor reduce the amount. —Ed.]

CARLOW UNION.

A COMPLAINT.

DR. O'CALLAGHAN, of Bagenalstown, appeared before the board to complain of the refusal of Relieving Officer Lewis to pay a nurse employed in an urgent case. Dr. O'Callaghan stated that he was called on to attend a woman in her confinement. Her husband came home drunk and pulled her out of the bed, thus endangering her life. When he came again he found it necessary to get a woman to stay with her, and he got the man arrested. Subsequently he sent a note to the Relieving Officer to pay the woman what he considered proper. In reply the Relieving Officer sent an impertinent message to let the doctor who engaged the woman pay her.

The Relieving Officer said he received a note from Dr. O'Callaghan: "Please to pay Catherine Dowling for nursing two nights by my directions, and explain why she was not paid before."

Chairman—Had you got a message to pay before?

Relieving Officer—No.

Chairman—What reply did you send to this?

Relieving Officer—"If the doctor employed you let him pay you." I had no authority to pay anything except by the authority of the board.

Dr. O'Callaghan—It was simply a matter of life and death. The answer I got, and which I complain of, was an answer to the first note I sent to pay her what he thought fair.

Chairman—Here is a requisition from the medical officer to pay a nurse, and the question is did you refuse?

Relieving Officer—I had no authority.

Chairman—Suppose you got a message from the doctor to employ a nurse?

Relieving Officer—I would employ a nurse.

Chairman—You would have paid the nurse employed by yourself, and you would not pay the nurse employed by the doctor?

Relieving Officer—No. It is entirely against the rule.

Chairman—Not even in an urgent case?

Relieving Officer—No.

Relieving Officer Codd—The doctor has no power to employ a nurse without acquainting the relieving officer. If he does appoint a nurse he writes to the relieving officer at the earliest moment, and the relieving officer complies with it.

Mr. Fitzmaurice—I think in this case Mr. Lewis was entirely mistaken.

Chairman—I think so too. The board are surprised that Mr. Lewis should not have complied with the doctor's request, instead of relying on the red-tapeism of the law. You knew it was an urgent case, and in any case you should not have sent back an impertinent reply. The board has expressed its opinion, and no doubt in future Mr. Lewis will take care to conduct himself in a proper way, and not send impertinent messages.

HOUSES FOR WORKHOUSE MEDICAL OFFICERS.

THE following reply has been communicated by the Irish Local Government Board to an application from

the Guardians of the Gorey Union for a loan of money under the Dispensary Houses Act:—

Local Government Board, 22nd May.

SIR,—The Local Government Board for Ireland have had before them the minutes of proceedings of the Board of Guardians of the Gorey Union of the 6th inst., containing a minute of the guardians inquiring whether they can borrow money under the Dispensary Houses (Ireland) Act for the purpose of building a residence for the medical officer of the workhouse, and in reply the Board desire to state that the Act in question provides for the erection of a house or building to be used as a dispensary, or as a dispensary residence for the dispensary district in which such house or building is situate, and in section 2 of the Act the meaning of the expression "dispensary" is defined to be a dispensary house for the medical officer of any dispensary district appointed under the Medical Charities Acts. The Board do not think, therefore, that the provisions of the Act apply to the case of a medical officer of a workhouse who is not also a medical officer of a dispensary district.

IRISH MEDICAL ASSOCIATION.

ANNUAL GENERAL MEETING, 4TH JUNE, 1883.

Report of Council for the Year ending 31st May, 1883.

MR. PRESIDENT AND GENTLEMEN,—

During the year just terminated, your Council held four, and the Committee of Council forty-seven meetings.

INCORPORATION OF THE ASSOCIATION.

Your Council have to report that the steps necessary to have the Irish Medical Association incorporated have been completed during the past year, and that it now enjoys the status, duties, and privileges of an incorporated society. A special report on the subject of incorporation, containing the "Articles of Association," and "Memorandum of Agreement," was circulated amongst the members on the 23rd January last. Your Council, therefore, consider it unnecessary to report further on the subject.

THE MEDICAL REFORM BILL.

Upon the presentation of the Medical Acts Amendment Bill to the House of Lords by Lord Carlingford, in last March, the attention of your Council were most anxiously directed to it, and its provisions were carefully discussed. It was found that the Bill provided effectually for the objects which the Association has advocated through many years past, *i.e.*, (a) admission to the practice of the profession through one central examining body for each division of the Kingdom; (b) reconstitution of the General Medical Council, with direct representation of the profession thereon; (c) increased stringency of the law for the repression of illegitimate practice; the Council, therefore welcomed the measure as a legislative embodiment of the principles which have long been adopted by medical reformers, and presented to the Lord President of the Privy Council a memorial in favour of legislation on these principles, which memorial will be found in the appendix.

Nevertheless the Bill seemed to your Council to be defective in many of its details, especially in not providing for strict uniformity of education, examination, and examination fee in the three divisions of the Kingdom, in not distributing equitably the funds arising from examination and registration fees, and in not giving to the direct representatives their proper influence and status in the Medical Boards throughout the Kingdom.

Being most anxious to obtain such amendments of the Bill as would meet the threatened opposition of Irish

licensing authorities, the Council requested Dr. Jacob to proceed to London for the purpose of offering to Lord Carlingford the suggestions of the Association as to amendments of the measure. A petition in favour of the Bill, which will be found in the appendix to this report, was entrusted to Dr. Jacob for presentation to the House of Lords, provided the amendments sought for by the Association were conceded. Dr. Jacob had several interviews with the representatives of the Government on these subjects, and having received satisfactory assurances that the clauses which provide for uniformity of system throughout the Kingdom, and for distribution of the surplus funds, would be altered to a more acceptable form, he placed the petition in the hands of Lord Carlingford, who presented it to the House.

When the Bill reached the Committee stage, in April, it was found that the views of the Association on these points had been met by new clauses which, if not identical, are, at least, in the direction of the views adopted by the Association. At that stage a change of which the Association could not approve was made, in that the King's and Queen's College of Physicians was left with an insufficient representation on the Medical Board for Ireland; moreover, at the Board the direct representative had no seat, and, therefore, no direct influence in the important questions which are placed in the hands of the Board for settlement. In these and other minor respects the Bill is still open to improvement, and the Council has not relaxed its efforts to obtain further changes which, if adopted, will bring the Bill into complete conformity with the policy of the Association.

Having passed the House of Lords, the measure has been brought to the House of Commons, and read a first time, being in the hands of Mr. Mundella, Vice-President of the Privy Council. The order for its second reading occupies a place on the notice paper from day to day. At the Committee stage, which will probably not take place for a fortnight after the second reading, numerous amendments will be moved on behalf of the various licensing bodies, and your Council proposes, while giving the measure its warmest support, to take the opportunity to press for such changes as are necessary to make the measure perfect in the interest of the public and the medical profession generally.

UNION OFFICERS' SUPERANNUATION (IRELAND) BILL.

The Union Officers' Superannuation (Ireland) Bill of last year was read a second time in the House of Commons, on the 22nd of July, and sent to a Select Committee, empowered to send for persons, papers, and records. The Select Committee met 8th August, when Mr. Herbert Gladstone, M.P., who has charge of the Bill, was elected chairman.

After examination of several witnesses, including Dr. A. H. Jacob, on behalf of this Association, the Select Committee made a special and an ordinary report to the House, bearing date, 11th August, 1882, but nothing further could then be done towards passing the Bill, as the Session had almost expired.

A copy of each of those reports, and a forecast of this year's Bill, containing the amendments suggested, were circulated in the report of Council issued on the 17th October, which was sent to every member of this Association.

The new Bill, however, was not re-introduced until the 5th April last, notwithstanding that the Council pressed Mr. H. Gladstone to bring it forward at the opening of this Session. It now stands for second reading; but, in the present state of public business in the House, and as the Bill has been "blocked" by Mr. Biggar, it is impossible to say when the second reading will take place.

The terms of the Bill are identical with those of its forecast already referred to, but your Council understand that Mr. H. Gladstone is considering the advisability of inserting some alterations which, he says, will tend to

strengthen the position of the union officers. These alterations have not yet been communicated to your Council, but it is understood that Clause 4 will be omitted.

Your Council have made every effort in their power to have the Bill pressed forward without delay, fearing that if it be withheld until the approach of the end of the Session it may be abandoned. They are, however, assured that Mr. Herbert Gladstone is thoroughly in earnest and most anxious to have the Bill passed as soon as possible.

Your Council, in co-operation with the Union Officers' Association, sent delegates to London with a view to dissuade the objecting members from continuing to offer opposition to the Bill, and their exertions appear to have had good effect with all but Mr. Biggar, though it is understood that several amendments will be sought to be introduced, which, so far as they are known to the Council, need not be objected to on behalf of this Association.

In the reports of the Committee of Council, bearing date 17th October and 23rd January last, which were at the time issued to the members of the Association, very full information was contained relative to the Bill, and the steps taken in support of it. Your Council, therefore, feel it will not be considered necessary at present to make further reference to that measure beyond expressing a fervent hope that it may soon be passed. The Council earnestly solicit the co-operation of all the members of the Association in the effort to influence their Parliamentary representatives in favour of the measure, and they suggest that that influence would be best obtained by a personal letter.

NOTIFICATION OF INFECTIOUS DISEASES BILL.

On the 21st February last Mr. Hastings, M.P., re-introduced his Bill dealing with the notification of infectious diseases in England, and your Council at once requested Mr. Meldon, M.P., to re-introduce the Bill on the same subject, which was drawn up and agreed to by this Association in conjunction with the Dublin branch of the British Medical Association, in order that both Bills might be before the House at the same time. Mr. Meldon is only awaiting a favourable opportunity to re-introduce the Bill, the principles of which have been approved of also by the College of Physicians and the Royal College of Surgeons.

Your Council would remind the Association that the principle of this Bill is to make notification of infectious diseases to the sanitary authorities in Ireland obligatory on the householder or guardian of the patient, the medical attendant being at liberty to notify if he voluntarily undertakes that responsibility, and thereby binds himself under penalty to perform it, but not otherwise.

In practice your Council believe such cases will, almost without exception, be voluntarily reported by the medical attendant at the request of the householder, and thus the occurrence of cases of infectious disease will be more generally notified to the sanitary authority than under any other system which your Council is aware of.

MEDICAL WITNESSES AT INQUESTS.

A complaint was made to your Council by a member of the Association, to the effect that the Coroner for his district had recently held an inquest within a very short distance of the complainant's residence, and had brought with him, as medical witness, a gentleman who resides about nine miles from the place where the inquest was held, and who is not practising in the immediate neighbourhood.

This procedure on the part of the Coroner being illegal, inasmuch as the 33rd section of the Coroners' (Ireland) Act, 9 and 10 Vic, cap 37, provides that the Coroner shall summon, as medical witness, "any legally qualified medical practitioner being at the time in actual practice at or near the place where such death happened," your Council instructed Mr. Lloyd, Solicitor to the Association, to oppose the presentment for the fee; and when the case came before the Grand Jury, the Coroner was recommended in future to comply strictly with the law.

IRISH POOR-LAW INTELLIGENCE.

THE TENURE OF OFFICE OF IRISH POOR-LAW MEDICAL OFFICERS.

THE Irish Local Government Board is at present engaged upon one of those bureaucratic attempts to override the law and the rights of its officers, of which public departments are frequently guilty, when they hope that the proceeding will pass unnoticed, or that the victims will be unable to contend against illegal and oppressive regulations. It will be in the recollection of our readers that the Board recently encouraged a Board of Guardians to deprive of office a workhouse surgeon who had served for thirteen years without any challenge of his efficiency, and whom the Local Government Board itself declared to have merited no such treatment; and they did this act to conciliate the caprice of influential guardians, and to save themselves the responsibility and trouble of a contest on behalf of their own officer. This may appear to be a rash accusation against a public department, but we make it with, as we believe, a full knowledge of the circumstances, and with the conviction that proceedings and motives of the Irish Local Government Board cannot be truthfully expressed in other terms. The warning which we now give to Irish Poor-law medical officers is that the Board is seeking to make the injustice and illegality thus perpetrated towards a single officer a precedent for treating all officers in the same way, and placing them at the feet of the guardians throughout Ireland to be dealt with as the political, religious, or personal tastes of these officials may dictate; and the Local Government Board has already issued a general order under the signature of the Lord Lieutenant, the effect of which is to place all medical officers in this position.

On the 18th of December, 1882, a new general order for the administration of unions was promulgated, which superseded all former orders, and contained the following clauses:—

ARTICLE 40.—The Board of Guardians may, at their discretion, suspend from the discharge of his duties any union officer, except the clerk, chaplain, or treasurer, and shall forthwith report such suspension, together with the cause thereof, to the Local Government Board; and if the Local Government Board shall remove such suspension, such officer shall remain and continue to discharge his duties; but if the Local Government Board shall decide not to remove such suspension, the Board of Guardians may, on being informed of such decision of the Local Government Board, dismiss such officer.

ARTICLE 36.—The salary of every Officer or Assistant appointed to or holding any Office or employment under this Order, shall, subject to the regulations in Article 34, and to the obligation to account to the Auditor, be payable up to the day on which he ceases to hold such office or employment, and no longer; but no officer having been suspended by the Board of Guardians, in pursuance of Article 40, and who shall without the previous removal of such suspension be dismissed by the Local Government Board, or by the Board of Guardians, shall be entitled to any salary from the date of such suspension.

The words which we have italicised are those interpolated in both clauses to enable the Local Government Board to shift the responsibility of dismissal on the boards of guardians. We shall not lose time at present in discussing the unwisdom and the injustice of thus placing the union officer under the foot of the guardian, because the course which the board pursued toward Dr. O'Reilly, of Lismore, has sufficiently proved that this act of the board is influenced not by any sense of its unwisdom or injustice, but by an imperative desire to save itself trouble and responsibility. We do not, therefore, appeal to the Board to act towards their officers as is manifestly right, but we demand that they shall act legally and at least consistently with their own precedents and their own rules, and we regret that the conduct of this public department obliges us to say that it appears insensible to any influence, save a fear of Parliament and of the law courts, and that no redress can be expected from it except by calling into action those powers which are competent to restrain it.

These new rules promulgated by the board are in fact totally illegal and *ultra vires*. The Board has no more power to make them than to dictate orders to the Lord Chancellor, and if it acts under legal advice of any value at all, it must have been told that the Act of Parliament distinctly invalidates any or every attempt to shift the responsibility of dismissal of its officers to any person or body whatever.

There is but one Act of Parliament (the Irish Poor Relief Act of '38) which governs the matter, and the meaning of its provisions do not seem to us to admit of doubt. The 31st section of the Act runs as follows:—

“It shall be lawful for the Commissioners as and where they shall see fit, by their order, to direct the guardians of any union . . . to appoint such paid officers as the Commissioners shall think necessary . . . and the Commissioners may and they are hereby empowered to define, specify, and

direct the execution of the respective duties of such officers, and the places or limits within which the same shall be performed, and direct the mode of the appointment and determine the continuance in office or the dismissal of such officers and the amount and nature of the security, &c. . ."

It will be noted that under this section the Commissioners are to "direct the mode of appointment" (as, for instance, the method of convening the election meeting, the persons entitled to vote, and so forth), and they—and no one else—are to "determine the continuance in office or the dismissal of such officers." These words of themselves might be considered sufficiently explicit, but they are confirmed by the phraseology of the 33rd section, and by the Order originally made by the Commissioners themselves, and now, with singular inconsistency, reiterated. The 33rd section says:—

"The Commissioners may and they are hereby authorised and empowered as and when they shall think proper by their order, either upon or without any suggestion or complaint on that behalf from the guardians of any union to remove any paid officer appointed under the provisions of this Act whom they shall deem unfit for or incompetent to discharge the duties of any such office, or who shall at any time refuse or neglect to obey and carry into effect any of the orders of the Commissioners, and, in case of the refusal or neglect of the persons competent to appoint, the Commissioners are hereby authorised to appoint, &c."

It is here set down—one would think—sufficiently clearly that the Commissioners are the persons to dismiss and that the guardians have no power in the matter save to offer "suggestion or complaint" which the Commissioners may or may not give effect to; and it is to be noted that the officer is liable to dismissal only upon incompetency or unfitness, or for refusal to obey the orders of the Commissioners—it being clearly the intent of Parliament that the officer should not be open to removal because of declining to fulfil the guardians' orders, or to conform to their personal caprice, and that he should be to that extent, independent of them in the discharge of his duties.

Neither in this clause, nor in any other part of any Act of Parliament that we can find, is there any power whatever given to the Commissioners to delegate dismissal powers to any person or body; and, indeed, such delegation is contrary to the whole spirit of Irish Poor-law legislation. The Commissioners themselves interpreted the law in this sense, for, acting upon the authority of the law which we have quoted, they made the following rule:—

ARTICLE 39.—Every officer appointed to or holding any office under this Order shall, subject to the provisions of Article 40 of this Order, continue to hold the same until he die, or resign, or be removed by the Local Government Board, and every porter or assistant may be dismissed by the Board of Guardians without the consent of the Local Government Board; and every such death or resignation, and every such dismissal, and the grounds thereof, shall be reported to the Local Government Board.

It will be noted that herein a marked distinction is drawn between those menial servants which the guardians might dismiss, and those higher officers which the Local Government Board alone was entitled to deal with; and nothing can be clearer than that that Board, and they alone, have power to remove the higher officers. This rule has been transferred unchanged from the old rules to the new, and its presence in the Order of December 18, 1882,

serves to illustrate the slovenly way in which such documents are drawn up in the offices of the department, and how little confidence may be placed in the legal advice under which the Board acts. Here we find the Board stating that "every officer shall continue to hold office until he die, or resign, or be removed by the Local Government Board," while the very next rule (which we have already quoted) says that the same officer may be dismissed by a third party.

The view of the law of tenure of office which we have here explained is that taken by the Irish Medical Association in its correspondence with the Local Government Board which we published in our supplement last week; and that view is supported by the highest authority. The Association has not ventured to move until it took the best advice; and it has received the following replies to its queries from Mr. Purcell, Q.C., Chairman of Quarter Sessions for the County Limerick:—

1. Counsel will therefore please advise whether the Local Government Board can legally, by sealed order or otherwise, empower a board of guardians to dismiss or suspend the medical officer of the union under any circumstances whatever.

I am of opinion that the Local Government Board have no power to delegate to boards of guardians any authority to dismiss or suspend the medical officer of the union, and that the general orders to this effect in the Articles 39 and 40 of their recent Circular are *ultra vires* and illegal.

2. Should Counsel be of opinion that the Local Government Board (though not being able to delegate their power of dismissal) can legally delegate the power of suspending a union medical officer, can a board of guardians exercise such power of suspension in such a way as to practically dismiss the union medical officer? And Counsel's general opinion is requested.

I find no provision in any of the Acts in relation to the power of suspension. In my opinion, neither the Local Government Board nor a board of guardians have power to suspend a union medical officer, or to deprive him of his salary, except from the date of his dismissal by the Local Government Board, and that the provision in Article 36 of the recent Circular as to the deprivation of the medical officer's salary from the date of suspension is also *ultra vires*.

T. A. PURCELL.

71 Harcourt Street, Dublin,
15th February, 1883.

The reply of the Irish Local Government Board to the representatives of the Irish Medical Association, which we publish to day, is characteristic. It pleads that "the only difference between the new and former orders consists in boards of guardians having now authority to dismiss an officer whose suspension the Local Government Board does not see fit to remove." In this view of the new law we entirely agree; but we think that this little "only" clause makes a wonderful difference to the medical officer. It places him at the disposition of a class of persons who, we know by experience, will sacrifice him and his family without mercy if it pleases their religious or political prejudices to do so; it subjects him to endless annoyance at the hands of people whom he dare not offend, for if he does so, he may, at any time be thrown on the world without employment; it makes the

honest discharge of his duty impossible, because he cannot afford to tread upon the toes of influential people to whom the Local Government Board has handed the whip for chastisement.

We say advisedly that the new rules have all this pernicious effect, and we say so because we do not consider the protective control reserved to the Local Government Board of any value whatever to the officer. We have only to turn back to the Lismore case, and to many other instances in which the Board has deserted its well-deserving officers in their extremity, to verify the belief that the Board has not the firmness to face a contest with any board of guardians which desires to immolate an officer, or to meet the mildest popular clamour. The Commissions have lately hinted that it is not their business to interfere with the discretion of guardians, and that officers had better take care of themselves if they do not want to be dismissed; and we, therefore, emphatically reject the invitation extended to Irish Poor-law Medical Officers to put their trust in the department under which they act.

The Board has been referred to the sections of the Act of Parliament, as above quoted, and it seeks refuge in the third section of the same Act, which says that—

“The Commissioners are authorised and required from time to time, as they shall see occasion, to make and issue all such orders for the government of workhouses . . . and the poor therein, and for the guidance and control, appointment and removal of the officers thereof, and for guidance and control, according to the intentions of this Act, of all guardians, wardens, and other officers, paid or unpaid, acting on the management or relief of the destitute poor; and the Commissioners may, at their discretion, from time to time suspend, alter, or rescind such orders, or any of them.”

The Board expresses the opinion that this section gives them power to “authorise Boards of Guardians to dismiss certain officers described in the general order,” in which view not only we, but the much higher legal authority of Mr. Purcell, Q.C., entirely disagree. The Board may, under this clause, make any rules it pleases, “according to the intentions of the Act;” but it has no power to make any decree which goes in the smallest tittle against or beyond the words of the law. We do not suppose that the Board would pretend to any right to make a rule which would entitle the guardians to appoint or depose an auditor, or which would authorise the Commissioners to appoint the chairman of the guardians. Every one knows that every Act of administrative law contains a clause enabling the central authority to make rules “according to the intentions” of the law, and every one knows that such clause does not confer upon the central authority any power whatever to depart from the intention of the law under which it acts. The plea thus urged by the Irish Local Government Board is puerile, and we believe it would not stand five minutes before a court of law, and we hope that the Board will see the wisdom of taking better legal advice than that on which it has acted, and—if advised that its rules are *ultra vires*—rescinding them with as good grace as possible. If the Board does not adopt this course, it may reasonably assume that the first case of dismissal by a board of guardians will involve both the guardians and the

Commissioners in a lawsuit and a judicial decision which will not profit the guardians or do credit to the legal acumen of the law adviser of the Irish Local Government Board.

IRISH MEDICAL ASSOCIATION.

REPORT OF THE PROCEEDINGS OF THE COMMITTEE OF COUNCIL,

Read and adopted at a Meeting of the Council, held January 23rd, 1883.

Dr. WHISTLER, of Bray (Vice-President for Leinster), in the Chair.

(Concluded.)

RECOVERY OF FEES ON CANCELLED RED TICKET.

A dispensary medical officer, having been called upon, under the authority of a visiting ticket, to attend a patient whom he considered well able to afford to pay fees, brought the circumstances of the case under the notice of his dispensary committee, who thereupon cancelled the ticket.

The medical officer then sued the patient at Petty Sessions for £1 1s., the amount of his fee, and the justices asked the opinion of the law adviser, who recommended that they should dismiss the case, which they accordingly did. The Committee of Council then took up the case, which was listed for hearing at next Quarter Sessions, and directed that, if it were found necessary, a well-instructed junior counsel, nominated by the Committee of Council, should be specially retained, at the expense of the Association, to plead; and that if the case were unsuccessful, an appeal should be made to have the case tried in the Queen's Bench Division, as the Committee of Council deem it extremely important that the right to recover fees by a dispensary medical officer, upon whom such imposture has been practised, should be, once for all, established by the Supreme Court upon the first opportunity, in order that this form of abuse of the medical charities system may as effectively as possible be prevented.

There are very numerous instances in the Association's records, to which reference can at any time be made, in which claims of this nature have been allowed at sessions and assize courts, and the Committee of Council are not cognizant of any instance of late years in which such claims have been refused. It was therefore believed that the legality of such claims was fully established. However, should occasion arise for contesting the point in the Supreme Court, the Committee of Council are firmly of opinion that such course should be adopted in a spirited manner.

The Committee of Council have just learned, through Mr. Clifford Lloyd, Solicitor to the Association, that the difficulty in the case in question has just been removed by the claim having been settled out of court, the defendant having paid the fee demanded and a portion of the costs, as recommended for acceptance by the local solicitor.

In another instance of a similar nature, occurring in another county, a claim of £2 2s., for professional attendance given on a visiting ticket, which subsequently had been cancelled, was paid before the case came into court—a not unusual result. This case was also taken up by the Committee of Council.

The Committee of Council are advised that cases of this kind should not be brought into Petty Sessions Courts, as there is no appeal from such Courts beyond Quarter Sessions; and that it is advisable that such claims should, in the first instance, be heard at Quarter Sessions or Assize Courts, where, in the event of an adverse decision, it would enable the case to be brought

on appeal before the Supreme Court, where it would have a thorough hearing.

Any member of the Association feeling aggrieved in consequence of being called on, under the Dispensary system, to attend a case for which he undoubtedly ought to be paid for his services as a private practitioner, should immediately get the ticket cancelled by the Dispensary Committee, and then, if desirous of recovering his fees, forthwith communicate all the particulars of the case to the Hon. Secretary of this Association before initiating legal proceedings on his own account.

The Committee of Council understand that it is their duty to take up all such cases of unquestionable merit, and to have them conducted to their final issue at the expense of the Association, provided the case be managed strictly in accordance with their instructions.

NEW MEMBERS OF COUNCIL.

In compliance with the direction given at last meeting of Council, the Committee of Council have appointed Dr. Usher, of Dundrum, Co. Dublin, and Dr. Mackesy, of Waterford, to the two vacant seats in the Council, and they invited Dr. Austin Meldon, of Dublin, a member of Council, a compliment which he duly acknowledged with an expression of regret that his professional arrangements would prevent his being able to attend the meetings; consequently, the vacant seat in the Committee of Council has yet to be filled.

THE TENURE OF OFFICE OF WORKHOUSE OFFICIALS.

THE following communication in reference to the correspondence which we published last week has been received by the Irish Medical Association from the Local Government Board. The subject is fully dealt with in our issue of to-day:—

Local Government Board,
Dublin, March 22nd, 1883.

SIR,—The Local Government Board for Ireland have had under consideration your letter of the 8th inst., respecting terms of Articles 36, 39, and 40 of the Board's General Order of Dec. 18th, 1882, relating to the suspension of certain union officers from the discharge of their duties, and their dismissal from office, and in reference thereto the Board desires to call the attention of the Council of the Irish Medical Association to that part of Sec. 3 of Irish Poor Relief Act, 1838, which authorises the Board from time to time to make orders *inter alia* for the appointment and removal of workhouse officers. In pursuance of this enactment, general orders were made in the years 1839, 1844, and 1852, and in every one of those orders the guardians were given authority to dismiss certain officers, and, at their discretion, to suspend others from the discharge of their duties. No power in regard to the suspension of officers has been given to boards of guardians by the recent order in addition to what they possessed before, and the Local Government Board are unable to concur in the opinion which the Council appears to entertain that this order makes a medical officer's tenure of office dependent on the good will of the majority of the guardians, as the Board retains the power to remove the suspension, in which case the medical officer would remain and continue to discharge his duties. The only difference between the new and former orders consists in the board of guardians having now authority to dismiss an officer whose suspension the Local Government Board does not see fit to remove, and whose dismissal they approve of, and the Board are advised that they are fully warranted in making the regulation by the terms of the 3rd section of the Irish Poor Relief Act. The Local Government Board must dissent from the views of the Irish Medical

Association as to the construction and intention of the 33rd section of the Irish Poor Relief Act; that section enables the Local Government Board, if necessary, to act independently of a board of guardians, and to overrule their action in regard to the dismissal of an officer, but it does not deprive the Local Government Board of the power they possess under the 3rd section of the Irish Poor Relief Act to authorise boards of guardians to dismiss certain officers described in their General Order. The Local Government Board made the Order of 18th Dec., 1882, after very careful consideration and under legal advice, and they are not prepared at present to cancel their Order and to issue an amended one as requested.

I have the honour to be, Sir,
Your obedient servant,

W. D. WADSWORTH, Sec.

THE MEDICAL BILL.

THE following petition in favour of the Bill was presented last week by the Irish Medical Association:—

To the Right Honourable the Lords Spiritual and Temporal in Parliament assembled, the Petition of the President and Council of the Irish Medical Association

Most humbly sheweth—

That your Lordships' petitioners are the executive body of an incorporated Association, which numbers amongst its members more than one-third of the entire body of registered medical practitioners in Ireland, and which, for more than forty years, has been maintained in order "to unite the members of the medical profession in Ireland, and so form a body competent to exercise influence in sanitary and medical affairs for the public benefit, and to protect and promote the interests of the medical profession."

That your Lordships' petitioners have considered the provisions of the Medical Acts Amendment Bill, now standing for a second reading before your Right Honourable House, and fully approve of the principles of said Bill.

That the Irish Medical Association has, at many successive annual general meetings, declared its approval of the proposals—

a. To restrict the privilege of registration as a medical practitioner to persons who shall have passed before a Central Examining Board for each division of the Kingdom an examination adequate to ensure their competency, registration being granted throughout the Kingdom upon equal terms as regards standard of examination, duration of study, and amount of fees payable prior to examination.

b. To reconstitute the General Medical Council, so that an adequate direct representation therein of the registered medical practitioners throughout the Kingdom shall be secured.

c. To amend the existing law so as to check effectively the practice of medicine and the improper use of medical titles by unqualified persons.

That your Lordships' petitioners are aware great abuses have arisen in the granting of licences to practise medicine, and great injury has arisen to the public from the difficulty of distinguishing between competent and incompetent practitioners by reason of the inefficacy of the existing law.

That your Lordships' petitioners therefore humbly pray that your Most Honourable House will be pleased to pass said Bill.

(Signed)

JAMES MOLONY, President.

JOHN H. CHAPMAN, Hon. Sec.

IRISH POOR-LAW INTELLIGENCE.

POOR-LAW SUPERANNUATION (IRELAND) BILL.

THIS Bill stands for a second reading, and only waits for an occasion when the notice-paper of the Commons is clear enough to enable it to come on before midnight. After that hour it cannot, by the rules of the House, be taken, because the delectable member for Cavan, Mr. Biggar, and Mr. Richard Power, member for Waterford, have "blocked it"—i.e., given notice of a motion that it "be read a second time this day three months," which is the Parliamentary way of expressing rejection. Every effort has been unavailingly made to induce these gentlemen to take off the block, and therefore there is no way over the difficulty save for Mr. H. Gladstone to get the Bill put high up on the notice-paper, and fight it out with the Obstructives, who, we believe, are in a helpless minority. Unfortunately, this is not easily managed, and the Affirmation Bill has made it impossible for the present; but after Whitsuntide progress may be hoped for.

THE H. H. H. STEWART BEQUEST.

THE Master of the Rolls for Ireland—Sir Edward Sullivan—has recently given judgment as to the disposition of the estate left by the late Dr. Henry Hutchinson Stewart. Dr. Stewart occupied a remarkable position in the medical history of the last half century. He held the position of governor of the House of Industry, a sort of industrial institution which existed fifty years ago in Dublin, and which has since been converted into the House of Industry Hospital, by which name the Richmond (surgical), Whitworth (medical), and Hardwicke (fever) are now known. On the introduction of the Irish poor relief system, the House of Industry was abolished, and a number of the pauper lunatics were confided by Government to the care of Dr. Stewart, who maintained them at first at Island Bridge, near to Phoenix Park, and afterwards at Lucan, about six miles from Dublin. In this way, Dr. Stewart became the proprietor of a large asylum at Lucan, and amassed a considerable fortune, part of which has now been disposed of by the Master of the Rolls. Dr. Stewart's name will live in the memory of our profession as that of one of its most benevolent members. His first act after his retirement from active life was to hand over the valuable and spacious premises at Lucan, a free gift towards the foundation of the "Stewart" Institution for Imbeciles and

Lunatics, and at the same time he gave a large donation towards erecting a suitable building. After that time it was Dr. Stewart's habit to live in the most sparing manner, and to hand over to charity immediately the money thus saved by the sacrifice of his own pleasures. In this way he presented considerable sums from time to time to the Royal Medical Benevolent Fund Society in Ireland, and other charities, but his benevolence in this way did not prevent his leaving, after his death, a sum of about £18,000. Respecting this sum, he left only very indefinite instructions, and the Master of the Rolls was, therefore, called upon to dispose of the funds. To the Stewart Institution he gave a sum of about £2,000, sufficient to wipe off an old-standing debt due by the Institution to Dr. Stewart, and the balance he set aside for the endowment of medical scholarships in the University of Dublin and the Royal Irish University. We cannot but regret that the learned judge should have selected this method of disposing of Dr. Stewart's money. He might with great advantage have endowed the Irish Medical Benevolent Fund, with which for many years Dr. Stewart had been closely associated; or he might, if he considered himself restricted to medico-educational objects, have found many worthy purposes to which the money might have been given. The learned judge could hardly have found a purpose less consistent with the testator's wishes or with the interests of the public and the profession than those he has selected. Indeed, considering that the University of Dublin is wealthy enough to pay for any number of medical scholarships, and that the Royal Irish University is a State-supported institution, we can hardly imagine a less useful appropriation of Dr. Stewart's money than the handing it over to these institutions. If the benevolent testator could have known the object to which his savings would have been given, we are confident he would not have left a shilling of his money undistributed.

THE IRISH MEDICAL ASSOCIATION AND THE MEDICAL BILL.

THE following Memorial was presented last week to the Lord President of the Council by Dr. Jacob, on behalf of the Irish Medical Association:—

TO THE RIGHT HONOURABLE THE LORD PRESIDENT OF THE PRIVY COUNCIL.

The Memorial of the President and Council of the Irish Medical Association.

Humbly sheweth—

That your Lordship's memorialists having urged upon your Lordship the necessity for legislation for amendment of the Medical Acts, acknowledge with satisfaction and thankfulness the efforts of Government to promote such legislation, and have petitioned the House of Lords in support of the principles of the Medical Bill.

That your Lordship's memorialists nevertheless view with regret the proposal of the constitution of the Medical Board for Ireland contained in clause 9, subclause 5 of the amended Bill, inasmuch as it is therein proposed to exclude the directly elected representative of the medical practitioners of Ireland, and to give to the King's and Queen's College of Physicians only two representatives on the same Board.

That it is the opinion of your Lordship's memorialists it would be both unjust and inexpedient to exclude from consideration of Irish medical arrangements the representative of the medical practitioners in Ireland, and to limit the influence of that representative to the part which he may take in a meeting or meetings of the Medical Council for a few days in each year.

That without desiring to enter into a comparison of the respective claims of the medical authorities to be represented in said Board, your memorialists feel it their duty to give emphatic expression to the opinion that the licensing corporations of Ireland are by the extent of their work in medical education and qualification, by the high standard of curriculum and examination which they have maintained, and by the regard which they have shown for the general education and culture of their licentiates, fully entitled to an influence in the Medical Board equivalent to that secured to the Irish Universities by the Bill, and that the College of Physicians is in no respect deserving of less influence upon Irish medical affairs than any of the other medical authorities.

That your Lordship's memorialists consider the proposed method of election of the members of the Medical Board altogether objectionable, because in most instances it does not provide for the true representation of the constituents of the electing body, but vests the elective power in governing authorities which are frequently self-appointed, and are seldom so constituted as to be entitled to speak on behalf of the constituency. Your Lordship's memorialists are therefore strongly of opinion that clause 54, lines 29 to 32, page 30, ought to be so altered as to vest future power of election in the Fellows, Medical Graduates, or other medical corporate voters of the body entitled to return the delegate.

Your Lordship's memorialists therefore humbly pray that Her Majesty's Government will be pleased to give their support to the proposition for the amendment of the Bill in the direction above indicated.

Signed on behalf of the Irish Medical Association,

JAMES MOLONY, F.R.C.S.I., President.

JOHN H. CHAPMAN, F.K.Q.C.P.I., Hon. Sec.

LIST OF ENTRIES IN THE REGISTER OF THE
BRANCH MEDICAL COUNCIL (IRELAND) FOR
THE MONTHS OF FEBRUARY AND MARCH, 1883.

FEB. 1st.—Gowland, J. W.; Newton House, Rathgar; M.B. and Bac. Surg. Univ. Dub. 1882.

1st.—Martin, W. A. P.; Markethill, co. Armagh; M.D. R. Univ. Irel. 1882.

13th.—Alcorn, S. A.; New South Wales; M.B. and Bac. Surg. Univ. Dub. 1883.

14th.—Concannon, Austin; Tuam, co. Galway; Lic. R. Coll. Phys. & Surg. Edin. 1883; L.A.H. Dub. 1882.

14th.—Carry, W. W. S.; St. Mark's Hosp., Dublin; Lic. R. Coll. Surg. Irel. 1882; L.A.H. Dub. 1883.

14th.—Fetherstonhaugh, W.; 2 Belgrave Square West, Monkstown; Lic. R. Coll. Surg. Irel. 1879.

16th.—Curtis, J. H.; 7 Camden Place, Cork; Lic. R. Coll. Phys. & Surg. Edin. 1883.

16th.—Peet, F. F. Tralee; Lic. R. Coll. Surg. Irel. 1882.

17th.—Graham, S.; Legoniel, co. Antrim; Lic. R. Coll. Phys. Lond. 1883.

23rd.—Torney, G. P.; 8 Blackball Street, Dublin; Lic. R. Coll. Surg. Irel. 1882.

27th.—Finegan, J. P.; Kingscourt, co. Cavan; M.B. and Bac. Surg. Univ. Dub. 1883.

MARCH 1st.—Lane, Thomas; 127 Leinster Road, Dublin; Lic. R. Coll. Surg. Irel. 1882; Lic. K. Q. Coll. Phys. Irel. 1883; Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

7th.—Heffernan, Geo. B.; 22 Charleville Road, Rathmines, co. Dublin; Lic. R. Coll. Surg. Irel. 1882.

9th.—Hatch, Richard; Duleek, co. Meath; Lic. R. Coll. Surg. Irel. 1881; Lic. & Lic. Mid. K. Q. Coll. Phys. Irel. 1882.

13th.—Tweedy, William; Newry Street, Banbridge; Lic. R. Coll. Phys. & Surg. Edin. 1883.

13th.—O'Callaghan, J. Dromleigh; Macroom, Cork; Lic. R. Coll. Phys. & Surg. Edin. 1882.

20th.—Brooks, H. St. J.; 7 Chelmsford Road, Dublin; M.B. & Bac. Surg. Univ. Dub. 1882.

24th.—Garham, John; Clifden, co. Galway; Lic. R. Coll. Phys. & Surg. Edin. 1882.

28th.—Howard, Timothy; 9 Herbert Road, Sandymount; Lic. R. Coll. Surg. Irel. 1882; Lic. & Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

28th.—Gormley, J. W.; Peter St., Drogheda.

28th.—Cruise, F. J.; 93 Merrion Square West, Dublin; Lic. R. Coll. Surg. Irel. 1882.

UNION OFFICERS' SUPERANNUATION BILL.

Abstract of a Bill to make better provision for the Superannuation of the Officers of Poor-law Unions in Ireland.

Introduced April 5, 1883, by Mr. Herbert Gladstone, Mr. Trevelyan, and the Attorney-General for Ireland.

BE it enacted, &c.

1. This Act may be cited as the Union Officers' Superannuation (Ireland) Act, 1883.

2. *Grant of Superannuation.*—From and after the passing of this Act the board of guardians of every union in Ireland shall, with the sanction of the Local Government Board for Ireland (in this Act called "the Local Government Board"), grant to any union officer belonging to that union who shall become incapable of discharging the duties of his office with efficiency by reason of permanent infirmity of mind or body or of old age, upon his resigning or otherwise ceasing to hold his office, a superannuation allowance, according to the following scale—that is to say—

To any officer who shall have served in some one or more unions in Ireland for ten years and upwards, and under eleven years, an annual allowance of ten-sixtieths of the annual salary and emoluments of his office:

For eleven years and under twelve years, an annual allowance of eleven-sixtieths of such salary and emoluments:

And in like manner a further addition to the annual allowance of one-sixtieth of such annual salary and emoluments in respect of each additional year of such service until the completion of a period of service of forty years, when an annual allowance of forty-sixtieths shall be granted, and no addition shall be made in respect of any service beyond forty years.

No officer shall be entitled to such allowance on the ground of age who shall not have completed the full age of sixty years, and shall not have served as a union officer in some one or more unions in Ireland for twenty years at the least.

For the purposes of this section, the annual salary and emoluments of a union officer shall be calculated on the average of the three years ending with the quarter-day next before he ceases to hold his office.

No officer shall be entitled to any superannuation allowance or gratuity under this Act unless the Local Government Board are satisfied that he has discharged his duties as a union officer with diligence and fidelity.

3. *Allowance in Cases of Bodily Injury.*—The board of

guardians of any union, with the sanction of the Local Government Board, may, if they think fit, grant to any person, being the holder of a union office in the union in respect of which a superannuation allowance might be granted under this Act, who, before the completion of the period which would have entitled him to a superannuation allowance, is compelled to quit the service of the union by reason of severe bodily injury occasioned, without his own default, in the discharge of his duty as a union officer, a gratuity not exceeding three months' pay for every two years' service, or a superannuation allowance not exceeding ten-sixtieths of the annual salary and emoluments of his office; and may, if they think fit, with the like sanction, grant to any such holder of a union office who is compelled from infirmity of mind or body to leave the union service before the completion of the period which would have entitled him to a superannuation allowance, such sum of money as the board may think proper, but so that no such gratuity shall exceed the amount of one month's pay for each year of service.

4. *Local Government Board may Reduce any Pension.*—Whenever an application is made to the Local Government Board to sanction the grant to any union officer by a board of guardians of a superannuation allowance or gratuity under this Act, it shall be lawful for the Local Government Board either to sanction or to refuse to sanction such grant, or to sanction the grant of a superannuation allowance or gratuity to such officer of such less amount than otherwise would have been awarded to him as the Local Government Board may determine, where the defaults or demerit of such officer in relation to the union service appear to them to justify such diminution.

5. Every superannuation allowance or gratuity granted under this Act shall be payable to, or in trust for, the union officer, and shall not be assignable nor chargeable with his debts or other liabilities.

6. *Discontinuance of Pension in certain Cases.*—In case any person enjoying any superannuation allowance under this Act is appointed to be a union officer in any union, every such allowance shall cease to be paid so long as he continues to hold such appointment if the annual amount of the profits of the office to which he is appointed are equal to those of the office formerly held by him; and in case they are not equal to those of his former office, then no more of such superannuation allowance shall be paid him than with the salary of his new appointment shall be equal to that of his former office.

7. *Provision for Cases of Professional Qualification.*—The Local Government Board may from time to time, by order, declare that for the due and efficient discharge of the duties of any union office or class of offices to be specified in such order, professional or other peculiar qualifications are required, and that it is for the interest of the public that persons should be appointed thereto at an age exceeding that at which public service ordinarily begins; and may, by the same or any other order, direct that when any person holding any such office shall retire from the union service, a number of years not exceeding ten, to be specified in the order, shall, in computing the amount of the superannuation allowance which may be granted to him under this Act, be added to the number of years during which he may have actually served.

8. The Local Government Board may from time to time make rules with reference to the mode in which a union officer shall establish what his age is, and establish that he has discharged his duties with diligence and fidelity, and with respect to any other conditions the fulfilment of which the Board may require to be proved; and in the case of an officer retiring on the ground of infirmity of mind or body, if the Board by any such rules require the officer to appear for examination before a medical board, or before a medical practitioner nominated by the Local Government Board, the Local Government Board may defray the expenses of such examination out of the superannuation fund provided by this Act.

9. All allowances and gratuities payable under this Act shall be advanced from time to time by the board of guardians of the union in which the officer was serving at the time of his ceasing to be a union officer, and shall be repaid to the board of guardians out of the union officers' superannuation fund.

For the purpose of providing for such repayments, the following enactments shall take effect:—

(1.) On, or as soon as conveniently may be after, the first day of January in every year after the passing of this Act, the Local Government Board shall estimate what sum will be necessary for the purposes of this Act during the year.

In making the first of such estimates under this Act, the Local Government Board shall estimate what sum will be necessary for the purposes of this Act during the whole of the period between the passing of this Act and the first day of January next following the making of the estimate.

The Local Government Board shall in each year, by order under their seal, assess that sum on the several unions in proportion to the net annual value of the property therein. They shall send copies of the order to the guardians and to the treasurer of each union.

(2.) Thereupon the treasurer shall, if he has then in his hands to the credit of the guardians sufficient funds, pay the amount so assessed into the Bank of Ireland; and if he has in his hands to the credit of the guardians funds not sufficient for payment in full of the amount so assessed, he shall pay into the Bank of Ireland such balance as he may have in his hands in reduction of the amount so assessed; and in such case, or if he has no funds in his hands to the credit of the guardians, then he shall, out of all moneys subsequently received by him on account of the guardians, pay the amount assessed into the Bank of Ireland. Moneys paid into the Bank of Ireland under this Act shall be placed to the credit of a fund which shall be called the Union Officers' Superannuation Fund.

The guardians of each union shall debit the several electoral divisions with proportions of the sum assessed upon the union, according to the net annual value of the property in each division.

(3.) On the 25th day of March, 1884, and on every 29th day of September and 25th day of March following, the guardians of each union shall furnish to the Local Government Board accounts of the moneys expended by them for superannuation allowances and gratuities payable under this Act since the date of the last preceding account, or, in the case of the accounts furnished on the 25th day of March, 1884, since the date of the passing of this Act; and the Local Government Board shall pay to the treasurer of the union, out of the union officers' superannuation fund, the amount mentioned in the account furnished by the board of guardians of the union when such amount has been found to be correct.

10. In this Act the term "union officer" includes every person appointed by the board of guardians of any union to be a permanent officer of the union under the provisions of the 31st section of the Act of the session of Parliament of the 1st and 2nd years of the reign of Her present Majesty, chapter 56, and the 4th section of the Act of the session of Parliament of the 10th year of the reign of Her present Majesty, chapter 31, whether such officer is paid by wages, poundage, or percentage on collection of rates, or by a salary; and also every chaplain of a union, and every medical or surgical officer of a union, or of any dispensary district therein; and every person appointed or constituted as sanitary officer under the 11th section of the Public Health (Ireland) Act, 1878, or clerk to the burial board of any district where such burial board is a board of guardians, or clerk to the local authority acting in execution of the Contagious Diseases

Supplement of The Medical Press and Circular

(Animals) Act, 1878, where such person has been so appointed by a board of guardians, or holds his office as a sanitary officer, or clerk of the burial board, or clerk of the said local authority, by virtue of any other guardians; which he has been appointed by a board of guardians; and also the registrar of births, deaths, and marriages in every union, and the superintendent registrar, being also the clerk of the union.

The term "emoluments" includes all fees, poundage, and other payments made to a union officer for his own use, as such union officer out of poor rate or sanitary rate, or money voted by Parliament; and also the remuneration or money voted by Parliament; and other remuneration value of rations, apartments, and other remuneration appertaining to the office held by such union officer, estimated according to such scale or in such manner as the Local Government Board shall prescribe.

11. The Acts specified in the schedule to this Act are hereby repealed so far as they relate to the superannuation of any officer who retires from his office after the passing of this Act.

This repeal shall not affect the powers of the board of guardians of any union with reference to the granting of a superannuation allowance under any of the said Acts to an officer who has retired from his office before the passing of this Act; nor anything duly done or suffered, nor any right or liability acquired, accrued, or incurred, under any enactment hereby repealed; and shall not relieve the board of guardians of any union from the obligation to pay any superannuation allowance granted by them under any of the said Acts.

SCHEDULE (referred to in Section 11).

Session and Chapter.	Title or Short Title.
28 & 29 Vic., c. 26.	An Act to provide for superannuation allowances to officers of unions in Ireland.
32 & 33 Vic., c. 50.	The Medical Officers' Superannuation Act (Ireland), 1869.
35 & 36 Vic., c. 89.	An Act to amend the Act providing superannuation allowances to officers of unions in Ireland.

CORONERS' SALARIES.

At the recent Commission of Assize for Queen's County, Chief Justice Morris presiding in the Crown Court, the question of coroners' salaries was brought before his Lordship.

Dr. Higgins, the coroner for one of the divisions of the county, applied to the Grand Jury for a presentment for £52, half a year's salary, and £6 for three inquests held out of his division. Dr. Quirke, the coroner for the other division, also applied for £52, half a year's salary. It appears that upon the passing of the Act commuting the paying of coroners by fees to payment by salary, the coronerships for the county were held by the late Mr. Clarke and Dr. O'Kelly. The Act provides that the salary fixed shall be based on the amount of fees paid to the coroner or his predecessor for five years previous to the passing of the statute. About seven years before the passing of the Act, Dr. O'Kelly went to reside out of the county, and the Grand Jury found that they could not present for his fees under the circumstances. The consequence was that though Dr. O'Kelly had not resigned his appointment he did not hold any inquests during the five years previous to the passing of the Act, and the work of the entire county was consequently done by Mr. Clarke. A committee of the Grand Jury fixed Mr. Clarke's salary—upon the work of the entire county—at £104, and no salary was fixed for Dr. O'Kelly. Upon Mr. Clarke's death Dr. Higgins was elected coroner for the division held by the deceased gentleman, and claims the amount of salary Mr. Clarke received. Dr. O'Kelly held office for some short time after Mr. Clarke's death, still doing no

work. He subsequently resigned, and Dr. Quirke was elected to his division. Dr. Quirke also claims a salary of £104 a year. The Grand Jury threw out both presentments, in order that the question might be brought before the judge.

The question having been argued at some length, his Lordship said it appeared to him the Act of Parliament had been framed without a full knowledge of the subject, as this case exemplified. No provision was made for contingencies. He was only putting a reasonable interpretation upon the Act when he said that a "predecessor in office" was the person who previously held the post. Accordingly, Dr. Quirke was entitled to Dr. O'Kelly's salary, which was nil. The Grand Jury had passed a resolution of remonstrance on this subject at the last July assizes. The Act of Parliament was his master in the matter, and he must abide by it. He would therefore pass the presentment at £104 for Dr. Higgins.

ELECTION OF MEDICAL OFFICER FOR HEADFORD DISPENSARY DISTRICT

A MEETING of the Dispensary Committee for Headford district was recently held for the purpose of electing a medical officer in room of Dr. J. C. Flood, then resigned. The result was a tie, ten having voted for Dr. Charles J. Blake, of Tuam, and ten for Dr. James Gorham, of Letterfrack, the only candidates nominated. Mr. O. Flaherty there and then objected to the votes of two members of the committee, inasmuch as one had been adjudicated a bankrupt, and the other was not a rated occupier in the district; and on these grounds claimed the election for Dr. Blake. Dr. Gorham made a counter objection, representing the proceedings to have been illegal, one of the Poor-law guardians not having been notified to attend the election. All objections and protests for and against were forwarded to the Local Government Board, but that body not having determined the issue one way or the other, the committee recently appointed met on Tuesday when Dr. Blake and Dr. Gorham again entered the lists, and the former was returned by a majority of two. In appointing committee the week before last some changes were made.

* It being put to a poll, there voted for Dr. Blake, 12.

For Dr. Gorham, 10.

The chairman declared Dr. Blake duly elected.

Dr. Blake briefly returned thanks, whereupon the proceedings terminated.

EXTIRPATION OF THE COCCYX.

THIS operation was done by Marie B. Werner, M.D., Philadelphia, in the case of a married woman who came under her care for intolerable backache, which was always aggravated in the act of sitting down, or resuming the erect posture. On examination the extremity of the coccyx was found to be very painful, and turned to the right. The patient had suffered from this pain for a year and a-half, since her last confinement. It was determined in consultation that mere division of the ligaments would not suffice, so extirpation of the bone was resolved upon. The patient made a good recovery. There was a good deal of interference with the power of making water until the patient was able to be up and about again. Acute pain of a throbbing, stinging, and cutting character was felt on the third day, but this was relieved by the removal of the three stitches by which the wound was closed, and which had been introduced deeply to keep the parts well together. Some pain and soreness remained for six weeks after removal of the bone, but this gradually subsided. The free extremity of the bone was found to be the seat of commencing osteitis.

IRISH POOR-LAW INTELLIGENCE.

THE IRISH MEDICAL ASSOCIATION

HELD its Annual Meeting at the Irish College of Surgeons on Monday last.

The usual breakfast of the members took place at the Shelborne Hotel, the chair being occupied by Dr. Robert Browne, Chairman of the Council of the Association.

The Annual Meeting commenced at 11 a.m. at the College, Dr. Moloney, of Tulla, President of the Association, being in the chair. After the reading of the Report (which we print in our Irish Supplement of the present issue), the following resolutions, amongst others, were moved and adopted :—

“That the Medical Act (1858) Amendment Bill now before Parliament is approved in principle by this Association, and that the Council are hereby instructed to support said Bill, while endeavouring to obtain such amendments as appear to them desirable.”

“That the Union Officers' Superannuation (Ireland) Bill of this session is entitled to the warm support of this Association, and that the Council are hereby requested to exert all the influence of this Association, with a view to secure the passing of said Bill this session.”

“That Mr. Meldons' Notification of Infectious Diseases (Ireland) Bill deserves the support of this Association, and that the Council are hereby directed to oppose any Bill which proposes that the duty of notifying infectious diseases to the sanitary authorities shall be made obligatory upon the medical attendant.”

“That the present system of dispensary medical relief, under which a large proportion of tickets is indiscriminately issued, is opposed to the public interest, as it directly leads to habits of dependence and improvidence, and at the same time not only improperly increases the poor rates, but also unfairly occupies the time and services of the medical officers, who are thereby deprived of legitimate fees.”

In the evening the members of the Association met for dinner, under the Presidency of Dr. Jacob, who had been selected for the coming year. Amongst those present were the Presidents and Vice-Presidents of the Colleges of Physicians and Surgeons, the Principal Medical Officer of the Army Medical Department for Ireland, the Medical Commissioner of the Local Government Board, the Registrar-General, the President of the Academy of Medicine, and other distinguished guests.

We hope to give a fuller report of the day's proceedings in our next issue.

LIST OF ENTRIES IN THE REGISTER OF THE BRANCH MEDICAL COUNCIL (IRELAND) FOR THE MONTH OF APRIL, 1883.

APRIL 6th.—Crowe, Daniel; Blackrock, co. Dublin; M.B. Univ. Dub. 1882; Bac. Surg. Univ. Dub. 1883.

7th.—Currie, Robert; Ballymena, co. Antrim; Lic. R. Coll. Phys. & Surg. Edin. 1883.

7th.—Henry, James; Monaghan; M.D. R. Univ. Irel. 1882; Mast. Surg. R. Univ. Irel. 1882; Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

7th.—Hackett, J. C.; Dungarvan; M.D. and Mast. Surg. R. Univ. Irel. 1882.

9th.—Armstrong, John; 8 Leeson Park, Dublin; M.B. Univ. Dub. 1882; Bac. Surg. Univ. Dub. 1883.

13th.—Campbell, K. J.; 87 Stephen's Green, Dublin; Lic. R. Coll. Phys. & Surg. Edin. 1883.

14th.—Kennedy, D. W.; Castleshane, co. Monaghan; Lic. R. Coll. Surg. Irel. 1882.

14th.—Wright, W. A.; Anglesea, N. Wales; L.A.H. Dub. 1883.

16th.—Hoey, J. C.; 1 Royal Marine Road, Kingstown; Lic. R. Coll. Surg. Irel. 1882; Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

17th.—Hamilton, W. R.; Fivemiletown, co. Tyrone; M.D. R. Univ. Irel. 1882; Mast. Surg. R. Univ. Irel. 1882; Lic. Mid. K. Q. Coll. Phys. Irel. 1883.

18th.—Allen, J. T. W.; 52 Richmond Street, S. Dublin; L.A.H. Dub. 1883.

19th.—Fryer, W. F.; Clonburrin, Bagenalstown; Lic. R. Coll. Phys. and Surg. Edin. 1882.

PAYMENT OF DISPENSARY SUBSTITUTES.

KILMEAGUE DISPENSARY.

The following correspondence was read :—

“May 29th, 1883.

“DEAR SIR,—At a special meeting of the committee held on this day (Rev. J. Farrell, P.P., in the chair), the enclosed resolution and amendment, also medical certificate, were submitted. The medical officer expects the board of guardians will be good enough to pay his *locum tenens* during his absence on sick leave, as is usual in such cases, as he believes he is not bound to do so.

“I am, yours, &c.,

“J. M. NEALE, Hon. Sec.”

A certificate of ill-health signed by Dr. Wheeler, Surgeon to the City of Dublin Hospital, was enclosed.

Proposed and seconded :—“That Dr. Sale be granted one month's leave of absence, he paying a properly-qualified substitute.”

Proposed as an amendment :—“That a month's leave of absence be granted, and that the guardians pay for a substitute.”

Mr. Nolan said the committee were of opinion that Dr. Sale was quite able to pay for his own substitute.

The Clerk observed that in all his experience he never heard of the same thing occurring before. The board never refused to pay for a substitute up to this.

Mr. Dunne said it was also unusual to interfere with the proceedings of a dispensary committee.

Mr. Tracy considered it very hard lines that when a medical officer was incapacitated by ill-health the guardians should refuse to pay for a substitute.

Sir Erasmus Borrowes was likewise in favour of the recommendation of the dispensary committee.

It was decided that the resolution that the medical officer pay for a substitute be agreed to.

STROKESTOWN DISPENSARY.

Mr. Dick proposed the payment of a substitute for Dr. Shanley. He said Dr. Shanley was such an old officer of the board—having he believed over 31 years' service, that no apology is necessary for the step I have taken—an old and tried officer who has given the most unqualified satisfaction in the discharge of his duties, and who has at all times made himself conspicuous by his liberality and attention to the poor is deserving of any compliment and consideration this board may have in their power to bestow. It is usual that the substitutes of medical officers are paid by boards of guardians, and this board will not, I trust, take a step that may in any degree detract from its ancient principles, which have always been honest, just, and honourable.

Mr. Cox said with regard to the resolution proposed, he fully concurred, but he had his duty to perform to the ratepayers. Unfortunately, if that resolution was carried the salary will have to be paid out of the rates for the doctor's substitute, and is a further burden on the ratepayers. Under these circumstances he would propose that Dr. Shanley pay a substitute himself.

On its being put to a poll, there voted for the resolution, 5; for the amendment, 6.

The Chairman announced the amendment carried by a majority of one.

It ought to be unnecessary for us to remind Poor-law Medical Officers that, if they are foolish enough to pay their substitutes in illness, they have none but themselves to blame.

In the terms of the Regulations—the duty of a dispensary medical officer, in case of his being “temporarily incapacitated by illness of other cause,” is strictly confined—*first*, to his “immediately, if practicable, communicating with the chairman or honorary secretary,” and *secondly*, to “recommending” a duly qualified *locum tenens*. The medical officer is not authorised to appoint his substitute, and the committee have full discretion to act upon his recommendation, or to disregard it, as they see fit—he has not any authority whatsoever to make arrangements with the *locum tenens* as to his remuneration, nor would any promises made by him be in the least binding either on the committee or the board of guardians—he is simply directed to suggest to the committee the name of a medical man who possesses the qualifications required by the regulations, and in doing so he will, of course, act rightly in recommending a practitioner who can conveniently and effectually discharge the duties for the advantage of the sick poor.

The practitioner who acts as *locum tenens* should understand that it is incumbent on him, without a moment's delay to arrange with the secretary for his *ad interim* duties; but he should recollect that his acting for the medical officer is irregular until he has a definite appointment from the responsible officer of the dispensary committee, and that he has no claim whatever for remuneration except on a definite arrangement on the subject with that officer. The practitioner will, no doubt, in circumstances of urgency, act upon the request of the medical officer, *ad interim*, until the secretary or chairman of the committee can be communicated with, but he should distinctly understand that by so doing he

acquires no claim—moral or legal—upon the medical officer. He should remember also that if he omits to obtain, at the hands of the committee, or its responsible officer, a definite appointment and a definite understanding as to payment, he in undertaking the duties does so at his own risk, inasmuch as it is the regulation that the guardians “shall, subject to the approval of the Local Government Board, determine the amount of remuneration (if any) to be paid” to the temporary substitutes, and it is therefore quite open to the guardians (and boards have frequently, through a short sighted policy, availed themselves of the power) to refuse to pay anything for such services, unless they have previously contracted with the *locum tenens* for a suitable remuneration for his services.

As regards the continuance of the salary of the dispensary medical officer during his illness, the Council desire to point out that the dispensary medical officer who complies strictly with the terms of the regulations, as above referred to, is entitled, as a matter of right, to receive his salary during the continuance of his illness, and it is not within the power of the guardians to refuse payment, or to make any deduction from the amount, either for remuneration of the *locum tenens*, or for any other purpose.

It is not within the authority of a board of guardians, by any resolution made at the time or previously, to alter the provisions of the regulations, or to create a rule having such effect; and in case of their refusal to pay the *locum tenens*, the dispensary medical officer is not bound in honour or in law to make good such payment, unless he has previously entered into an implied or expressed understanding with the *locum tenens* to that effect, which he is in no way called upon to do.

FEEES FOR EXAMINING A LUNATIC.

An application for two guineas was read to the Ballinasloe Guardians from Dr. Brennan, Kiltormer, for examining a lunatic.

Mr. Hardy thought the charge enormous. He had signed two or three of these orders as a magistrate during the past week, and in his opinion one guinea was sufficient.

Mr. T. D. Mahon considered that the doctor should examine lunatics in his division free of charge, the same as dispensary patients. A case like this occurred in his district before, and he obtained the opinion of the law adviser on the matter, and ascertained that a dispensary doctor was bound to examine lunatics in his district free of charge.

Chairman.—This is the most extraordinary charge I ever heard. Two guineas for examining a lunatic.

Mr. Geoghegan.—Dr. Brennan had to drive from Kiltormer to Ballinasloe with the patient.

Chairman.—He was not bound to do so. I cannot conceive what medical officers are for if not for examining lunatics in their district. They have nothing else to do.

Mr. Horne.—I do not agree with the chairman's observations that the doctors have nothing else to do.

Mr. Mahon proposed that the opinion of the Local Government Board be requested on the subject.

A resolution was adopted asking the Local Government Board to inform the guardians were the medical officers bound to examine lunatics in their district in the same way as dispensary patients?

[A dispensary medical officer must visit, advise, and prescribe for any patient, lunatic or other, for whom he receives a red ticket. Here his duty ends. He is not called upon to certify, and may decline to do so. He cannot, however, receive any fee from the guardians for a certificate unless for a dangerous lunatic committed by

the police, and with the authority of a magistrate, and, even in such case, no fee unless upon the order of the magistrate before whom the lunatic was brought. An order issued by the magistrate must be honoured by the guardians, and they can neither refuse payment nor reduce the amount.—Ed.]

CARLOW UNION.

A COMPLAINT.

DR. O'CALLAGHAN, of Bagenalstown, appeared before the board to complain of the refusal of Relieving Officer Lewis to pay a nurse employed in an urgent case. Dr. O'Callaghan stated that he was called on to attend a woman in her confinement. Her husband came home drunk and pulled her out of the bed, thus endangering her life. When he came again he found it necessary to get a woman to stay with her, and he got the man arrested. Subsequently he sent a note to the Relieving Officer to pay the woman what he considered proper. In reply the Relieving Officer sent an impertinent message to let the doctor who engaged the woman pay her.

The Relieving Officer said he received a note from Dr. O'Callaghan: "Please to pay Catherine Dowling for nursing two nights by my directions, and explain why she was not paid before."

Chairman—Had you got a message to pay before?

Relieving Officer—No.

Chairman—What reply did you send to this?

Relieving Officer—"If the doctor employed you let him pay you." I had no authority to pay anything except by the authority of the board.

Dr. O'Callaghan—It was simply a matter of life and death. The answer I got, and which I complain of, was an answer to the first note I sent to pay her what he thought fair.

Chairman—Here is a requisition from the medical officer to pay a nurse, and the question is did you refuse?

Relieving Officer—I had no authority.

Chairman—Suppose you got a message from the doctor to employ a nurse?

Relieving Officer—I would employ a nurse.

Chairman—You would have paid the nurse employed by yourself, and you would not pay the nurse employed by the doctor?

Relieving Officer—No. It is entirely against the rule.

Chairman—Not even in an urgent case?

Relieving Officer—No.

Relieving Officer Codd—The doctor has no power to employ a nurse without acquainting the relieving officer. If he does appoint a nurse he writes to the relieving officer at the earliest moment, and the relieving officer complies with it.

Mr. Fitzmaurice—I think in this case Mr. Lewis was entirely mistaken.

Chairman—I think so too. The board are surprised that Mr. Lewis should not have complied with the doctor's request, instead of relying on the red-tapeism of the law. You knew it was an urgent case, and in any case you should not have sent back an impertinent reply. The board has expressed its opinion, and no doubt in future Mr. Lewis will take care to conduct himself in a proper way, and not send impertinent messages.

HOUSES FOR WORKHOUSE MEDICAL OFFICERS.

THE following reply has been communicated by the Irish Local Government Board to an application from

the Guardians of the Gorey Union for a loan of money under the Dispensary Houses Act:—

Local Government Board, 22nd May.

SIR.—The Local Government Board for Ireland have had before them the minutes of proceedings of the Board of Guardians of the Gorey Union of the 6th inst., containing a minute of the guardians inquiring whether they can borrow money under the Dispensary Houses (Ireland) Act for the purpose of building a residence for the medical officer of the workhouse, and in reply the Board desire to state that the Act in question provides for the erection of a house or building to be used as a dispensary, or as a dispensary residence for the dispensary district in which such house or building is situate, and in section 2 of the Act the meaning of the expression "dispensary" is defined to be a dispensary house for the medical officer of any dispensary district appointed under the Medical Charities Acts. The Board do not think, therefore, that the provisions of the Act apply to the case of a medical officer of a workhouse who is not also a medical officer of a dispensary district.

IRISH MEDICAL ASSOCIATION.

ANNUAL GENERAL MEETING, 4TH JUNE, 1883.

Report of Council for the Year ending 31st May, 1883.

MR. PRESIDENT AND GENTLEMEN,—

During the year just terminated, your Council held four, and the Committee of Council forty-seven meetings.

INCORPORATION OF THE ASSOCIATION.

Your Council have to report that the steps necessary to have the Irish Medical Association incorporated have been completed during the past year, and that it now enjoys the status, duties, and privileges of an incorporated society. A special report on the subject of incorporation, containing the "Articles of Association," and "Memorandum of Agreement," was circulated amongst the members on the 23rd January last. Your Council, therefore, consider it unnecessary to report further on the subject.

THE MEDICAL REFORM BILL.

Upon the presentation of the Medical Acts Amendment Bill to the House of Lords by Lord Carlisle, in last March, the attention of your Council were most anxiously directed to it, and its provisions were carefully discussed. It was found that the Bill provided effectually for the objects which the Association has advocated through many years past, *i.e.*, (a) admission to the practice of the profession through one central examining body for each division of the Kingdom; (b) reconstitution of the General Medical Council, with direct representation of the profession thereon; (c) increased stringency of the law for the repression of illegitimate practice; and the Council, therefore welcomed the measure as a legislative embodiment of the principles which have long been adopted by medical reformers, and presented to the Lord President of the Privy Council a memorial in favour of legislation on these principles, which memorial will be found in the appendix.

Nevertheless the Bill seemed to your Council to be defective in many of its details, especially in not providing for strict uniformity of education, examination, and examination fee in the three divisions of the Kingdom, in not distributing equitably the funds arising from examination and registration fees, and in not giving to the direct representatives their proper influence and status in the Medical Boards throughout the Kingdom.

Being most anxious to obtain such amendments of the Bill as would meet the threatened opposition of Irish

licensing authorities, the Council requested Dr. Jacob to proceed to London for the purpose of offering to Lord Carlingford the suggestions of the Association as to amendments of the measure. A petition in favour of the Bill, which will be found in the appendix to this report, was entrusted to Dr. Jacob for presentation to the House of Lords, provided the amendments sought for by the Association were conceded. Dr. Jacob had several interviews with the representatives of the Government on these subjects, and having received satisfactory assurances that the clauses which provide for uniformity of system throughout the Kingdom, and for distribution of the surplus funds, would be altered to a more acceptable form, he placed the petition in the hands of Lord Carlingford, who presented it to the House.

When the Bill reached the Committee stage, in April, it was found that the views of the Association on these points had been met by new clauses which, if not identical, are, at least, in the direction of the views adopted by the Association. At that stage a change of which the Association could not approve was made, in that the King's and Queen's College of Physicians was left with an insufficient representation on the Medical Board for Ireland; moreover, at the Board the direct representative had no seat, and, therefore, no direct influence in the important questions which are placed in the hands of the Board for settlement. In these and other minor respects the Bill is still open to improvement, and the Council has not relaxed its efforts to obtain further changes which, if adopted, will bring the Bill into complete conformity with the policy of the Association.

Having passed the House of Lords, the measure has been brought to the House of Commons, and read a first time, being in the hands of Mr. Mundella, Vice-President of the Privy Council. The order for its second reading occupies a place on the notice paper from day to day. At the Committee stage, which will probably not take place for a fortnight after the second reading, numerous amendments will be moved on behalf of the various licensing bodies, and your Council propose, while giving the measure its warmest support, to take the opportunity to press for such changes as are necessary to make the measure perfect in the interest of the public and the medical profession generally.

UNION OFFICERS' SUPERANNUATION (IRELAND) BILL.

The Union Officers' Superannuation (Ireland) Bill of last year was read a second time in the House of Commons, on the 22nd of July, and sent to a Select Committee, empowered to send for persons, papers, and records. The Select Committee met 8th August, when Mr. Herbert Gladstone, M.P., who has charge of the Bill, was elected chairman.

After examination of several witnesses, including Dr. A. H. Jacob, on behalf of this Association, the Select Committee made a special and an ordinary report to the House, bearing date, 11th August, 1882, but nothing further could then be done towards passing the Bill, as the Session had almost expired.

A copy of each of those reports, and a forecast of this year's Bill, containing the amendments suggested, were circulated in the report of Council issued on the 17th October, which was sent to every member of this Association.

The new Bill, however, was not re-introduced until the 5th April last, notwithstanding that the Council pressed Mr. H. Gladstone to bring it forward at the opening of this Session. It now stands for second reading; but, in the present state of public business in the House, and as the Bill has been "blocked" by Mr. Biggar, it is impossible to say when the second reading will take place.

The terms of the Bill are identical with those of its forecast already referred to, but your Council understand Mr. H. Gladstone is considering the advisability of making some alterations which, he says, will tend to

strengthen the position of the union officers. These alterations have not yet been communicated to your Council, but it is understood that Clause 4 will be omitted.

Your Council have made every effort in their power to have the Bill pressed forward without delay, fearing that if it be withheld until the approach of the end of the Session it may be abandoned. They are, however, assured that Mr. Herbert Gladstone is thoroughly in earnest and most anxious to have the Bill passed as soon as possible.

Your Council, in co-operation with the Union Officers' Association, sent delegates to London with a view to dissuade the objecting members from continuing to offer opposition to the Bill, and their exertions appear to have had good effect with all but Mr. Biggar, though it is understood that several amendments will be sought to be introduced, which, so far as they are known to the Council, need not be objected to on behalf of this Association.

In the reports of the Committee of Council, bearing date 17th October and 23rd January last, which were at the time issued to the members of the Association, very full information was contained relative to the Bill, and the steps taken in support of it. Your Council, therefore, feel it will not be considered necessary at present to make further reference to that measure beyond expressing a fervent hope that it may soon be passed. The Council earnestly solicit the co-operation of all the members of the Association in the effort to influence their Parliamentary representatives in favour of the measure, and they suggest that that influence would be best obtained by a personal letter.

NOTIFICATION OF INFECTIOUS DISEASES BILL.

On the 21st February last Mr. Hastings, M.P., re-introduced his Bill dealing with the notification of infectious diseases in England, and your Council at once requested Mr. Meldon, M.P., to re-introduce the Bill on the same subject, which was drawn up and agreed to by this Association in conjunction with the Dublin branch of the British Medical Association, in order that both Bills might be before the House at the same time. Mr. Meldon is only awaiting a favourable opportunity to re-introduce the Bill, the principles of which have been approved of also by the College of Physicians and the Royal College of Surgeons.

Your Council would remind the Association that the principle of this Bill is to make notification of infectious diseases to the sanitary authorities in Ireland obligatory on the householder or guardian of the patient, the medical attendant being at liberty to notify if he voluntarily undertakes that responsibility, and thereby binds himself under penalty to perform it, but not otherwise.

In practice your Council believe such cases will, almost without exception, be voluntarily reported by the medical attendant at the request of the householder, and thus the occurrence of cases of infectious disease will be more generally notified to the sanitary authority than under any other system which your Council is aware of.

MEDICAL WITNESSES AT INQUESTS.

A complaint was made to your Council by a member of the Association, to the effect that the Coroner for his district had recently held an inquest within a very short distance of the complainant's residence, and had brought with him, as medical witness, a gentleman who resides about nine miles from the place where the inquest was held, and who is not practising in the immediate neighbourhood.

This procedure on the part of the Coroner being illegal, inasmuch as the 33rd section of the Coroners' (Ireland) Act, 9 and 10 Vic, cap 37, provides that the Coroner shall summon, as medical witness, "any legally qualified medical practitioner being at the time in actual practice at or near the place where such death happened," your Council instructed Mr. Lloyd, Solicitor to the Association, to oppose the presentment for the fee; and when the case came before the Grand Jury, the Coroner was recommended in future to comply strictly with the law.

IRISH POOR-LAW INTELLIGENCE.

CORRESPONDENCE.

THE GRIEVANCES OF DISPENSARY HACKS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I know your columns are ever ready to plead the cause of the hard-worked dispensary doctor, I venture to point your attention to the hardships of my case. Perhaps on reading it some of my brethren in harness may be induced to bestir themselves and make an effort to remedy some of our greatest grievances.

I hold an appointment in a remote arduous country district. I have two dispensaries to attend to, one of which is several miles from my residence. If I do not wait there for several hours (though nominally I am supposed to have a fixed time), and if a certain patient does not happen to arrive at the dispensary before I leave, I frequently get a *red ticket* next day to attend that patient. Added to this, I am constantly getting red tickets to attend patients who are comfortable farmers, and right well able to pay a reasonable fee; in fact, they are far better off than I am as far as worldly means go. If I get the ticket cancelled I find I am not the gainer in any sense. Faction is strong, and there are several ways of worrying a dispensary hack. After twelve months' hard work, I applied for a few weeks' leave of absence to recruit my wearied frame. Notwithstanding that my dispensary committee are aware that I have had *extra hard duty by night as well as day*, I am refused the leave unless I pay a substitute. This, unfortunately, I can't afford to do and leave home, and I have no doubt there are several in the same position as myself. We are expected to keep up the position of gentlemen—support a house, horse, and servants on the miserable pay of £150 per year, everything in the way of registration fees, &c., included.

How is it that we are the *worst paid, worst treated, and hardest worked* public servants in Ireland? Is there any hope that our condition will be improved? or are we ourselves to blame for not trying to do our best to have some of our most crying grievances redressed? The present ought to be a favourable time if the dispensary doctor would try to enlist some kind-hearted M.P., like the gifted member for Dublin, who would doubtless feel for his afflicted poor brethren if he only half understood their grievances; and when Mr. Herbert Gladstone's Bill comes on the Poor-law union medical officers' friends will have an opportunity of speaking in their defence.

Trusting you will kindly excuse my intruding on your space for the first and last time, and hoping that some one competent to deal with the subject in a practical manner will tell us what we ought to do,

I am, Sir, yours, &c.,

AN AGGRIEVED DISPENSARY HACK.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been a dispensary medical officer for nearly six years, and during that time have endeavoured to make my district one in which the abuse of red tickets was not so glaring as when first appointed.

The population of my district, according to the Registrar-General's quarterly return, is 7,000, and during the past twelve months I received over 1,300 tickets, of which 275 were scarlet runners. My district is not one remote, nor are the people very poor. Will you kindly inform me if the number of tickets I have received is not in excess of the average? I made a calculation to-day, and find that for each patient I attend I receive the sum of 1s. 5d., and very often have to drive five, six, or seven miles to see the same patient several times, and all for the above sum. If the average number of times the 1,300 persons who presented tickets were prescribed for was taken, it would leave a very small sum for each attendance.

Knowing the interest you take, Sir, in our welfare, I trouble you with this note, and I believe until the Local Government Board defines more clearly those for whom dispensary relief is intended, that the present abuse will continue.

I had great difficulty a short time since in getting my committee to cancel the ticket of an unmarried man who was in the receipt of £80 a year. What chance should I then have to get the tickets of others cancelled who are well able to pay a small fee, but having families, and probably being a customer of one of the committee, have medical attendance gratis?

I am a member of the Irish Medical Association, but regret I have never been able to attend any of the meetings, but I think, until the dispensary doctors unite in a body and with a will to have our grievances remedied, that we will still continue the hardest-worked and worst-paid body in the world.

I am, Sir, yours, &c.,

A DISPENSARY DOCTOR.

DISMISSAL OF UNION OFFICERS.

THE following letter has been forwarded by the Council of the Irish Medical Association to every work-house medical officer in Ireland:—

SIR,—The attention of the Council of the Association has been called to a General Order promulgated by the Local Government Board on the 18th of December, 1882, which purports to make a very serious alteration in the terms under which union officers hold their appointments.

The tenure of the appointment of such officers is fixed by sections 31 and 33 of the Irish Poor Relief Act of 1838 (1 and 2 Vic., cap. 56—see Banks's Compendium of Poor Law, pages 21-3), and by the General Order of the 19th of January, 1852, made by the Local Government Board under the authority of this Act (see Compendium, page 722).

Under this Order, it was declared (article 42) that—

“The Board of Guardians may, at their discretion, suspend from the discharge of his duties any union officer, except the clerk, chaplain, or treasurer, and shall forthwith report such suspension, together with the cause thereof, to the Local Government Board; and if the Local Government Board shall remove such suspension, such officer shall remain and continue to discharge his duties.”

Article 38 of the same Order also declared that—

“No officer, having been suspended by the Board of Guardians (and who shall, without the previous removal of such suspension, be dismissed by the Commissioners) shall be entitled to any salary from the date of such suspension.”

These regulations have been altered by the recent order above referred to, and words have been added, which declare that—

“If the Local Government Board shall decide not to remove such suspension, the Board of Guardians may, on being informed of such decision of the Local Government Board, dismiss such officer.”

And again (article 38)—

“No officer . . . who shall . . . be dismissed by the Commissioners, or by the Board of Guardians, shall be entitled, &c., &c.”

In this change of rule the Council of the Association has recognised a disposition on the part of the Local Government Board to reduce the union officer to a condition of dependence for his continuance in office upon the good will of the Board of Guardians, subject only to such protective control as the Local Government Board may be disposed to afford. Under this rule, in fact, the officer is liable at any moment to be suspended by his Board of Guardians, “at their discretion”—without notice to him—without any accusation involving dereliction of or incapacity for duty, and without any inquiry whatever. That suspension would deprive him of his emoluments, and might be continued for an indefinite period, and eventually be converted into an absolute dismissal (with all the disgrace and loss which peremptory removal from office involves) unless the Local Government Board should please to exercise its power of veto, and thus place itself in direct antagonism with the views of the Guardians.

The Council emphatically protests against union medical officers being classed with the workhouse porter or his assistant (who have heretofore been the only functionaries liable to dismissal by the Guardians), and being degraded to a position in which subserviency to the personal, political, and religious feelings of the Guardians would necessarily take the place of zeal, conscientiousness, and capacity, as the means by which continuance in office might be secured. It would, in the opinion of the Council, be altogether incompatible with efficient workhouse administration if the responsible officers were so placed as to be unable to discharge any duty which might be distasteful to a majority of the Guardians, without encountering the immediate risk of dismissal.

The Council, being of opinion that this change in the regulations is both unjust to the officer and unwise in the public interest, is advised by the high legal authority that it is also altogether illegal, and that the Local Government Board has no authority whatever to transfer the power of dismissing an officer to the guardians or to any other persons.

The 31st section of the Poor Relief Act of 1838 says:—

“It shall be lawful for the Commissioners, by their order, to direct the guardians of any union . . . to appoint such paid officers . . . and the Commissioners may, and they are hereby empowered, to define, specify, and direct the execution of the respective duties of such officers and the places or limits within which the same shall be performed, and direct the mode of the appointment, and determine the continuance in office or the dismissal of such officers, and the amount and nature of the security, &c. . . .”

Under this section the Commissioners may direct the mode of appointment, i.e., the details of the method of procedure, but they (and no one else) are to “determine the continuance in office or the dismissal of such officers.”

Again, by the 33rd section—

“The Commissioners may, either upon or without any suggestion or complaint on that behalf from the guardians of any union, remove any paid officer appointed under the provisions of this Act whom they shall deem unfit for, or incompetent to discharge, the duties of any such office, or who shall at any time refuse or neglect to obey and carry into effect any of the orders of the Commissioners.”

It will be noted that the part which the guardians may take towards a dismissal is here restricted to the making of a “suggestion or complaint,” while the removal of the officer is strictly confined to the Commissioners themselves.

Under the authority of these sections the Local Government Board has made the following rule, which, though apparently inconsistent with the addition to Article 38 quoted above, is, nevertheless, re-enacted by the recent order—

“ARTICLE 39.—Every officer appointed to or holding any office under this Order shall, subject to the provisions of Article 40 of this Order, continue to hold the same until he die, or resign, or be removed by the Local Government Board, and every porter or assistant may be dismissed by the board of guardians without the consent of the Local Government Board.”

The Council having submitted the case to their legal adviser, Mr. Purcell, Q.C., County Court Judge for the Co. Limerick, has received the following replies to their queries:—

“1. Counsel will therefore please advise whether the Local Government Board can legally, by Sealed Order or otherwise, empower a board of guardians to dismiss or suspend the medical officer of the union under any circumstances whatever?”

“I am of opinion that the Local Government Board have no power to delegate to boards of guardians any authority to dismiss or suspend the medical officer of the union, and that the General Orders to this effect in the Articles 39 and 40 of the recent Circular are *ultra vires* and illegal.

“2. Should counsel be of opinion that the Local Government Board (though not being able to delegate their power of dismissal) can legally delegate the power of suspending a union medical officer, can a board of guardians exercise such powers of suspension in such a way as to practically dismiss the union medical officer?”

“I find no provision in any of the Acts in relation to the power of suspension. In my opinion, neither the Local Government Board nor a board of guardians have power to suspend a union medical officer, or to deprive him of his salary, except from the date of his dismissal by the Local Government Board, and that the provision in Article 36 of the recent Circular as to the deprivation

of the medical officer's salary from the date of suspension is also *ultra vires*.

"T. A. PURCELL.

"71 Harcourt Street, Dublin,
"15th February, 1883."

This opinion has been recently reconsidered by Mr. Purcell, with special reference to the view of the law put forward subsequently by the Local Government Board, and it has been emphatically reaffirmed by him.

The Council of the Association has in vain solicited the Board to amend the objectionable articles of the recent General Order, or to submit the legality of their action for confirmation by the Law Officers of the Crown; but, having been advised that the validity of the General Order can be tested at law, only by an officer who has been dismissed or suspended by a board of guardians, the Council, therefore, is prevented taking the necessary steps to set aside the rules in question by application to the Court of Queen's Bench.

I am, therefore, directed to communicate to you, as a union medical officer, the legal advice on the subject which the Council has received, and to point out to you, for the information of all union officers, that, from Mr. Purcell's opinion, it follows that a dismissal or suspension by a board of guardians is wholly invalid; and that an officer is entitled (notwithstanding the General Order of the 18th of Dec., 1882, or any vote of the board of guardians founded thereon) to continue in his office, and to receive and recover at law, all his emoluments until he is formally removed by the Local Government under section 33 above quoted, the legal responsibility of such removal devolving solely upon that board.

The Council is prepared to consider the case of any officer dismissed or suspended by a board of guardians under this Order, with a view to proceedings to contest such dismissal at law where the circumstances appear to justify such action.

I am, Sir, yours, &c.,

T. GIOR, Mus.D., Assistant Secretary.

Irish Medical Association, Royal College of Surgeons,
Dublin, May, 1883.

GALWAY UNION.

VACCINATION SUBSTITUTES.

READ the following letter :—

"Arran Island, June 2, 1883.

"GENTLEMEN,—I received a large supply of vaccine lymph from Dublin with a letter directing me to keep up a local supply. This I find impossible to do as the people refuse to let lymph be taken from their children's arms. A policeman named Smirl, whose two children were in the first batch I vaccinated refused to let me have the lymph even after I had read to him the Act making it a criminal offence to refuse. I think if Smirl were prosecuted as an example, it would have a salutary effect on the rest. I mention his name particularly, as he refused both Dr. Roughan and myself in an offensive manner to comply with the Act.

"I am yours obediently,

"W. F. CARMODY."

Mr. McDonagh—I thought it was Dr. Michael Carmody who was appointed to Arran.

The Clerk—So it was so, and this is signed by W. F. Carmody.

Mr. McDonagh—And the doctor who was appointed is away for the last month, and he seems to think he can do what he likes and where he likes.

Dr. Roughan—He said he was Dr. Carmody's brother, and that his brother went away as I took it he was temporarily in the usual way.

Mr. Hernon—There is no one to appoint him. There is no dispensary committee in Arran.

Dr. Roughan—How is a man to act if he wants to go away?

Mr. Burke—Before he went away he should appoint a duly qualified person to act.

Mr. Hernon—He could not appoint any one. It is the board of guardians that should do it.

The following was handed in :—

"I propose we ask the Local Government Board whether a medical officer could in the failure of there being a dispensary committee in his district of his own will and without any leave or reference or notification of his absence to the guardians absent himself from his dispensary district. The medical officer of the Arran dispensary district has now been absent from the Island for over three weeks."

SOUTH DUBLIN UNION.

SUPERANNUATION ALLOWANCE.

Mr. SEXTON moved, "That Dr. G. W. Owens be granted a superannuation allowance of £75 per annum, Dr. Owens having lost his health while in the service of the board." Dr. Owens' health was utterly shattered, and his resignation now, after 15 years' service, would enable the board to make some very necessary alterations in the medical staff of the workhouse, which they had in view for a considerable time.

Mr. Flanagan wished to reduce the vote by £40, giving £35 per annum, which was all he was legally entitled to. They had dealt very leniently by Dr. Owens in not dismissing him, but that was on the statement that he would be voted a very moderate retiring allowance. Now it was proposed to give him more than the very highest in their power. He moved that the allowance be £35 a year.

Mr. Lyons said the board could only vote a superannuation allowance of 15-60ths of Dr. Owens' salary, which would be £37 10s. The Local Government Board could then add 10 years' service, which would bring it up to £62 10s.

Mr. Hearne opposed the vote *in toto*.

Dr. Ormsby said that particular report had been discussed before, and thoroughly thrashed out. He had read all the evidence, and did not think Dr. Owens had been guilty of the slightest carelessness on the occasion in question. It was very hard indeed for a medical officer not to get confused with 200 or 300 children to look after, and the sum of Dr. Owens' offending was that he had given rather confused evidence. He appealed to the guardians not to refuse Mr. Sexton's motion, which would give a professional gentleman a superannuation allowance even smaller than had been previously voted to a gate-keeper.

The amendment, altered to £37 10s. per annum, was then put, when there voted—for, 17; against, 34.

The amendment was therefore declared lost.

Mr. Lyons then moved that the superannuation allowance be £50 a year.

This amendment was also declared lost, and the original resolution being put, was carried by same division—31 to 19.

THE late Mr. Henry Seybert, of Philadelphia, was cremated at Washington, Pennsylvania, on March 7th. Mr. Seybert left 60,000 dollars to the University of Pennsylvania, by which bequest it is stipulated that an impartial investigation of modern spiritualism be made.

IRISH MEDICAL ASSOCIATION.*Report of Council for the Year ending 31st May, 1883.**(Continued.)***WORKHOUSE MEDICAL OFFICERS.**

In a recently-issued order of the Local Government Board, bearing date 18th December, 1882, the Council discovered that the Board delegates to the board of guardians the right to dismiss certain officers of a union, including the medical officer, subject to the confirmation of the Local Government Board; and your Council, considering that the Local Government Board has no authority to delegate that power, and fearing that injustice to the medical officers would result therefrom, instructed Mr. Lloyd, solicitor to the Association, to prepare a case for opinion of counsel.

Mr. Purcell, Q.C., to whom the case was submitted, is of opinion that the view taken by your Council is correct. Your Council, therefore, sent a copy of the case and opinion to the Local Government Board; but the Board still adheres to the terms of its order.

The opinion of Mr. Purcell and the correspondence on the subject will be found in the appendix to this report.

Your Council consider that when a case of dismissal of a medical officer by a board of guardians occurs, the question should be brought into the Court of Queen's Bench, at the expense of the Association, and there decided.

PRISON SURGEONS.

A prison surgeon not long since was summoned by the Crown to give evidence in certain cases then at trial at a considerable distance in another county, and he was thus prevented from discharging his official duties as prison medical officer. He forthwith notified to the authorities that he would be unavoidably absent on Crown business, and requested them to appoint a substitute, but subsequently, by direction of the General Prisons Board, he nominated a substitute, informing that gentleman at the same time that he was not, and would not be, responsible for any remuneration, and he sent a letter to the same effect to the authorities.

The Governor of the prison asked the nominated substitute to state in writing whether he was willing to undertake the duties, and he having by letter consented to undertake the duties, subsequently performed them. During the absence of the prison surgeon certain executions took place in the prison, and the substitute was obliged to perform professional duties, for which he claimed remuneration from the prison authorities, who submitted his application to the Treasury; but the Treasury ruled that the prison surgeon was responsible for the substitute's remuneration, as he had been paid for his services to the Crown during his absence from duty, and that the fees he received were intended to cover such expenses. The prison surgeon denied that he received remuneration for any such purpose, and clearly proved that the fees paid him for his services in the Crown cases were only the ordinary fees which should be paid to any medical witness, whether or not holding any official appointment.

The authorities again submitted the claim to the Treasury, but with no better result, and the substitute (who is also a member of the Association) appealed to the Council to endeavour to enforce payment of his fees.

Your Council consider the matter one of great importance, not only to prison surgeons but to all medical men holding official appointments, as it would be a very grave injustice if medical men, compelled to be absent from duty on Crown business, are thus to be practically deprived of any remuneration for their services, and subjected to inconvenience and loss, while having to hand over their fees to their substitutes.

Your Council, accordingly, have instructed Mr. Lloyd, solicitor to the Association, to take legal proceedings

against the prison authorities to recover the substitute's remuneration—and it is hoped a very important precedent will thus be established.

DISPENSARY MEDICAL OFFICERS—POLICE CASES.

Your Council have frequently been appealed to by dispensary medical officers regarding their responsibilities in connection with police cases, and, as it appears that not only private individuals, but public departments consider it right and proper to take every advantage of the Poor-law system, your Council would again remind dispensary medical officers that they have no responsibility whatever appertaining to their duties as such concerning attendance on any person unless under the authority of a properly issued ticket. If a ticket, signed and filled up by an authorised person, be presented to a dispensary medical officer requiring his attendance on any person he is bound to give his services; but unless such a ticket has been presented he is not bound in any way, and is quite free to exercise his own discretion as to whether he will visit the patient or not. Police cases are *no exception*, and dispensary medical officers who are so hardly used would be right in refusing to give any services to police or other cases unless previously presented with a ticket properly issued by a duly authorised person. In police cases they can hope for no fees, as the authorities do not now recognise such claims; they should, therefore, make it a rule not to give any services until presented with a fee or a properly issued ticket; and if they believe that a patient for whom a ticket has been received is not a poor person properly entitled to dispensary medical relief, they should at the next meeting of the Dispensary Committee represent the facts, and seek to have such ticket cancelled. If the ticket be not cancelled the matter must end there, but if it be cancelled the medical officer is at liberty to sue either the person who improperly issued the ticket, or the person who improperly accepted his services under it.

Such cases are of very frequent occurrence, and if any dispensary medical officer so aggrieved communicates with the hon. secretary of this Association, he will receive full information as to the course he should take with a view to the recovery of his fees.

Numerous instances of recovery of fees for attendance on cancelled tickets have occurred during the past and former years.

FEES OF MEDICAL WITNESSES.

In the intermediate Reports, issued since the last annual general meeting, your Council referred to the subject of fees payable to medical witnesses, and reported that a conference of representatives of the College of Physicians, the Royal College of Surgeons, and of this Association, had been held, which resulted in the adoption of a memorial for presentation to His Excellency the Lord Lieutenant, praying for an amendment of the scale laid down. Your Council have since been in communication with the Right Honourable the Attorney General for Ireland on this subject, and have been informed that under the regulation of 22nd April, 1880, the allowance for hotel expenses of a medical witness in a Crown case has been further reduced from fifteen to ten shillings a night—nothing for the day. Accordingly, only ten shillings is at present allowed for the maintenance of a professional gentleman compelled to absent himself from the sphere of his duties during two days and one night—for one night's absence from home almost invariably involves that of two days also. Your Council are endeavouring to have this injustice to the profession removed, and expect soon to be able to present to His Excellency the Lord Lieutenant a convincing statement that the fees and allowances now fixed are not reasonable for members of the medical profession, and that such limitations would practically exclude all eminent medical men from being employed by litigants, and thereby place the public (especially persons of small means) at a great disadvantage.
